INDEX FOR 1847.

A

Abortion, Disease of the Cervix Uteri, a Cause of, 389, 390
——— Prevention of, 389
Abscess in the Abdomen, 45
——— Buccal, 270
——— of the Iliac Fossa, 381
——— of the Liver, 47[illegible]
——— of the Neck, 372
Abscesses, on the best Mode of Opening, 301
Abstinence, Total, and Medical Testimony, 221, 241, 301, 329, 385
Academie de Médecine, Paris, 161, 243, 300, 385, 554, 580, 634, 665, 711
——— des Sciences, Paris, 160, 241, 299, 385, 420, 559, 581, 635, 666
Accumulative Action of Medicines, 581
Acids, Poisoning by, Treatment of, 191
Aconite, Tincture of, in Rheumatism, 387
Addison, Dr. W., On the Law of the Morphology or Metamorphosis of the Textures of the Human Body, 33, 60, 90, 116, 169, 199, 229, 259, 313, 340, 503
Address, Retrospective, delivered at the Sixth Anniversary of the Reading Pathological Society, 393, 443
——— to General Practitioners, 75
Æther-Advertising, 107
——— Amputation under the Influence of, 16, 81, 108, 191, 620
——— Dislocation reduced under the Influence of, 480
——— Effects of, 276
——— Experiments with, 416
——— Fatal Effects of, 107
——— Inhalation of, on the Circulation, 242
——— Inhalation, 53, 80, 81, 108, 160, 161, 162, 163, 241, 295, 300, 385, 554
——— Abstraction of Blood in the Narcosis from, 163
——— Analysis of the Blood after, 242
——— Apparatus for, 161
——— in Delirium Tremens, 697

INDEX FOR 1847.

A.

Abortion, Disease of the Cervix Uteri, a Cause of, 502, 530
——— Prevention of, 389
Abscess in the Abdomen, 48
——— Fæcal, 270
——— of the Iliac Fossa, 583
——— of the Liver, 475
——— of the Neck, 372
Abscesses, on the best Mode of Opening, 501
Abstinence, Total, and Medical Testimony, 221, 251, 301, 329, 385
Académie de Médecine, Paris, 161, 243, 300, 385, 554, 580, 634, 665, 711
——— des Sciences, Paris, 160, 241, 299, 385, 420, 553, 581, 635, 666
Accumulative Action of Medicines, 561
Acids, Poisoning by, Treatment of, 194
Aconite, Tincture of, in Rheumatism, 387
Addison, Dr. W., On the Law of the Morphology or Metamorphosis of the Textures of the Human Body, 33, 60, 90, 116, 169, 199, 229, 259, 313, 340, 505
Address, Retrospective, delivered at the Sixth Anniversary of the Reading Pathological Society, 365, 393, 449
——— to General Practitioners, 76
Æther-Advertising, 167
——— Amputation under the Influence of, 16, 81, 108, 191, 626
——— Dislocation reduced under the Influence of, 486
——— Effects of, 270
——— Experiments with, 415
——— Fatal Effects of, 167
——— Influence of, on the Circulation, 242
——— Inhalation, 54, 80, 81, 108, 160, 161, 162, 163, 241, 299, 300, 386, 554
——— ——— ——— Abstraction of Blood in the Narcotism from, 163
——— ——— Analysis of the Blood after, 242
——— ——— Apparatus for, 191
——— ——— in Delirium Tremens, 697
Æther-Inhalation, Injurious Effects of, 81, 330
——— ——— in Mania, 528
——— ——— as a Means of Detecting Feigned Diseases, 242
——— ——— in Obstetrical Practice, 139, 243, 516, 698
——— ——— of, in Spasmodic Asthma, 278
——— ——— in Tetanus, 205, 236, 278, 342
——— Inhaled, on the Physiological Action of, 177
——— injected into the Arteries, 299
——— Operations performed under the Influence of, 27, 55, 82, 84, 107, 111, 132, 133, 134, 162, 190, 263, 270, 300, 323
——— Rape perpetrated while under the Influence of, 447
Æthereal Vapour, Action of, compared with that of the Non-respirable Gases, 299
Alæ Nasi, Restoration of, 579
Albuminuria, 269
——— Bitartrate of Potass in, 666
——— Characters of the Urine, the Blood, and the Dropsical Effusions in, 50
——— from Cantharides, 555
——— Extract of Rhatany and Vapour-Baths in, 219
——— Lesions of the Nervous System in the Puerperal State, connected with, 669
Alford, R., Case of Spasma Glottidis, 625
Alkali, New Vegetable, 28
Allison, W., The Medical Registration Bill, 334, 503
Amenorrhœa, Chenopodian olidum in, 106
Ammonia, Benzoate of, in Gout, 416
Amputation, Partial, of the Right Foot, 38
——— Spontaneous, in the Fœtus, 243
Amyot, T. E., Case of Poisoning by the Tinctura Ferri Sesqui-Chloridi, 180, 222
Anæsthetic Agent, New, more efficient than Sulphuric Æther, 656
Anasarca, 269
——— Buchu in, 615
——— treated by Digitalis, gradually increasing the Dose to the fullest Extent, 623
Anderton, C., Case of Amputation of the Arm, performed under the Influence of Æther: Abnormal Distribution of the Brachial Artery, 626

Anecdotes of the Medical Profession, 195, 333, 418, 555
Aneurism, Treatment of, by Compression, 219
——— of the Aorta, 74, 708
——— ——— and other Internal Aneurisms, Sulphate of Quinine in, 475
——— of the Abdominal Aorta, simulating Disease of the Kidney, 598
——— Popliteal, treated by Compression, 124
——— of the left Ventricle, 329
Aneurismal Varix, 48
Ankle, Dislocation of, 470
——— Partial Luxation of, 128
Anniversary Meeting of the Provincial Medical and Surgical Association, 308, 421
Announcement Extraordinary, 223
Anodyne Effects of Tobacco, 583
Antimony, Method of Distinguishing Arsenical Stains from those of, 107
Anus, Treatment of Fissure of, by Cauterization, 360
Aorta, Aneurism of, 74, 708
——— Abdominal, Aneurism of, simulating Disease of the Kidney, 598
——— Dilatation of, simulating Aneurism, 703
——— Rigidity of the Arch of, 303
——— Rupture of, 328
Aortic Valves, Insufficiency of, 217
Aphonia, Galvanism in, 218
Aphthæ, Treatment of, 218
Apoplexy, 3, 329, 385
——— Meningeal, 74
Apothecary, Charge of Unlawfully Practising as, 245
Apparatus for Injuries and Diseases of Joints, 29
Appeal to the Medical Profession on the General Medical Annuity Fund, 188
Appendix Vermiformix, Hernia of, 529
Appetite, Disordered, 467
Appointments, 28, 56, 84, 111, 139, 167, 223, 307, 334, 363, 391, 420, 448, 476, 503, 559, 615, 643, 672, 699, 711
Arachnitis, Tubercular, 693
Arsenic in Cancerous Diseases, 412
——— Detection of, in the Fluid of a Blister, 698
——— Inquiry into the Medicinal Action of, 661
——— Poisoning by, 195
Arsenical Poisoning, Magnesia in, 554; Treatment of, 194
Artery, Brachial, Abnormal Distribution of, 626
——— Internal Carotid, Wound of, and Division of the Par Vagum, 482
——— Posterior Tibial, Rupture of, 19
Ascites, 18, 289
——— Urine in, 52
Asphyxia, 18
Asthma, Spasmodic, Inhalation of Æther in, 278
Astley Cooper Prize, 448
Astragalus, Fracture and Dislocation of, forwards and outwards, 456
Auricle, Right, Dilatation of, in a New Born Infant, 704
Auscultation in Labour, 585
Autoplasty in Vesico-Vaginal Fistulæ, 553

B.

Badely, Dr., Letter from, On Spongio-Piline, 54
Bainbrigge, W. H., Case of Supplementary Spleen, causing Death from the Patient being placed in the Supine Position, in consequence of a Fractured Thigh, 125
——— On the Treatment of Ovarian Dropsy, by Operation, 9
Ballard, Dr. E., Cases illustrative of the Condition of the System which is accompanied by Oxalic Urine, 375, 406, 461, 480
Barham, Dr. C., Case of Poisoning by Oxalic Acid: Recovery, 544
——— Periodical Purpura vicarious of the Catamenia, 455
Banner, J. M., Case of Poisoning by Extract of Belladonna, 98
——— On Varicose Veins and the Ulcers dependent on that State, 171
Barclay, Dr. J., Case of Hepatic Abscess communicating with the Lungs, 67
——— Singular Case of Cutaneous Disease, 655
Barker, Dr. T. H., Removal of the Great Toe and part of the Metatarsal Bone, under the Influence of Æther, 133
Barrett, T., Case of Rigidity of the Os Uteri, treated by Incision of the Cervix Uteri, 684
Barrow, B., Case of Dysmenorrhœa in which the Tincture of Cannabis Indica was employed, with some Observations upon that Drug, 122
——— Description of an Apparatus for Injuries and Diseases of Joints, with Observations and Cases, 29
Bartolomé, Dr., M. M., Extracts from an Essay on Pericarditis, 231
Basham. Dr. W. R., A Course of Lectures on Clinical Medicine, 3, 33, 57, 113, 141, 197, 309.
Bath and Bristol Branch of the Provincial Medical and Surgical Association, 46, 212, 493, 577
——— Pathological Society, 268, 328, 334, 383, 604, 632
Beckingsale, J. E., Abstraction of Blood in the Narcotism from Æther-Inhalation, 163
Belcombe, Dr. H. S., A Sketch of the History and Treatment of Insanity, 225
——— Observations on Secret Poisons, 94
Belladonna, Case of Poisoning by, 98
Bellingham, Dr. O., Observations on Aneurism, and its Treatment by Compression,—(Review,) 522
Benevolent Fund, Report of, 435
Bennet, Dr. H., Inflammatory Diseases of the Cervix Uteri, a cause of Abortion, 587
Benzoate of Ammonia in Gout, 416
Bilious Headache, Cause of, 526
Biographical Notice of the late Mr. Dodd, 103
Bird, Dr. G., Urinary Deposits, their Diagnosis, Pathology and Therapeutical Indications,—(Review), 44
Bird, P. H., Reports of the Queen's Hospital Birmingham, 603
Birmingham Pathological Society, 74, 131, 240, 298, 493, 551, 578, 691, 708

Bite of a Viper, Remedy for, 528
Black, Dr. J., Case of Fatal Phlebitis of the Inferior Vena Cava with Remarks, 63
——— On the Physiological Action of Inhaled Æther, 177
Blister, Detection of Arsenic in the Fluid of, 698
Blisters in Confluent Small-Pox, 105
——— Dressing of, 361
——— Linear, Treatment of Erysipelas by, 301
Blood, Absorption of Oxygen by, 77
——— Analysis of, after Inhalation of Æther, 242
——— Blood, Buffy Coat of, 248
——— Chemistry of, 332
——— Composition of, in Cancerous Diseases, 104
——— ——— in Puerperal Fever, 104
——— Condition of, after Death from Strangulation, 164
——— Effect of Hydropathy on, 218
——— Fibrin of, 248
——— of the Insane, 416
——— Urea in, 383
Bones, Cancer of, 105
——— Diseased, 216
——— Sub-Periosteal Excision of, 554
Bonnet, M., Memoir on the Restoration of the Alæ Nasi, 579
Bottomley, G., Medical Registration Bill, 300
——— Notes of the Famine Fever, as it occurred in Croyden, Surrey, during the months of July, August, and September, of the present year, 701
Boult, E., Pathological Remarks on a Case of Hepatitis resulting in Abscess, 13
Bowels, Obstruction of, 355
Brain, Calcareous Deposit in Arteries of, 328, 329
——— Inflammation of the Membranes of, in Infants, 151, 181, 234, 516
——— Tubercle of, 579
Bree, C. R., Cerebral Diseases of Children, 671
——— The History of an Epidemic Continued Fever, as it occurred in the Parish of Great Finborough, Suffolk, in the Autumn of 1846; related more particularly as illustrative of the Doctrine of Contagion, 676
Bright's Disease of the Kidney, 52, 217
——— Disease, Tincture of Cantharides in, 52
——— Disease, Urine in, 473
Bronchial Glands, Tuberculization of, 580
Bronchitis, Acute, 113, 604
Brookes, Dr. W. P., Operation for Scirrhus of the Left Breast, performed during the Inhalation of Sulphuric Æther, 107
——— Operations performed under the Influence of Æther, 132
Broughton, H. H., Amputation under the Influence of Æther, 191
——— H. H., Case of Traumatic Tetanus: Administration of Æther, 236
Brownbill, T. F., Spontaneous Rupture of the Uterus before Labour, 705
Bryan, J., Cases of Cynanche Stridula, treated with the Sulphate of Copper, 96
Buchu in Anasarca, 615
Buckell, F., Report of the Diseases and Mortality of Romsey, Hants, 320, 569
Burman, J., Case of Ununited Fracture, treated by Galvanism, 654
Burn, Contracted Cicatrices from, 469
——— Possibility of Producing, after Death, resembling those produced during life, 53
Burns, Treacle as a Dressing to, 361, 405, 700
——— Treatment of, with Ammonia, 219
——— and Scalds, Treatment of, 460
——— ——— Best Method of preparing a Report on, 689
Bursæ, Enlarged Subcutaneous, Treatment of, 250

C.

Cæcum and Appendix vermiformis, Hernia of, 529
——— and Colon, Chronic Inflammation of, 271
Calcareous Deposit in the Arteries of the Brain, 328, 329
——— ——— in the Cerebellum, 328
Calculus in a Female, extracted by Dilatation, 539
——— Nasal, 528
Calculi, Vesical, in Infancy, 643
——— ——— Disintegration of, 581
Cancer of the Bones, 105
——— Gelatiniform, of the Stomach, 633
Cancerous Diseases, Arsenic in, 412
——— ——— Composition of the Blood in, 104
——— Tumour of the Stomach, 383
Cancrum Oris, 48
Cannabis Indica, Tincture of, in Dysmenorrhœa, 122
Cantharides, Albuminuria from, 555
——— in Bright's Disease, 52
——— Poisoning with, 417
Carbuncle, 295
Carcinoma of the Heart, 158
——— of the Mamma, 68
——— Uteri, 691
——— Medullary, 577
Cardiac Disease, 605
Caries, Scrofulous, of the Spine, 99
Carlyon, Dr. C., On the Treatment of Burns and Scalds, 460
Catamenia, Periodical Purpura vicarious of, 455
Catamenial Discharge, On the Source of, 264
Cases from Private Practice, 545, 572, 600, 626, 659, 685
——— and Notes from Hospital and Private Practice, 120, 289
Cataract, 182
——— occurring in early Life, 539
Catheterism in Stricture of the Œsophagus, 243
Cerebellum, Calcareous Deposit in, 328
Cerebral Disease, 141, 605
——— Diseases of Children, 589, 671
Cervix Uteri, Inflammatory Disease of, a Cause of Abortion, 587
Chalmers, D., Case of Traumatic Tetanus: Inhalation of Æther, 342
Chambers, Dr., Letter from, Opium in Inflammation, 54

Chest, Instrument for exhibiting the Motions of, during Respiration, 439
Child born at the Ninth Month, passing through an Aperture under One Inch by Two Inches and a Half, 614
Chlorate of Potass in Salivation, 106
Chloroform, Discovery of, 656
——— Effects of, 671
——— Preparation of, 698
Cholera, Destruction of the Poison of, 588
——— Nature of the Fluid Secreted by the Intestinal Mucous Membrane in, 612
——— Progress of, 559, 615, 643, 672, 699
Cicatrices, Contracted, from a Burn, 469
——— Indelible, Question of Identity, 306
Circulating System, Diseases of, 366
Cirrhosis of the Liver, 187, 270
Clark, H., On the Employment of the Power of Elasticity in Surgery, 535
Clinical Medicine, Lectures on, 3, 57, 113, 141, 147, 309, 337
Cod-Liver Oil, 417
——— in Ophthalmia Tarsi, 193
Coffee, Effects of, on Sulphate of Quinine, 502
Cold Water, Treatment of Fever by, 360
College of Physicians, 420, Memorial from, to Sir G. Grey, 25
——— of Physicians of Edinburgh, 699
College of Surgeons, 28, 56, 139, 167, 223, 252, 279, 307, 336, 363, 391, 420, 476, 504, 588, 644, 672, 700, 711
——— Diploma of, obtained under False Pretences, 272
——— Hunterian Oration, 84
——— Jacksonian Prize, 448
Collet, H., Ipecacuanha in the Bites of Venomous Animals, 348
Colloid Disease of the Liver, 240
Collyria, Turpentine, 249
Colon and Cæcum, Chronic Inflammation of, 271.
——— Ulceration and Rupture of, 709
Combe, Dr. A., of Edinburgh, Notice of, 557
Combustion, Spontaneous, 711
Committee appointed at Norwich to enquire into the Publications of the Association, Report of, 1
Compression, Treatment of Aneurism by, 124, 219
——— Treatment of Orchitis by, 148
Conolly, Dr. J., The Construction and Government of Lunatic Asylums and Hospitals for the Insane,—(Review,) 297
Constipation, Obstinate Case of, 206
Contagion, History of an Epidemic Continued Fever, illustrative of the Doctrine of, 676
Convulsions, Puerperal, 600, 626
Cooper, W. W., Practical Remarks on Near Sight, Aged Sight, and Impaired Vision; with Observations upon the Use of Glasses, and on Artificial Light,—(Review,) 102
Copeman, E., Case of Delirium, successfully treated with Sedatives, 401
——— Observations on the Inhalation of Sulphuric Æther, 80
Copper and Lead in the Human Body, 385
Corn-Curer, Manipulations of, 110
Coroner, Abuse of the Office of, 277
Correspondents, Notices to, 28, 56, 84, 112, 140, 168, 196, 224, 252, 280, 308, 334, 364, 392, 420, 448, 476, 504, 532, 560, 588, 616, 644, 672, 700, 712
Cotton, Dr. C., West Norfolk and Lynn Hospital; Complicated Surgical Cases and Operations, 38, 128, 487, 629
Council Report of, 425
——— Prize, 308, 325, 334, 364
Cox, W. S., Clinical Reports of Surgical Cases under the Treatment of, at the Queen's Hospital, Birmingham, 16, 41, 68, 127, 153, 182, 236, 295, 372
Craniotomy, 269
——— Turning a Substitute for, 390, 673
Cranium, Fracture of, in Children, 584
Creosote in Obstinate Ulcers, 388

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

REPORT OF THE COMMITTEE

APPOINTED AT THE

ANNIVERSARY MEETING

OF THE

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION,

Held at Norwich, August 19th and 20th, 1846,

"To enquire whether any and what alteration is required or desirable in the General Publications of the Association."

TO THE COUNCIL OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

Gentlemen,—The Committee appointed at the Annual Meeting of the Provincial Medical and Surgical Association, held at Norwich, in August last, for the purpose of enquiring "whether any and what alteration is required or desirable in the General Publications of the Association," having devoted considerable attention to the subject, and obtained the opinions of many influential members of the Association, think it proper to make a Report to you, founded upon the information so obtained, in order that if deemed advisable, the alterations they are desirous of suggesting may come into force, with the commencement of a new volume in 1847.

Your Committee, deeply sensible of the importance of the duties entrusted to them, and the essential influence which the decision at which they may arrive must have upon the interests of the Association, have divided the object of their enquiries into two parts.

I. As to the propriety of making any change in the *form* and *period of publication* of the *Journal* and *Transactions*.

II. As to the best means of giving the highest possible character to the literature of the Association.

To the first question, upon which your Committee have obtained considerable information, representing the opinions of a large portion of the members of the Association,* they will confine themselves upon the present occasion, reserving the second question for farther deliberation and a second Report on or before the Annual Meeting to be held at Derby, in 1847.

In commencing their remarks, your Committee are desirous of expressing in the strongest terms the high opinion they entertain of the able manner in which the present Editor of the *Provincial Medical and Surgical Journal* has performed the duties entrusted him.

They wish it expressly to be understood that if any fault is to be found with that publication, they consider it arises from the paucity of materials at his command, and the necessary limit of space and matter which the funds of even so large an Association, must enforce in the present form of the *Journal*, and your Committee feel that they are only acting with bare justice to Dr. Streeten, in stating that he has placed the Association under considerable obligation; not only by the ability which he has displayed, but for the gentlemanly tone and highly honourable feeling which he has at all times evinced as Editor of the Society's Publications.

That some alteration, however, is absolutely necessary in the arrangement of the Society's Publications, the opinion of the members who have communicated with the Secretary to your Committee has been unanimously in the affirmative. As might have been expected among so large a body, some difference of opinion exists as to the best method of effecting that change. An analysis of the letters received by the Secretary, shews the following result:—

To discontinue the Journal	2
To publish the Journal weekly	3
To publish the Journal fortnightly, double its present size, with an annual supplement	13
To publish the Journal monthly	3
To establish a Quarterly Journal in lieu of the present publications	2
Total	23

Of the above number, twenty expressed a desire that the "Transactions" should be discontinued as an annual volume;—two that they should be continued as at present; and one gentleman

* Each correspondent with the Committee is considered to have obtained and expressed not only his own, but the opinion of the Associates in his neighbourhood.

advised the discontinuance of the Journal, and the publication of a volume of "Transactions," as at present.

Upon the opinions expressed and the various proposals made by the above gentlemen your Committee would remark :—

I. It is quite impossible to throw any additional force into the Publications of the Society, if the present arrangements continue, because the expenses already incurred, are fully as large as the funds of the Society will admit.

In any alteration, *a saving of expense must be held in view*, to enable the Council to expend the money or a portion of the sum so saved, in obtaining Reports, Essays, Extracts from Foreign Journals, and Papers upon various subjects connected with Medical Science, for insertion in the new publications of the Society.

II. A discontinuance of the Journal would, in the opinion of your Committee, be a most unwise proceeding, and highly prejudicial to the interests of the Society, comprising as it does so large a proportion of Provincial Practitioners in Medicine and Surgery, whose means of obtaining practical information is very great, and whose ability to make that information available to the general body of subscribers is undoubted; your Committee consider, that the Society should not only publish a Journal, but that it should hold a position not inferior to any other similar publication in the United Kingdom.

III. In considering the form of the Society's Publications, it is important to bear in mind the facilities of transmission through the Post to the most remote rural districts.

A Monthly or Quarterly Journal, however, in many respects desirable, could only be issued either through local Secretaries or London booksellers, to both of which means there are the objections of additional expense and much trouble to those gentlemen who already devote considerable time to the affairs of the different Branches of the Association, and it would be impossible by either plan to ensure that regularity in delivery, which is so *important a feature* in periodical literature.

IV. All of the above objections would be obviated by publishing the Journal double its present size once a fortnight, and transmitting it as at present, through the Post. By this change £200 a year would be saved in stamps alone.

With regard to the "Transactions," your Committee are fully sensible of the many valuable papers already published in them by the Society, but they consider that the necessity of their publication is very much lessened by the probability of a discontinuance of the Retrospective Addresses, in consequence of this division of medical literature being now occupied by the excellent publications of Dr. Ranking and Mr. Braithwaite. At the same time your Committee are fully sensible of the probability of papers coming into the hands of the Council, that could only appear in a volume of "Transactions," which though discontinued as an annual publication, might from time to time appear, according to the discretion of the Council.

Considering then the questions submitted to them in all their bearings, and consulting as far as possible the best interests of the Society and the high position it has to maintain in the medical literature of the United Kingdom, your Committee have come to the following resolutions, which they beg to submit to the consideration of the Council.

I. That the "Transactions" of the Provincial Medical and Surgical Association, be discontinued as an annual publication, but appear according to the discretion of the Council, as occasion requires.

II. That the *Provincial Medical and Surgical Journal* be published once a fortnight.

III. That the Journal be increased to double its present size, and that an Annual Supplement be published as soon after the general meeting as possible.

IV. That the most active and energetic measures be adopted to raise the character of the Journal as a medium of conveying PRACTICAL and USEFUL information, and that as one means of attaining this object, a Sub-Editor, with a commensurate salary be appointed.

J. G. CROSSE,
President of the Association.
CHARLES HASTINGS, M.D.,
President of the Council.
EDMUND LYON, M.D.
W. H. RANKING, M.D.
C. M. DURRANT, M.D.
RICHARD CHAMBERS, M.D.
T. HERBERT BARKER, M.B.
PETER MARTIN
W. NEWNHAM
JOHN S. SODEN
JAMES MACKNESS, M.D.
WILLIAM BUDD, M.D.
THOMAS RADFORD, M.D.
C. R. BREE, Secretary to the Committee.

At a meeting of the Central Council held on Friday, December the 18th, 1846, the Report of the Committee appointed at Norwich, to consider the publications of the Association, and several letters forwarded with the Report by Mr. Bree, the Secretary to the Committee, were laid before the Council.

The Council having taken the foregoing

Report and documents accompanying it into consideration, think it right immediately to adopt the recommendations of the Committee, and begin the publication of the Journal fortnightly, at the commencement of the year 1847.

The Council also fully concur in the propriety of the recommendation of the Committee, that a Sub-Editor be appointed, but think it most respectful to the Association to leave that appointment to be filled up at the General Meeting at Derby, having full confidence that the Editor of the Journal will in the mean time make such arrangements for its improvement as circumstances seem to call for.

CHARLES HASTINGS, M.D.

(*Published by order of the Council.*)

A COURSE OF LECTURES ON CLINICAL MEDICINE.

By W. R. Basham, M.D., Physician to the Westminster Hospital.

Lecture V.

Case of Apoplexy complicated with fracture of the temporal bone: Post-mortem appearances; apoplectic clot; ramollissement; extravasation of blood between the pia mater and arachnoid, &c.: emphysematous condition of the lungs; encysted carbonaceous deposit in right lung; spurious melanosis of some authors.—Observations on the coincidence of fracture of the temporal bone, and its importance in a medico-legal point of view.—Chemical characters of the carbonaceous deposit in the lungs; distinction between black pulmonary matter and true melanosis; reference to previously-reported cases; deposit probably occasioned by an impure and loaded atmosphere, principally in miners and others similarly employed. Case of anomalous cerebral symptoms occasioned by ulceration of the ileum and cæcum: Post-mortem report.—Character of the symptoms during life, with general observations on the peculiarity of the cerebral indications in enteric disease.

The case of S. G., an old man seventy-five years of age, who was brought into the Hospital comatose, and who died a few hours afterwards, is, in respect of the *post-mortem* appearances, of some interest to the student in pathological anatomy. He was admitted into the Hospital on the evening of the 31st of October, and when brought in was quite insensible, breathing stertorously; pulse 40, full, labouring and jerking; limbs flaccid and powerless; extremities cold; temperature of the surface low; face pallid and cadaveric; pupils dilated and immovable. He was seen by a policeman to stagger and fall heavily on Westminster Bridge. He was raised up quite insensible by the policeman, and brought to the Hospital on a stretcher. Some blood was taken from his arm, and by midnight his pulse had risen to 72, but he did not rally, and died at three a.m, eight hours after the first seizure. It was subsequently ascertained from his wife, that for the last few weeks he had suffered from vertigo, frequent sensations of giddiness, and a constant dread in the street of being run over; such feelings doubtless arising from the confusion of thought incidental to the state of brain then existing. He, however, had never complained of headache, nor any partial loss of sensation in any part; but had, for many autumns and winters been subject to severe paroxysms of cough, such as occur in asthmatics. He was an old soldier, having been for many years in the Sappers and Miners, and had enjoyed excellent health, his winter cough never preventing his attention to his ordinary avocations.

Post mortem examination thirty hours after death.—Body well formed, limbs proportioned, and muscular system highly developed. An extensive ecchymosis appeared on the scalp, about the posterior portion of the left temporal muscle; there was no external injury of the skin. On reflecting the scalp, the extravasation of blood between the calvarium and scalp was rendered more evident, a layer of coagulated blood being observed between the scalp and bone. No sanguinolent effusion existed between the skull-cap and dura mater, but beneath the latter membrane and the brain, especially on the left side, and extending over the superior surface of the left hemisphere, an extensive coagulated exudation existed. The arachnoid was of the ordinary aspect; beneath it, as well as in the ventricles, some small amount of serous cadaveric exosmosis was apparent. The pia mater was throughout injected, but not highly so, but towards the lower portion of the middle lobe of the left hemisphere, and near the fissure of Sylvius, some blood had extravasated between the pia mater and arachnoid; and at the most inferior portion of the middle lobe, at the point corresponding with the part that lies in the left temporal fossa, the cerebral surface was stained of a chocolate brown, was soft and pulpy to the touch, and when incised developed a small clot of blood, surrounded by softened and yellowish cerebral matter, to the extent of about the eighth of an inch. The vessels of the cerebrum that led from or into this clot, and within a few lines of it, contained coagulated fibrin, distinctly moulded in the vessels, and from which it could be drawn thread-like. No other evidence of diseased action could be traced in the cerebrum or cerebellum, excepting a general hyperæmia of all the tissues. The white matter of the cerebrum appeared of its ordinary firmness, and did not indicate any condition approaching *ramollissement* except in the spot indicated in the middle lobe. The temporal bone of the left side was fractured, the line of injury passing in the direction of the petrous portion of the bone, and running between the groove of the middle meningeal artery and the superior ridge of the petrous process of the bone, it passed through the squamous portion and upwards a short distance into the parietal bone, of the same side. Externally, the fracture had not descended so far as the auditory meatus, nor internally could it be traced to the anterior extremity of the petrous portion of the bone. Some blood was extravasated between the fractured edges. On raising the sternum

the lungs collapsed. They were spongy and elastic throughout; but on the external surface of the superior lobe of the right lung, as also on the middle lobe, were three remarkable emphysematous vesications, the largest equalling in size a hen's egg, the two smaller being about that of a pigeon's. They collapsed instantly on being punctured, and exhibited internally a loose and very expanded cellular structure. The bronchial mucous membrane was pale and of a healthy aspect, but the longitudinal fibres in the secondary divisions were developed in a high degree. It has been said that the lungs were spongy throughout, but two points were exceptions to this, for at the apex of the right lung, and posteriorly on the surface, or within the eighth of an inch of the surface, of the middle lobe, two spots declared themselves to the touch, dense, firm, and carnified, and also distinctly circumscribed. Neither of them exceeded in dimension a moderate-sized filbert. When cut into, these masses appeared encysted, and were bounded by firm cellular tissue; the contents resembled both in colour and consistence, a black carbonaceous pigment. Upon examining a portion under the microscope, the appearance was that of black amorphous grains, like carbon in a state of minute subdivision; bands of cellular tissue seemed to pass through this carbonaceous deposit. The bronchial glands were of ordinary appearance. The remaining viscera presented nothing worthy of note, except that the kidneys were much lobulated, and both were encysted, the left contained a serous cyst, the capacity of which was equal to ten ounces.

There are several circumstances and conditions in this *post-mortem* record of considerable interest to the student as well as to the more experienced practitioner. First, the state of the brain as expressive of the apoplectic condition; secondly, the existence of fracture through the temporal bone, presenting a complication of much medico-legal interest; and, thirdly, the state of the lungs as indicative of interlobular emphysema, with the extreme development of the longitudinal fibres in the bronchii, expressive of the asthmatic paroxysms during life, together with the presence of two encysted deposits of carbonaceous matter in a state of minute division, and a question raised thereon,—whether the circumstances under which he may have been placed as a Sapper and Miner could in any way explain the existence of these unusual appearances in the pulmonary tissue,—whether working oftentimes in an atmosphere loaded with particles of carbon suspended in the air, (as would be the case in many mining operations in military works,) could in any way have tended to the development of these deposits.

Let me first direct your attention to the state of the head, the scalp, and brain. In the former we have evidence of external local injury; in the latter proofs of an apoplectic cyst are unquestionable. I am anxious to point out to you the limit of the indications by which these two conditions are proved. The extravasation of blood beneath the scalp under the temporal fascia must have arisen from external injury, and when we find on minute examination that the temporal bone is fractured, the fact is established beyond doubt. On examining the state of the brain and its meninges we observe blood extravasated beneath the dura mater, between it and the arachnoid, not upon the dura mater, between it and the bone. Blood has also effused between the pia mater and arachnoid, and at the most inferior point of the middle lobe of the left hemisphere, at the concavity of this lobe lying in the temporal fossa, and close adjoining to the line of fracture; the cerebral substance is observed discoloured, of a purplish brown, and the spot being opened, displays a clot of blood, surrounded by medullary matter—soft, pulpy, and of a brown-ochrey hue, presenting the condition usually recognised as *ramollissement*. These appearances are evidences of the apoplectic seizure. The presence of an apoplectic clot or cyst, without accompanying effusion of blood between the meninges or into the ventricles, is not incompatible with life. The cicatrices of many such cysts have been frequently observed in the brains of apoplectics. In a case examined by me two years since no less than five such cicatrices or remains of apoplectic cysts were observed, two in the left hemisphere, one in the thalamus, one in the corpus striatum of the opposite side, and one in the cerebellum. These were severally in various stages of obliteration, and corresponded in number and appearance to five distinct apoplectic fits that this individual had suffered from during the preceding three years. An apoplectic cyst, or sanguinolent clot, even though surrounded by a limited amount of softening, does not necessarily involve the cessation of the vital processes; but in the case before us the apoplectic condition of the cerebral substance was accompanied by effusion of blood between the pia mater and arachnoid, and between the arachnoid and dura mater. It is this transudation of blood beyond the cerebral mass and upon the surface, or into the cavities, of the brain that constitutes for the most part the fatal lesion in apoplexy; for experience proves that so long as the effusion remains encysted and confined to the cerebral mass, although paralysis usually supervenes, yet the organic functions still continue, those of sensation and motion being impaired. But when the blood escapes beyond the cerebral substance, and is transuded between the meninges, or into the ventricles, the functions of organic life appear to be incompatible with such lesions, and death speedily ensues. It follows from this that transudation of blood between the pia mater and arachnoid, or between the latter and the dura mater, must be accepted as a more fatal lesion than the existence of a clot in the medullary mass; in other words, a simple sanguinolent cyst in the cerebral substance is of less vital moment than one occurring in the superficies of the convolutions, and accompanied by escape of blood between the vascular and serous investments of the hemispheres.

I directed your attention to the soft ochrey-brown pulpy state of the medullary substance that surrounded the clot. This softened condition of the cortical portion must not be viewed as the result or effect of the sanguineous clot, but rather as a condition preceding, and predisposing, if not accessary, to the formation of the apoplectic cyst. There could be little doubt but that the brain had been undergoing some morbid

changes at this spot for some time previous. The mental symptoms spoken of by his wife indicate this. The frequent giddiness and uncertainty of gait, hesitation of manner, and a dread when walking of being run over, spoke of some changes going on in the encephalon inimical to its continued integrity. The opinion of the best pathologists is, moreover, in favour of this view,—that the *ramollissement* surrounding an apoplectic cyst must be admitted as a condition preceding, not following, the formation of the clot.

The coincidence of fracture of the temporal bone imparts to this case an additional interest; and had the circumstances under which he received this injury been less public, or had any mystery existed, as to the manner in which the accident happened, some questions of great medico-legal moment would have arisen, and would have embraced these considerations,—whether the apoplectic effusion, or the extravasation from the fracture, was the cause of death; and the question would comprehend the equally important one,—whether a blow, or any external violence sufficient to fracture a bone, could possibly induce such an apoplectic cyst as existed in this case, or whether it was not more probable, that the apoplectic fit first supervening, gave rise to insensibility and sudden loss of muscular power, under which the body might fall heavily, and thus account for the external injuries. In the case before us, the facts and circumstances under which the patient was found are sufficiently public and satisfactory, and preclude any speculation as to the probable origin or relation of any of the pathological appearances; but if this man had been found insensible and alone, and robbed, or any doubt had hung over the origin of the accident, then such questions as I have propounded would necessarily suggest themselves, and would imperatively demand a clear and explicit solution to satisfy the demands of public justice. In a medico-legal enquiry, the first point to be determined would be the nature and extent of the external injuries. Contusion of the scalp, with extravasation of blood beneath the temporal fascia and fracture of the temporal bone are present, all of which might equally result from a blow or a fall. These local injuries are unquestionably of themselves sufficient to cause death; but on examining the state of the brain, an apoplectic cyst is found, with transudation of blood between the pia mater and arachnoid, a lesion also incompatible with life. An important point thence arises, to which of these two competent causes are we to attribute the death of the person. I quote the following passage from a note in *Beck's Medical Jurisprudence*, p. 330. Article wounds:—

"If effusion of blood be found between the dura mater and the skull, and if a bruise on the scalp corresponds to the part, we may conclude that it has been caused by the blow; but if blood has been found between the dura mater and the brain, though we should discover the marks of blows, or even fracture of the skull, still the question may be, 'might not the patient have been attacked with apoplexy during a struggle?'" A case is then quoted from Dr. Cheyne in illustration.

The unequivocal proofs of apoplexy, therefore, in this case would be accepted as satisfactory evidence,—that death was more likely to have been promoted by this cause than by the local injury; and this inference would be further established by detailing the condition of the brain surrounding the apoplectic spot. For it has been already shown that this softened discoloured condition of the cortical substance must have existed antecedently and could not in any way have been caused by the apoplectic effusion, still less by the local injury. The entire medico-legal question thus turns on the nature and extent of the cerebral complication in conjunction with the local injury. If the cerebral lesions are sufficient to cause death, and capable of being produced independently of external injuries, then we are bound to suppose that death ensued from causes originating in the brain, constitutionally produced, If, on the contrary, the cerebral conditions are such, that it is more likely they were caused by the external injury, such as simple effusion of blood, unaccompanied by any express circumstances proving a spontaneous origin in the system itself, we must then declare the external wound to have been the immediate cause of death, and death by violence, not from natural causes, would then be recorded.

The state of the lungs in this case were an excellent illustration of the conditions of interlobular emphysema, and the hypertrophied condition of the longitudinal fibres of the bronchi, even down to the smaller subdivisions, spoke of the existence of asthma during life, which was verified by the wife's account of the paroxysms of cough, to which he was subject. But there was one other condition of these lungs, or rather of the right lung, of peculiar pathological interest. In examining the lung of this side to determine its spongy crepitating condition throughout, the sense of touch was arrested at two spots, which felt hard and circumscribed. Their situation has been already noted: they appeared encysted, being surrounded by cellular tissue of a dense structure, and when cut into developed a black carbonaceous pigment, which, when examined under the microscope appeared to consist of amorphous granules of carbon, in a state of minute division. This deposit was not affected either by hydro-chloric acid, nitric acid, nor by liquor potassæ; but I much regret now that I did not submit it to more minute chemical analysis, with a view of determining its positive chemical properties. It was miscible with water, stained the fingers black temporarily, and the negative action of the acids and alkalies on it testify to its being similar to carbon, and if carbon, then in all probability, a deposit of carbonaceous matters inhaled by the respiratory function; for it had not the appearance of a matter deposited by secretion, nor any similarity to melanotic disease. Laennec has distinguished black pulmonary matter from true melanosis, one of the characteristics of the former being its isolated situation in the pulmonary tissue or bronchial glands, and its distinct carbonaceous character when chemically treated, while the latter is seldom or never found confined to one organ, but is distributed through several, and possesses distinct chemical characteristics of organic origin. Laennec also referred

the presence of the black matter found either in the bronchial glands or the pulmonary tissue to the inhalation of carbonaceous particles in minute division, floating in the air, and originating from the ordinary processes of combustion, whether for the production of artificial light or warmth, Laennec even considered the grey mottled appearance of the surface of the lungs of most patients to be dependent on minute quantities of carbonaceous matter, deposited and scattered irregularly through the lungs; and this mottled aspect of the surface he considered to be more prevalent in the inhabitants of towns than in those who dwell in the country, and he cites the appearance of the lungs of infants as corroborative of this view, in whom it is observed that the lungs are of a rosy pink and deficient in any trace of the mottled condition.

A case reported by the late Dr. J. C. Gregory, of a patient who died in the Edinburgh Infirmary, may be cited as one of the earliest recorded and best illustrated cases of this black deposit. In that case, "the lungs were found of one uniform black carbonaceous colour, pervading every part of their substance. The right lung was much disorganized, and exhibited in its upper and middle lobes several large irregular cavities, communicating with one another; a considerable portion of the pulmonary substance surrounding them was dense, hepatized, and friable. The bronchial glands were not enlarged, but partook of the same black colour as the substance of the lungs." The black matter was analyzed by Dr. Christison, and after determining the action of hydrochloric and nitric acid, and liquor potassæ upon it, and observing the negative results produced by each of them, a portion of that unacted upon by nitric acid was well washed, dried, and introduced into a small tube retort, with the beak subsequently drawn out fine; the bulb was heated to a dull heat, and all the products of the distillation from coal were obtained,—an inflammable gas, a volatile fluid like naphtha holding in solution a crystallizable matter identical in character with napthaline. This analysis proved the carbonaceous deposit in this case to be coal dust in a state of minute division. The patient had been accustomed to work in the confined limits of a coal mine, and was constantly respiring an atmosphere impure and loaded with carbonaceous particles.

It is, however, to Dr. W. Thomson's report in the *Medico Chirurgical Transactions* for 1837 and 1838, vols. 20 and 21, "On black expectoration and black matter in the Lungs," that the profession is indebted for a more comprehensive account of the presence of carbonaceous deposits in the lungs of those engaged in the coal-mining districts. His paper furnishes unquestionable proof that the deposit is of more frequent occurrence among, if not specially confined to, those who work in mines, or in places the atmosphere of which is charged with carboniferous dust or vapours; those who work above ground, or in a purer atmosphere, seldom exhibiting these accumulations except in a trifling degree, and then principally confined to the bronchial glands. Dr. W. Thomson's record of cases also proves, that though many fall victims to the irritation which these extraneous particles create in the pulmonary tissue, and die with many of the symptoms of phthisis, and whose lungs are found disorganised after the manner of those in whom tubercles are deposited, yet there is a class of cases in which the lungs are infiltrated with black matter without any marks or symptoms of pulmonary disease developing themselves during life. Among several cases of this class recorded, is one of a coal-miner, who died at seventy, and who had always enjoyed excellent health. He appears only to have suffered from some slight pectoral symptoms analogous to chronic bronchitis or pulmonary catarrh, and his death was occasioned by some hepatic disease. "Both lungs presented a perfectly black appearance externally, and when cut into, throughout both lungs were felt and seen hard masses of black matter, from the size of an almond downward. In the left lung were several chalky bodies encased in black matter. There was no black matter in the bronchial glands." From the record of these cases it would appear, that those who work in situations and at employments in which the air is loaded with dust or carbonaceous particles, are more subject to these black accumulations than others; and from the chemical nature of these deposits, we can hardly refuse to admit that their contents are extraneous, and the result of inhalation from without.

The occupations and duties in early life of the individual whose case has suggested these remarks, were especially calculated to facilitate these deposits; for although we have no history of his services, yet, as a Sapper and Miner, dying at the age of seventy-five, we may fairly infer that in early life he was actively employed in those military duties peculiar to his branch of the service, which would place him in circumstances oftentimes identical with the coal-miner, where blastings are frequently employed; and he would thus be equally exposed to all the conditions most favourable to the deposit of these carbonaceous accumulations.

The case of the poor girl, whose body has been examined this week, deserves also some remarks; for this case illustrates how extensive ulceration may proceed in the ileum and cæcum, without developing any well-marked symptoms for some period preceding death; and it also exemplifies how, even in the adult, the symptoms may indicate cerebral excitement and inflammation, rather than intestinal ulceration.

E. W., aged 19, a servant, was admitted November 24th. On being brought into the physician's room, she exhibited a dull, almost idiotic, manner, answering no questions, looking vacantly about her, but exhibiting no indications of physical debility or muscular prostration, for she walked to the hospital with her sister, and nearly up to St. Margaret's ward, unassisted, her condition indicating some obscure cerebral derangement. On being examined in the ward, the pupils were observed to be much dilated, the balls protruding, and she shrank quickly and sensitively when they were pressed. The skin was hot; the pulse frequent; the abdomen tympanitic, but soft and yielding, and no epigastric or cæcal tenderness could be detected; the tongue was red, but broad, and clean, and moist. She was ordered Hydrarg. Chloridi, gr.

iv.; Pulv. Ipecac., Comp., gr. vj., statim; with fever draughts every four hours.

The next day the pulse was 140; skin intensely hot; pupils insensible, being much dilated; the respiration much accelerated; stares vacantly about; answers no questions; protrudes the tongue when desired, which is clean and moist; face much flushed; eye-balls sensitive; skin bedewed with a copious perspiration; pulse 136, soft, but incompressible; the urine and fæces have been passed unconsciously, the latter have the ordinary aspect. The head was shaved; cold lotion applied. Antim. Potassio-Tart., gr. ¼; Opii Pulv., gr. ss., quartis horis.

The report on the 28th states that she passed a quiet night, but did not sleep; answers no questions; some little incoherence and muttering to herself; bowels have not acted, and the bladder was relieved by the catheter. Enemata were administered. At night on the 26th she appeared better, and was temporarily sensible, answering one or two questions in monosyllables. The night was passed quietly, and in the morning she was reported as much better; she even sat up in bed, and took a little arrowroot in the morning of the 27th, but soon after she suddenly became pale and death-like. There was no convulsion; but the pulse was small and rapid, and then imperceptible; the surface was bedewed with a copious death-smelling sudoresis. She gradually sank and died an hour after the change that appeared at 10 a.m.

Sectio cadaveris thirty hours after death. The body was well formed; no emaciation; on the contrary, the limbs were rounded and plump from subcutaneous fat. The cavity of the cranium exhibited well-marked indications of acute hyperæmia in all its parts; the vessels of the dura mater were much injected; the arachnoid was diaphonous and natural; the pia mater was highly injected, so much so as to present the appearance of a dusky-purple; the substance of the brain was natural, except the presence of innumerable red spots from the divided vessels, and the cortical part assumed a dark almost madder hue; the ventricles contained no more serum than could result from cadaveric exosmosis. The lungs and heart were healthy; the stomach and intestines distended with flatus; the lining membrane of the stomach was pale and natural in appearance, but easily detached and peeled off; the duodenum and jejunum was also remarkably pale and exsanguineous. The lower eighteen inches, however, of the ileum was studded with many warty ulcerations, this appearance arising probably from the enlargement of the follicular glands in the first instance and their subsequent ulceration; one ulcered surface wae more than an inch in extent, was oval-shaped, its margins considerably elevated above the surrounding membrane, and its cavity containing a dirty spongy matter, like gangrenous cellular tissue; the surrounding portions of mucous membrane were injected. The entire space of the cæcum was involved in one large, jagged, irregular, wart-like ulcer, its surface being wrinkled and covered with the same conditioned substance attached to the ulcers of the ileum. A nail's breadth beyond, the cæcum and the mucous membrane of the colon presented the same pale state of the mucous membrane that marked the stomach and duodenum. The fimbriated extremities of the Fallopian tubes were both intensely congested; the ovaries contained minute serous cysts; the liver, kidneys, spleen, and pancreas, had a healthy appearance.

It is remarkable that inflammation and ulceration of the intestines are oftentimes accompanied by indeterminate and most obscure symptoms. From our knowledge of the functions of the intestines, and of the important part they perform in the animal economy, we might almost infer that the slightest deviation from healthy action would be expressed by some unequivocal symptom, which would emphatically declare the seat of the derangement; but such is not so. Of all the organs of the body under the influence of disease, the intestines exhibit the least expressive and most variable symptoms. This arises from the wide-spread influence exercised by the intestinal function over other and distinct organs, and the powerful sympathy excited in them by intestinal derangement; hence it is that certain portions of the intestinal tube, whether in a state of simple congestion, or even passing into ulcerative disorganization, may almost be said to possess no true pathognomonic characters, oftentimes giving rise to symptoms simulative of other diseases, and thereby masking the real though latent disorder.

The case before us is a well-marked example of the disguise under which intestinal mischief may present itself, and proceed to a fatal termination without developing any prominent abdominal indications. Except some trifling tympanitis of the abdomen all the symptoms declared for cerebral rather than abdominal disease.

It is commonly asserted in books that inflammation of the intestines in adults is easily determined and recognised in every part of their extent; but that in infants, and in the earlier periods of life, it is admitted that much obscurity often hangs over the symptoms. In children acute enteritis is frequently expressed by cerebral symptoms, but in adults, on the contrary, the greatest variety of sympathetic irritations develope themselves, and as a general rule it may be stated that the enteritis of children is more frequently expressed by cerebral irritation than in the adult; yet enteric disease in the latter not unfrequently declares itself by symptoms chiefly cerebral. It is usually asserted, and practically it is true, that inflammation and disease of certain distinct portions of the intestinal canal are sufficiently well-marked by specific pathognomonic sympoms. Thus, in inflammation of the duodenum, or as the stomach is usually involved in gastro-duodenitis, this condition is declared by the presence of more or less jaundice, pain and fullness over the region of the duodenum, irritable stomach, loaded urine, and clay-coloured dejections. If the stomach be alone the seat of inflammation, vomiting (obstinate and constant,) of a green bilious fluid, is the most prominent symptom. If diarrhœa, long-continued and exhausting, present itself, experience justifies us in fixing on the colon as the seat of the disease. Thus, when these isolated portions of the alimentary canal are involved in inflammatory or dis-

eased actions, the signs by which they are recognised, and the symptoms by which they are accompanied, are sufficiently distinct and unequivocal. *Post-mortem* examination testifies to the truth of this point in semeiology, for after frequent and obstinate vomiting the stomach is found inflamed and injected, and after long continued diarrhœa the mucous membrane of the colon is found in a similar condition. Now, conversely, this is true also, viz., if no vomiting or diarrhœa be present during life, we may safely infer the absence of any inflammatory condition of the stomach or large intestine. In the case before us there was neither vomiting nor diarrhœa, and the dissection proved the stomach and colon to be natural in appearance, and entirely free from any trace of disease.

The symptoms usually present in adults when the middle portions of the intestinal tube, the jejunum and ileum, are the seat of disease, are those of continued fever—hot skin; quick pulse; urgent thirst; tongue red, parched and dry; tympanitic abdomen, with iliac tenderness; great physical prostration and mental stupor. It is very rare that inflammation of the ileum in the adult proceeding on to ulceration, is unaccompanied by some of these symptoms more or less prominently expressed, and when a case occurs in which all are absent, and in the place of them a clean moist tongue, skin not elevated in temperature, no physical prostration, no abdominal tenderness, some slight resonance of the abdomen, a sharp quick pulse, with a remarkable amount of stupor and sudden death, with *post-mortem* proofs of extensive ulceration in the ileum and cæcum, and no cerebral lesion beyond congestion, the record of such a case becomes interesting from its deviation from ordinary examples, and is of much value and moment if it presents any analogy to cases of similar irregularity recorded by others. Dr. Stokes records a case of enteritis, in which extensive ulceration existed in the lower portion of the ileum; neither vomiting nor diarrhœa were present during life, and the stomach and colon were found perfectly free from vascularity. "In this case," he says, "the absence of vomiting and of diarrhœa in the more advanced periods is extremely interesting as connected with the healthy state of the stomach and colon." In the case under consideration, there was neither vomiting nor diarrhœa during life; the stomach and colon were free from all vestiges of disease, yet the ileum and cæcum exhibited many ulcerations in the lower portion of the ileum, and the cæcum was in a state of complete disorganization. Again, Andral relates a case of a patient, aged thirty-five, "who was attacked with pain of the head, followed by great loquacity and exaltation of ideas, and other symptoms of cerebral excitement. The tongue was natural and the abdomen soft *and not painful*. He had soon after furious delirium and indications of strong determination to the head. Copious general bleeding, and the application of leeches to the neck produced no alleviation, and the patient expired suddenly in the midst of a general spasm. The only local symptom of an affection of the bowels during the disease was a slight diarrhœa. On dissection, the brain and its membranes were found perfectly healthy, but the lower third of the ileum was in the state of acute inflammation."*

As it is not doubted that much obscurity frequently attends inflammatory and ulcerative disease of the small intestines, it is of great moment to determine what signs are of most value by which we can distinguish the latent disease among the many sympathetic and anomalous conditions that involve it in obscurity. Is there any one specific indication on which we can uniformly depend? I believe not; nor do I believe that any series of symptoms is sufficiently constant to be relied on, as distinctly expressive of enteric ulceration. We have already seen, that although a hot skin, dry tongue, thirst, abdominal tenderness, and tympany, with indications of stupor, when present, may be accepted as proofs of enteric disease, yet the present case, as well as others elsewhere recorded, unquestionably declares, that ulceration may exist without any such catenation of symptoms. Now although ulceration of the ileum and cœcum may exist without a hot skin, with a moist, clean-looking tongue, without any morbid thirst, and with dejections, even natural and bilious in appearance, and no abdominal tenderness or tension, yet there are accompanying symptoms, chiefly cerebral, which, though oftentimes obscure, will, if closely watched, tempt us at any rate to doubt the presence of inflammatory action in the brain; and if so, to cause us to direct our attention to some other organ for an interpretation of this sympathetic irritation of the brain. I am anxious to ascertain if there be any peculiarity about the cerebral symptoms, by which we can distinguish them from those which arise in true inflammation of the brain and its meninges;—whether any distinction can be made between the symptoms developed in encephalitis or arachnitis, and those witnessed in cerebral irritation from enteric disease. In attempting this distinction, we must confine ourselves strictly to the mental symptoms; for the state of the pulse, skin, tongue, and excretions could only testify to the amount of concomitant fever. In cerebral inflammation, there is usually observed wild raving delirium; a great amount of physical violence; incoherence of ideas; extraordinary hallucinations; sleeplessness and general restlessness: these are succeeded by a condition more or less indicative of coma. The cerebral symptoms developed as sympathetic with intestinal disease, are characterised usually by a peculiar stupor; there is no raving delirium; the patient lies passive, dull and motionless; can be roused to temporary consciousness; will protrude the tongue when energetically required to do so; the nights are sleepless, but the patient remains quiet and apparently undisturbed; the pupils are oftentimes dilated and the eye-balls glazed. These are the usual characters of the symptoms in sympathetic irritation of the brain from abdominal irritation. Yet it is evident that these symptoms cannot always be relied on,—as in Andral's case, the symptoms were of exaltation of all the mental faculties, with incoherence and delirium. I cannot but advise you, however, to suspect something other than cranial disease, if a case presents itself with

* "Cyclopœdia of Practical Medicine."

the peculiar stupor which I have described, and which has not been preceded by any more acute symptoms of cerebral inflammation; if, in addition to this stupor, there be abdominal tension and tympanitis, you may with great reason suspect the head-symptoms to be sympathetic; if, also, there be tenderness about the right iliac region on pressure, the patient shrinking when pressure is made there, and if there be a hot skin, rapid pulse, red dry tongue, with craving thirst, you need not doubt but that you have a case of enteric disease to treat, and that with such symptoms your prognosis cannot but be otherwise than unfavourable.

ON THE TREATMENT OF OVARIAN DROPSY BY OPERATION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

"Nunquam aliud natura, alind sapintia dicit."

I feel indebted to your correspondent, INQUIRER, for an opportunity of supplying an important omission in the review I took of my case of ovarian dropsy published in your Journal, the 16th of last December. If I rightly appreciate the tenor of his enquiries, he wishes to know *the data* on which I have arrived at my conclusions respecting the comparative absence of danger, and the superior advantages attending operations conducted on the principle I advocate. To form a complete collection of the cases which bear directly or indirectly on the exemplification of this principle, scattered as they are over such a wide field of research, would be a task incompatible with the discharge of my professional duties. The subjoined abstract, though incomplete, will however, I trust, not merely satisfy him that I had sufficient grounds on which to base my deductions, but also attract and fix the attention of my professional brethren to the subject, and induce them to give the operation in question a fair trial.

EIGHTEEN CASES OF OVARIAN DROPSY, TREATED ON THE PRINCIPLE OF MR. BAINBRIGGE'S OPERATION.

London Medical Gazette, Vol. 18, p. 469.—An operation for relief of ovarian dropsy is recorded. An incision of about an inch and a half was made below the umbilicus; the sac was opened to about the extent of three inches, and evacuated, and a ligature passed through it, and secured externally, in order to keep the sac in contact with the abdominal parietes. There was a discharge for about a month, when it ceased, and the opening closed. *The result was a permanent cure.* By *Mr. Currie*, Liverpool.

Memoires de L' Académie Royale de Chirurg., tom II., p. 431 to 444, An. 1753.—A detailed report of two cases by Le Dran, in which an incision was made into the cyst, the contents evacuated, the wound kept open, and the suppurative process established in the cyst. *The result was a permanent cure*, a fistulous opening remaining in one of the cases for two years, and in the other for the remainder of the time up to which he had observed the case.

It appears that subsequently to these two successful cases Le Dran was in the habit of operating in this way. He says, he always found the fistula remained permanent, except in the solitary case above given, where it closed in two years. To keep open the communication with the interior of the cyst, he sometimes employed a tent, at others left the canula or even leaden tubes in the wound, and occasionally used injections. He remarks on the inefficacy of tapping, and then says "J'ai osé tenter une nouvelle route et le succès a répondu a mon espérance," from which it is natural to infer that he was eminently successful.

Lancet, Vol. 13, p. 879.—Allusion is made to the above cases; and *a similar one* by Portal is mentioned, in which *a cure followed.*

Lancet, Vol. 20, p. 603.—A case by M. Rigollot, of St. Etienne, is given, in which after the use of the trocar irritating injections were employed. *The cure was completed in a month.*

London Medical Gazette, Vol. 26, p. 349.—A case of ovarian dropsy, treated by tapping the tumour in the vagina. Although intended merely to liberate the fluid by tapping, the *wound kept open*, and a continuous discharge took place. *Permanent cure.*

Edinburgh Medical and Surgical Journal, vol. 16, p. 367—A case of operation by incision,—closure of the opening by the surgeon,—spontaneous re-opening of it subsequently, of about the size of a small pea from which, on the slightest exertion, matter flowed freely, which the operator considered *an unusual effort of nature* for her relief; it was followed by *permanent subsidence of the tumour and restoration of health.* By Dr. Mc'Keever, Lying-in Hospital, Dublin.

In my case, as in the above, I regard the continuance of the discharge as an *effort of nature* to suppress any further development of the disease.

Medical Times, vol. 8, p. 233.—A case is quoted as having been given by Dr. Ollenroth, in which the wound was kept open, and the contents of the sac allowed to escape through it for a considerable period; *followed by a permanent and radical cure.*

London Medical and Surgical Journal, vol. 4, p. 428. —*A case of permanent cure* is recorded, by an incision into the sac, partial evacuation of its contents, and a tent left in the wound. Through the opening a fluid and portions of the cyst from time to time were discharged. The opening remained fistulous.

London Medical and Surgical Journal, vol. 6, p. 320, —A case, by Mr. Langley, of ovarian dropsy, complicated with pregnancy. He punctured the cyst in the vagina, the contents came away, and the woman was soon after delivered. The editor remarks upon it:—"The result of the case warrants paracentesis per vaginam; the advantage would be *the gradual and constant discharge* of the fluid by an opening so dependent." Of course he must allude to the fluid draining off as soon as formed again in the cyst, and

have supposed such to have been the case in the present instance.

Philosophical Transactions, Vol. 33.—Dr. Houston's Case of Operation for Ovarian Tumour. He found, on introducing the trocar, that no fluid came away; but on making an incision, he succeeded in drawing off the contents of the sac, which were partly gelatinous, partly pultaceous, and very considerable in quantity. He then brought the sides of the wound together, and secured them by suture, leaving an aperture, however, through which a discharge from the cyst continued to pass for some time. The opening finally closed, and the woman was *completely cured*, living fourteen years after, without any return of the tumour.

Archives Générales de Médecine, Vol. 58, p. 362.—A case of ovarian abscess is given by M. Löwenhardt, of Prenzlau, in which he evacuated the contents of the ovary through an incision in the abdominal parietes. For about two months the matter continued to drain away, *gradually decreasing in quantity*. At the end of this time the tumour had quite disappeared, the discharge ceased, and the opening closed. He says—"*La guerison etait complete.*"

Archives Générales de Médecine, Vol. 47, p. 354.—A case is recorded, (extracted from the *American Journal*, February, 1838,) in which Mr. Mussey, in attempting to extirpate a very large ovarian tumour was prevented doing so by numerous and extensive adhesions. He was obliged to have recourse merely to making a small incision into the tumour, through which its contents were drawn off. He kept up the opening by means of a tent. A clear liquid came away for several days; it then became *purulent, gradually diminishing in quantity for three weeks; when it closed, the tumour had disappeared.* A year after the woman was quite free from any return, and was delivered of her fourteenth child.

Archives Générales de Médecine, Vol. 50, p. 487.—A case is quoted of an operation by Mr. Arnott, of the Middlesex Hospital, in which he punctured the vagina, and a discharge from the cyst continued for *sixty-four days*, when a *complete cure was effected*, and the opening in the vagina perfectly closed.

The Editor in his remarks alludes to another case, *similar in its nature and results* to the one above mentioned, as having been published in the *Revue Médicale* by M. Recamier.

Archives Générales de Médecine, Vol. 31, p. 427.—This is an account of an operation for extirpation of ovarian tumour, attempted by Dr. Ehrhartstein, in which from an aperture in the external wound serum continued to drain for some time, which afterwards changed into a milky fluid, and did not disappear till the ninth week after the operation, when the wound cicatrised, *and the patient was cured.*

Archives Générales de Medecine, Vol. 20, p. 92.—A case is given by Dr. Dieffenbach, of Berlin, where the adhesions were such that he merely punctured the tumour after incision; a sanious matter continued to discharge itself through the wound for some time after, *and the patient ultimately recovered.*

Provincial Medical and Surgical Journal, Vol. 3, p. 593.—Mr. Bainbrigge's operation for ovarian dropsy. In this case an incision was made through the abdominal parietes into the sac; the contents (twenty-five pints of sero-sanguineous fluid,) were evacuated; a plug of lint was inserted to prevent union of the edges of the wound, by means of which a suppurative discharge was set up from the interior of the cyst, which was followed by its obliteration without a single bad symptom, and by a *permanent cure.*

NINETEEN CASES OF OVARIAN DISEASE, TREATED BY NATURE, ON THE PRINCIPLE WHICH MR. BAINBRIGGE HAS ADOPTED.

London Medical Gazette, Vol. 16, p. 643.—Dr. Ramsbotham relates a case of ovarian dropsy, discharged through an opening made by nature at the umbilicus; *the tumour disappeard.* The patient lived eight years after, and had *no return* of it. He also mentions a *similar case* of Dr. Mead's.

London Medical Gazette, Vol. 24, p. 966.—Dr. Henry Davies gives a case of ovarian tumour in which the integuments burst at the umbilicus, and discharged a thick red fluid, which gave great relief. The discharge continued for *seven years, during which the general health was good*; it then closed. Two years after she died of apoplexy.

London Medical Gazette, Vol. 25, p. 396.—A case of ovarian dropsy, bursting at the umbilicus, is related by Mr. Douglas, of Glasgow. The woman died two months after of peritonitis. From the particulars of this case, there does not appear any reason for connecting the operation and the subsequent discharge with the peritonitis.

Lancet, Vol. 2, 1839-40, p. 12.—Dr. Ingleby relates a case of ulceration through the abdominal parietes, through which an ovarian cyst emptied itself. There was a discharge for some time through the opening, followed by a *permanent cure.*

London Medical Gazette, Vol. 35, p. 303.—A case is given of diminution of the cyst, by a spontaneous opening into the abdomen at the navel, which discharged purulent lymph, and relieved the patient in a *permanent manner.* By Dr. Lambrecht.

Medical Times, Vol. 13, p. 262,—A case of *permanent cure* of ovarian dropsy is related as having taken place, after a spontaneous opening at the umbilicus, followed by a discharge of the contents of the sac, and formation of a fistulous passage, which subsequently closed.

Dublin Quarterly Journal, Vol. 1, p. 519.—It is stated that Dr. Montgomery has seen three cases in which ovarian cysts discharged their contents through the parietes of the abdomen. He does not state what the final results were; but had they been unfavourable or fatal, they would no doubt have been mentioned. A similar case is also alluded to, as being at the time (January 6th, 1843,) in Dr. Stevens's Hospital.

Edinburgh Medical and Surgical Journal, Vol. 2, p. 180.—A case by Mr. Anderson is given, in which a spontaneous opening took place at the umbilicus.

There was a discharge from the cyst which lasted *nine months, during which the tumour had gradually disappeared;* she then died, as it would appear, from general cachexy, under which she had laboured long previous to the opening being formed. The state of this patient's health a year before the operation was such, as under any circumstances, to render it improbable that she would live more than a few months.

London Medical Gazette, Vol. 8, p. 291.—A case is given of discharge of the contents of an ovarian sac through a spontaneous opening in the vagina, which ulcerated, and no doubt allowed any new formed secretion gradually to escape. The consequence was *almost complete disappearance of the tumour.* By Dr. Elliotson.

London Medical Gazette, Vol. 31, p. 572.—Dr. Waters gives a case of periodical return of an ovarian tumour and its entire disappearance two or three times after a copious discharge of a thick, yellowish, ropy fluid, viâ *recti et vaginæ.* After the last discharge no return of the tumour had taken place, and the patient's health was in a satisfactory state.

Lancet, Vol. 2, 1839-40, p. 12.—Dr. Ingleby gives a *case of cure* of ovarian dropsy, consequent on ulceration into the bladder, and permanent discharge per urethram, for upwards of a year, of albuminous fluid, shreds of coagulable lymph, and hydatids.

Lancet, Vol. 2, 1839-40.—Dr. Ingleby gives a case of rupture of ovarian cyst into the intestinal canal, as evinced by the vomiting of the contents mixed with fæcal matter, which he describes as lasting for some days, *and followed by a cure.*

Lancet, Vol. 2, 1842 43, p. 422.—A case of spontaneous *permanent cure* of ovarian dropsy, by a discharge from the cyst per vaginam, of several days' duration.

Medico-Chirurgical Review, Vol. 24, p. 206.—Gives *three cases of cure* by accidental rupture of a cyst into the vagina, and discharge through that opening; there can be no doubt that the discharge was continuous for a longer or shorter period.

Many more cases of the above description might be adduced if necessary, for the further elucidation of this very interesting mode in which nature operates successfully for the cure of this formidable disease.

With respect to the ACCIDENTAL CASES to which I have alluded, it appears to me that many *cures* have resulted from the bursting of the cyst into some portion of the intestines, or the bladder, as well as into the peritoneal cavity, under which circumstances a discharge of the fluid takes place, continuing for a longer or shorter period, and thus terminating as in the cases above detailed, in a more or less *permanent cure.* Instances of this kind are by no means rare. As to those cases where an accidental external opening has been made into the cyst through the parietes of the abdomen, as in the well-known case of the goring by a bull, &c. &c., a *permanent cure* has also been effected on similar principles.

The foregoing abstract professes to do no more than give a sufficient number of cases to exemplify the principle of the operation in question, and justify the conclusion I have arrived at. It is worth mentioning that the farther I extended my search the more I became convinced that this operation has been regarded either with *needless alarm* or *culpable indifference.* In presenting these as cases in point, it is to be observed, that with the exception of the first three on the list, it does not appear that the surgeons contemplated or understood the *rationale* of the operation. In their descriptions they seem to overlook the main fact, or mention it in a way to show they attach little or no value to it. Hence some of the cases must have laboured under serious disadvantages arising from careless or injudicious after-treatment, or from the non-employment of subsidiary means, calculated to promote a successful issue of the operation. The cases are, however, not the less on that account to be received in evidence, but rather the more, and I have no doubt that many of the cases on record in which the cure has been ascribed to different causes, or not attempted to be accounted for unless on some vague general principle, would, if more circumstantially detailed, exhibit the particular characteristic feature of the examples I have collected.

My list more than bears me out in the *ratio* I originally laid down, and even the two deaths may be accounted for, as indeed they were, by circumstances totally independent of the open state of the ovarian cyst or the discharge. It may be said that more extensive research would furnish many cases in which death has occurred, either during a discharge so superinduced and maintained, or after its cessation. I much doubt whether *many* such could be adduced—I have not been able to find them. Still I admit a few might be met with, but they cannot be considered as applicable unless it can be shown that the fatal issue might be fairly attributed to the discharge so established and circumstanced; and even could this be demonstrated, I feel confident it would not disturb my *ratio*, as a counterbalancing proportion of successful cases would also be discoverable.

Among the numerous writers on ovarian disease, such as Morgagni, Cruveilhier, Delpech, Lizars, &c. &c., few seem to have regarded this operation favourably. They either magnify its dangers or underrate its value. The cases they adduce in evidence against it do not apply. Instead of judiciously aiding nature in her friendly efforts, they interfere with, and obstruct her by means of stimulating injections or irritating substances, such as *canulas, leaden tubes, bougies, &c.*, left in the wound—a wound which, of all others, requires to be managed with the utmost delicacy and caution. What can be more contrary to the true principles of surgery, and what other than disastrous or negative results could be expected to follow such

practice? Cases treated in this way I exclude from the category. The *errors of art* must not be placed to the account of the *operations of nature*. Dr. Bright is one of those few authors who seems to have formed correct views on the subject, though not perhaps to have thoroughly appreciated its importance. He expresses himself to the effect that in some cases the wound does not close, and that suppuration continues for months or years, and that such an occurrence so far from being fatal, *prolongs existence*. This judicious observer no doubt speaks from experience.

I have again to thank your correspondent, INQUIRER, for the present opportunity, which I gladly embrace, to make a few additional remarks on my own case, suggested by a re-consideration of its details. On making the incision, I should not in any future case consider it advisable to remove a large portion of the cyst, *with a view to diminish the extent of the secreting surface*. I should leave its gradual contraction to nature. In all the cases above given, where nature operated, the sac remained entire, and no bad symptoms followed. There is besides an objection to it where the sac is *free from adhesions*. By removing a considerable portion of a large cyst, I should have a wound of many inches in extent to bring into adaptation with one of inferior dimensions. A *puckering* of the edges of the cyst would inevitably follow. These *puckerings* could not be applied to the lips of the external wound; union therefore might be incomplete, thereby endangering protrusion of the abdominal viscera, and an escape of matter into the peritoneal cavity,—two very serious accidents which must be most carefully guarded against. I should simply remove as much of the sac as would leave the opening in it as nearly as possible corresponding with that of the external wound, and unite the lips of both, accurately and smoothly, by the uninterrupted suture. I am now alluding to sacs free from adhesions at the point of operation.

But when the sac is adherent at this point, all this labour and difficulty are saved. Here it is worthy of note, that the very circumstance which most seriously complicates the *major* and *minor* operations—so called—viz., the existence of adhesions which must be torn or cut through, is not a source of danger, but rather a *great advantage* for the successful accomplishment of the present plan; and indeed could it be possibly ascertained by auscultation or otherwise, that adhesion to the walls of the abdomen existed at any particular point, I should select *that point* for my incision, provided it presented no extraordinary anatomical obstacle.

After the operation all that is required is to introduce a tent of lint into the wound to prevent its closure, foment the whole of the abdomen with warm water, and keep the patient very quiet for a few days, allowing no escape of the fluid except at the time of dressing. The plug should be kept in firmly by means of a compress and bandage, and removed once or oftener in the twenty-four hours, according to the amount of secretion.

In my case, *after the suppurative process* had been established, the quantity of matter being for some time considerable, I placed the patient on a prone couch to allow of its gravitation towards the external opening and its gradual escape. More or less inflammatory action must be expected to ensue after the operation; this should be allowed to subside, and no risk incurred of its increase by leaving canulas in the wound, as was done in cases operated upon with no result by Mr. C. A. Key. The mere introduction of pieces of leather, softened by steeping in oil, as substitutes for the lint plug, produced so much irritation during the chronic discharge in my case that I was compelled to have recourse to leeches and fomentations.

With respect to the cases in which nature herself performed the operation, I cannot help observing, how wonderful and beautiful are her resources under such extremities! and how *long and vainly* has she laboured to indicate to us a safe and simple mode of treating ovarian dropsy! After hundreds of experiments, and ages of experience, we cannot, I feel assured, act wiser or better, even in the present day, than simply to watch her movements, and *imitate her example*. Observe how cautiously she makes her external opening, and instead of violating the system by such a sweeping act as that of the major or minor operation, she almost imperceptibly sets up a new action in the cyst, adapts the treatment to circumstances, and gradually obliterates the cavity.

I trust, Sir, that I shall not be considered as needlessly obtruding myself on the notice of the profession by bringing this case so prominently forward, and entering so minutely into its details. I have been influenced simply by a wish, and animated by a hope, that others may be induced to try a similar method, and reap a similar reward. I shall be glad to see the subject elucidated by other more gifted individuals. The enquiries of your correspondent seem so reasonable, and the operation itself of such vast importance to the interests of suffering humanity, that without loss of time, and at considerable personal inconvenience, I have endeavoured to reply to the best of my ability, and indicate more clearly than at first, what appears to me, the best and safest course to be persued in the practice of OVARIOTOMY.

I remain, Sir,

Your very obedient servant,

W. H. BAINBRIGGE.

Liverpool, January 1, 1847.

PATHOLOGICAL REMARKS ON A CASE OF HEPATITIS RESULTING IN ABSCESS.

By Edmund Boult, Esq., Fellow of the Royal College of Surgeons of England, H. P. Bengal Medical Service, Assistant Surgeon to the Eye Infirmary, Bath.

(Read at the December Meeting of the Bath Pathological Society.)

J. B. a woman, aged 53, of a very full habit of body, and accustomed to live freely, applied to me on the 18th of October, 1845, suffering from congestive dyspepsia. She was generally speaking healthy, but had suffered in her lifetime from inflammatory disease in the chest. She was freely purged with mercurials and saline aperients; low diet was enjoined, and in a few days she was well again; but on the 4th of November, without any assignable cause, (except perhaps an excess of diet, which was not acknowledged,) she was suddenly seized with rigors, followed by the usual symptoms denoting acute inflammation of the liver. The pain was so very acute and so sensibly increased by the slightest touch or pressure, as to lead to the supposition that the peritoneal coat of the right lobe was principally engaged. From the first onset of the disease the urine was completely loaded with lithate of ammonia, so much so as for the first few hours after it was passed, to have the appearance of a brick-red liquor, without any sediment, but afterwards the deposit was thrown down and the fluid assumed a yellowish tinge.

The disease was met very actively, with the usual treatment, which it is not my purpose to dwell upon. I will just observe, that she was freely bled, locally and from the arm, afterwards blistered, freely purged, her system brought rapidly under the influence of mercury, and a strict antiphlogistic regimen enforced; by these means the pain was mitigated, but the inflammation instead of subsiding altogether as was desired, gradually assumed a sub-acute character, and was not to be overcome.

Under these circumstances, abscess was the result naturally to be expected, and accordingly about the beginning of January, 1846, she was again seized with rigors, followed by pulsation or throbbing in the hypochondrium. By the 10th of the same month, the side was tumefied, and fluctuation was readily perceived. The patient, however, was much exhausted; her pulse was 96. On the 11th it had risen to 120, was hard and jerking, betraying in itself the existence of pus, pent up in the system. On the 12th she was troubled with constant bilious vomiting; her countenance was anxious, and it appeared that if she were not relieved in a few hours, death must be the inevitable result. Still she had naturally a good constitution, and there was reason to think, that if freed from accumulating pus, she might rally. Her pulse this day was not to be counted, as she had been hurried getting up to stool; the evacuation being of normal character. I must not omit to mention, that at this time, since the setting in of suppuration, the urine had regained a healthy appearance, and was free from all deposit.

Under these circumstances, with concurrent valued advice,* selecting the softest and most depending situation, on the outer side of the hypochondrium, I passed a trocar obliquely upwards and inwards into the cavity of the abscess, and evacuated nine ounces (by weight,) of pus, mingled with bile, and then placed a small tent of lint in the wound.

The patient was faint, and suffered much from bilious vomiting, but on the whole was relieved. She slept and took nourishment, and in the evening her pulse was 100, soft and equable.

On the 13th I removed the plug, as no pus had escaped through it, and took away five ounces more of similar looking pus to that evacuated the previous day.

The patient still suffered for some days from bilious vomiting, which was very troublesome to manage. The abscess continued to discharge freely and the fluid evacuated seemed to consist of as much bile as pus, and the urine again threw down large deposits of the lithate of ammonia. Once or twice I thought it contained bile, but this was not tested.

The sinus was very difficult to keep open, the external orifice getting frequently glued up, but as soon as any quantity of pus re-accumulated, she became evidently feverish, and altogether worse. However, she gradually improved, and on the 12th of February, a month after the puncturing, I explored the sinus, and found it three inches and a half deep; but as far as I could detect, the cavity of the abscess was nearly obliterated. On the 16th the discharge had almost ceased, and I allowed the orifice to remain closed, in hopes that the sinus would become sound throughout its extent. On the 22nd, deposits ceased in the urine, though on the 25th, it was again loaded.

The patient was now able to move into an adjoining room, though her pulse kept at 105, and she continually complained of cold, and had nearly lost the use of her limbs from paralysis.

Shortly after this she went into the country, and was not under my eye. There I learned that some degree of pain recurred in the side, and it became again tumified, the sinus re-opened and a similar evacuation, as regards quantity and quality, was discharged as on the former occasion.

She returned home after an absence of fifteen weeks. When I examined her, I found the wound still wept a little serum, her pulse was 100, and she was nearly hemiplegic, but her appetite was good and tongue clean. I gave her very little medicine and she began to improve. In August her pulse came down to 84; her side was free from all tumour or tenderness; the sinus was quite closed; her general health much improved; and she was recovering the use of her limbs. When I saw her a few weeks ago, she was enjoying a very fair state of health. She has again returned to the country and I was informed a few days since, that she continues to regain more of her original good health, and has discarded her crutches; but I must not omit to mention, that occasionally, slight tumidity recurs in the side, and a fluid resembling pure serum

* My friends Drs. Bowie and Fergusson, and Mr. Underhay, were so good as to see this case with me, and agreed as to the necessity of puncturing the abscess.

oozes from the sinus in sufficient quantity to moisten her clothes; in other respects she has nothing to complain of.

Having briefly sketched the history of this case, I proceed to make a few pathological remarks on the disease. When inflammation of the liver of an acute or sub-acute character has existed for any length of time, we know that suppuration is not an infrequent result, and the diagnosis of abscess, generally speaking, is not difficult; except perhaps in that form which is described as occurring most frequently in scrofulous constitutions, where a number of small abscesses, about the size of a filbert each, are scattered throughout the substance of the organ; and it may occur, that in cases where fluctuation is readily perceived the pus may be contained in two or more distinct sacs not communicating with each other. Such a circumstance would occasion serious embarassment if relief were attempted by external puncture.

In the present case suppuration was ushered in with rigors, though they are by no means its invariable concomitants. In those cases where the disease progreses insidiously, or where pus is laid down secondarily in connection with dysenteric disease, rigors are generally absent. This circumstance tends to make the exact diagnosis more difficult. I have frequently, in examining the bodies of European soldiers of Her Majesty's Regiments in Bengal, been surprised to find immense collections of pus in livers, where its presence had not been suspected, though in relation to this subject, the late Mr. Twining, a very high authority, says,—"I believe there are always symptoms, which though obscure, are always sufficient to point out the disease." (Diseases of Bengal, Vol. I., p. 29.)

The patient's pulse was quick, small, and jerking, indicating pus being pent up in the system. Increased tumefaction and a sense of fluctuation were soon perceptible in the hypochondrium, and these symptoms are always to be expected when the disease is situated superficially. It is only in the "deep central abscess" that obscurity is likely to occur.

The mere circumstance of pus being formed in the substance of the liver, even with a tendency to travel outwards, affords no guarantee that adhesive inflammation will occur between the opposed layers of the peritoneum; but in this case there was great reason to suppose, from the great pain and tenderness at the onset, that the peritoneal coat was primarily engaged, and this led me to infer that no danger of extravasation into the cavity of the membrane would occur, if an external opening were made, to give exit to the confined pus. The abscess was clearly situated in the superficial portion of the right lobe, and Nature was endeavouring to affect her own cure by tending to a discharge externally; but it was evident that the patient's constitution could *not* afford to wait the result of Nature's own operations, and it became necessary to assist her, otherwise in a few hours death would have occurred from exhaustion; or it appeared possible that the abscess might burst into the peritoneum,—a result not by any means so infrequent as some have supposed, especially in India, where the patients usually die within a period varying from a few hours to a few days.

Assuming Dr. George Budd's opinion to be correct, that the prognosis of hepatic abscess is more unfavourable, generally speaking, when it is discharged immediately externally through the abdominal walls than by any other channel, it is very important to mark what are those conditions which seem most likely to promise a favourable result; and amongst the most evident is the circumstance of the abscess being situated superficially, because then there is most likely to be a less amount of disorganization, and then there is by far the greater probability of adhesions being formed between the layers of the peritoneum, the want of which is a very certain drawback to the success of any operation, and I am doubtful whether Dr. Graves' or any other method offers any certainty of producing such adhesions.

The quantity of pus evacuated was not great; nine ounces, by weight, seemed to empty the sac. We know that the amount of softening and sero-purulent infiltration with which abscess commences, is proportioned to the intensity of the engorgement and subsequent inflammation; and it is evident that they must equally depend upon the amount of structure engaged. Thus, I presume, only a portion of the organ was inflamed in this instance.

The pus discharged was clearly mingled with a large proportion of bile; and I would ask,—was this bile secreted by the walls of the abscess, or was it infiltrated through them from the surrounding parenchyma? It might be supposed that the gall-bladder was injured; but in another case, where large quantities of bile were discharged externally, and the patient died, the gall-bladder was found intact. Perhaps the more probable supposition is, that a large duct was opened by the process of ulceration, and that it refused to take on a reparative action, and so allowed the bile to escape.

The operation was succeded by vomiting. On this symptom I will remark presently.

Long after the patient had rallied from the primary attack the pulse continued high; and although she ate and drank, and slept well, and the side was free from all tenderness, still there can be no doubt that inflammation of a low sub-acute character was going on. Suppuration is a result which relieves and checks inflammatory action, but by no means vanquishes it; and this low inflammation ultimately produced a secondary formation of pus in the sac of the abscess, at which time the patient was not under my eye; but there is great reason to suppose that the original inflammation had never been entirely subdued, and it existed, I believe, without producing pain. The liver itself is not highly susceptible of pain, and I

apprehend that the very painful symptoms in hepatitis are mainly dependent upon the tension, inflammation, or sympathy of its serous investment.

The character of the urine next demands an observation or two. From the first attack of the disease the urine was marked by large deposits of lithate of ammonia, distinguished by a great amount of colouring matter being developed with it, so much so as to give it the appearance of that very scarce kind, which is described as being permanently *red*, and which throws down no deposit. Its specific gravity was rather low, 1.014, at a temperature of 60°, and it contained no albumen.

Deposits of lithate of ammonia are very common in hepatic disease, and I need no apology for quoting Dr. Prout's views on the subject. He says "the lithate of ammonia is not only supposed to be derived from imperfectly assimilated chyle, but also from the deranged secondary assimilation of the albuminous textures of the body." (Stomach and Renal Diseases, p. 203.) He considers that the liver not only performs a *negative* or *excretory* function, but also a *positive* or assimilating power over the oleaginous tissues. The following are his general inferences on this subject:—

"First, the liver is the organ by which the blood is depurated of unassimilated and superfluous oleaginous matters, as well as of those portions of the blood deprived of its azote, of its saccharine constituents, and consequently of its vitality, during the primary assimilating processes. Secondly, the kidneys are the organs by which the blood is depurated of its unassimilated, superfluous, and effete albuminous principles, as well as of the mineral matters incidental to these principles which are otherwise derived. Thirdly, the neutral and alkalescent character of the bile, and the oxygenated and acidulous character of the urine, shew that the general characters of the actions going on in the liver and kidneys are opposed to each other;—in short, that the general action of the liver is of a negative, the general action of the kidneys of a positive, character; and that one of these important organs, antagonistically related to each other, cannot be deranged without deranging the other." (Op. cit., p. 569.) To this he adds a foot note—"This deduction may be stated more generally, thus:—The liver may be considered as the principal focus or *pole* of all the *negative*; the kidneys as the principal focus or *pole* of all the positive actions going on throughout the organic system."

During the continuance of certain hepatic and other diseases, the process of assimilation is interfered with, and lithates are largely eliminated by the kidneys. Now, in the present case, I have before remarked, that on the setting in of suppuration, all deposit ceased in the urine. How is this phenomena to be explained? I apprehend that during the progress of the disease the liver was in a state of intense engorgement, which completely interfered with the due performance of its normal functions. This engorgement was partially relieved by the pouring out of pus. The organ freed from an overpowering incubus, immediately resumed its proper office, and bile was secreted in an inordinate quantity, which was the cause of the troublesome vomiting already alluded to, and which was quite distinct from the vomiting of irritation which occurs where abscess is situated near the inferior surface of the organ. The kidneys then ceased to eliminate the abnormal quantity of lithate of ammonia, and the balance of secondary assimilation for the time was restored. After a while the engorgement again took place, the relief being temporary; the lithate was again thrown down in the urine, and continued with slight intermission until convalescence proved that the entire function of assimilation was satisfactorily performed. I regard this as interesting in a pathological point of view, and corroborative of Dr. Prout's hypothesis.

There is another point to which I must just refer, without at all entering into the question. The patient from the time the abscess was opened, complained continually of a sensation of chilliness, even whilst the surface of her body to the touch felt hot and dry. Now, this symptom may, I think, be taken with the paralytic affection, and be considered as arising from impaired nervous energy, consequent upon so severe an attack of disease in so important an organ. But on the other hand it may be that this symptom was connected with an interesting question. If the views of some authors be correct, we may enquire how far the function of combustion, the evolution of caloric, was interfered with by this lesion of the liver; but this rather belongs to physiology than pathology, and I shall not attempt to enter upon it now.

Lastly, the question may be asked,—What is the present condition of the organ?

The *post-mortem* examinations of individuals who have died several years after recovery from hepatic abscess, have discovered no remains of the disease, excepting sometimes the existence of adhesions between the opposed surfaces of the peritoneum, and I believe in most cases the sac is perfectly obliterated. How is this effected? In similar cases, abcesses have been found difficult to heal, and some practitioners have attempted to close them by exciting adhesive inflammation in the sides of the sac; but suppurating, like mucous, surfaces, do not readily take on inflammation of an adhesive character, and the attempt has usually failed. The process of obliteration is, I believe, accomplished gradually, as the abscess was formed. As in the latter case absorption increased around the primary softening and infiltration; so afterwards, new healthy parenchymatous structure is laid down, gradually lessening the area of the sac, until nothing but the walls remain; these are at last absorbed themselves, and the organ regains its original integrity of structure. Where the

peritoneum has been inflamed, as in the present case, doubtless adhesions will be formed, but Mr. Twining remarks, that it is surprising how seldom they do exist, even in cases where the abscess was situated superficially and tended towards an exit through the abdominal parietes. Have I a right, then, to suppose that the liver in this case has recovered its original integrity? The only suspicious circumstance which leads me to doubt at all, is the occurrence of the occasional tumidity and serous oozing; and yet I can hardly think that the sac is still in existence, and rather believe that the oozing may be derived from the remains of the sinus. Be this as it may, I do not feel inclined to attempt to decide the question by the introduction of a probe, but enjoining the woman to take the strictest care of herself as regards diet, and exposure to wet or cold, I leave the matter for time to elucidate.

Bath, December, 1846.

CASE OF AMPUTATION OF THE THIGH UNDER THE INFLUENCE OF ÆTHER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

As the medical profession at this moment must feel deeply interested in the late discovery made by our Transatlantic friends, of the inhalation of æther producing that state of narcotism which renders persons insensible to the pain arising from surgical operations, I offer no apology for sending you the following brief account of an experiment as to its effect, which came under my own observation yesterday. My partner, Mr. Coleman, having occasion to perform amputation of the thigh upon a young woman of a highly nervous temperament, and who dreaded the pain of the operation exceedingly, we deemed it a favourable opportunity to test the efficacy of this new discovery. By the kind assistance of Mr. Julion, a talented young chemist, we prepared the necessary apparatus to conduct the experiment. The patient being brought to the edge of the bed, the tourniquet applied, and everything prepared to commence amputation, she began to inhale the æther, which produced a good deal of coughing, and it was with some difficulty we prevailed upon her to persevere, which she at length did;—not, however, in a very satisfactory manner, drawing only short inspirations, and then removing the tube from her mouth. After using it for the space of three or four minutes, her teeth became fixed, her eyes closed, and she sank back into the arms of an attendant, as if in a state of *complete intoxication*. Mr. Coleman now siezed this favourable moment, and very adroitly and expeditiously performed the flap operation. The patient struggled with her hands, and cried out for her mother, (who had been dead some years.) The sound limb was not held, nor did she move it, but frequently said "she would not have her leg cut off then;" indeed it was quite evident she was not aware of the operation being performed; for after the stump was dressed, and she was comfortably placed in bed, she said "it was not off, for her foot was asleep," and begged of some of us to rub it. On enquiring of her, some hours after the operation, what she had felt, she said "she thought she had been in a dream, and that we had hurt her leg, to see if she could bear the operation, which was to be performed the next day." She had no recollection of any cutting pain, nor could she tell the kind of pain she had suffered, but thought she remembered "hearing the bone sawed."

The narcotic effect of the æther soon subsided; for in putting in some sutures to bring the edges of the stump together, the passing of the needle through the skin, produced cries of the *most agonizing pain*, though her mind was not sufficiently restored to consciousness, to be aware of what was going on.

The result of this trial I cannot but think highly encouraging; and fully believe, that if the inhalation had been more perfectly accomplished, the state of insensibility would have been most complete. So satisfied am I, that we now possess a means of narcotizing pain, that I shall not hesitate to adopt it in any case where a painful surgical operation has to be undergone, taking care in future to render my patient thoroughly conversant with the mechanical process of inhalation, previously to the use of the æther.

I remain, Sir,
Your obedient servant,
GEORGE EDWARDS.

Wolverhampton, Jan. 2, 1847.

P.S. January 3rd. Our patient is going on very favourably, and still persists she had a dream during the operation.

Hospital Reports.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF WILLIAM SANDS COX, ESQ., AT THE QUEEN'S HOSPITAL, BIRMINGHAM.

By PETER HINCKES BIRD, one of the Resident Medical Officers.

CASE XVII.

FRACTURE OF THE BASE OF THE SKULL.

William Stock, aged 41, admitted July 11th into the Queen's Hospital, at half-past four o'clock p.m. He is a guard upon the Gloucester Railway, and is a very tall powerful man. It is stated that while the train from Gloucester was going along at full speed, he was standing with his back to the engine, on some luggage on the top of one of the carriages, and on going under an archway his head struck against the arch with great force. He immediately fell down insensible. He lost a considerable quantity of blood from a wound of the scalp before his admission.

When admitted he was in a complete state of coma, with stertorous breathing; dilated pupils, insensible to the stimulus of light; total loss of sensibility, and of power over the voluntary muscles; extremities cold,

the feet more so than the arms; pulse weak, very slow. about 30; considerable discharge of dark blood from the right ear. On examination there was found a lacerated wound of about four inches extent, situated over the junction of the two parietal bones at the sagittal suture; careful examination was made by the finger and by a probe, but no fracture or depression of bone was discovered under the wound on the scalp. There was considerable bleeding from the posterior temporal artery, which was easily arrested by a compress. The wound was lightly dressed and the patient put to bed.

He gradually got worse, without any re-action taking place, and expired at a quarter past five p.m., just three quarters of an hour after his admission.

The *post-mortem* examination was made the following morning. There was found extensive extravasation of dark coloured blood under the wound for some distance; in one place under the wound a small portion of the pericranium was detached. On taking off the calvarium the brain was found gorged with blood; the meshes of the arachnoid were plentifully filled with dark blood; serous fluid was also found in the ventricles. There was no fracture of the inner table under the seat of the wound. On removing the brain, however, an extensive comminuted fracture of the occipital bone was discovered, commencing on each side above the groove for the lateral sinus; that on the left side crossing the spine for the falx cerebelli, and extending into the lateral sinus of the right side; that on the right side crossing the fracture of the left side, and extending into the border which articulates with the petrous portion of the temporal bone. One portion of the fracture extended into the foramen magnum, the portions of bone forming which were very loose. One large portion of bone included within the lines of these fractures, was quite loose, so that it might be easily removed. A large quantity of black blood was effused at the base of the brain, and between the theca vertebralis and spinal cord. The cribriform plate of the ethmoid bone was also shattered.

Fractures at the base of the skull are extremely dangerous, because they are generally attended with extensive extravasation, or are followed by inflammation of the brain, in consequence of the great violence of the injury; so that they are generally regarded as inevitably fatal.

According to Sir Astley Cooper fractures at the base of the skull are produced from falls from a great height on the summit of the head; but they are also produced by violent blows on the vertex, and by heavy falls on the feet or tuberosities of the ischium. When it is produced by falls from a great height on the summit of the head, the whole weight of the body is received on the foramen magnum, and on the cuneiform process of the os occipitis, and in many instances, the consequence is a transverse fracture through the foramen magnum, the cuneiform process, and part of the temporal bone. The dura mater is generally lacerated and the substance of the lower surface of the brain itself wounded, and blood consequently effused at the base of the brain, and in some cases, caused by a greater degree of violence, not merely in this situation but in others.

This accident seems to have been caused by intense violence applied to the vertex; the consequence was a most extensive comminuted fracture of the occipital bone, accompanied with the symptoms of compression.

There is no symptom by which we can confidently diagnose fracture of the base of the skull. A discharge of blood from the ears is said to be a diagnostic symptom; in this case it was present on the right side, into the lateral sinus of which the fracture had extended itself. Sir Benjamin Brodie relates a case which was attended with hæmorrhage from the ear, where the source of the blood was found to be after death the lacerated cavernous sinus. Hæmorrhage from the ears, however, comes on sometimes from slight injuries not at all affecting the cranium or its contents; while other cases are met with, where, on dissection, extensive fractures are found of the petrous portion of the temporal bone, and of the sphenoid and ethmoid bones, though no bleeding at all had occurred from the ears, nose, or mouth. It is supposed that the deafness which sometimes remains during life, in rare instances of recovery, is the result of the discharge of blood into each meatus auditorius. A *post-mortem* examination is therefore the most convincing proof of death from fracture of the base of the skull.

PROVINCIAL
Medical & Surgical Journal.
WEDNESDAY, JANUARY 13, 1847.

The Report of the Committee appointed at Norwich to take into consideration the publications of the Association with a view to their improvement, and the resolutions of the Central Council adopted in consequence, will have made known the changes intended to be introduced into the Journal. We have now only to state that every effort will be made to carry out these recommendations, and to render the Journal under its increased size, a record of the progress of Medical Science and Practice, giving special prominence to the provincial districts and to all subjects of interest to, or connected with, the Provincial Association.

In the present number the necessity of devoting a considerable space to the Report of the Committee, to the Memorial of the College of Physicians, and to the new Registration Bill, has necessarily led to the deferring of some communications belonging to the departments of Hospital Reports and Proceedings of Societies, (both of which it is intended should occupy a prominent place,) and to the omission of the General Retrospect; but while every subject

of interest to the general welfare of the profession, and the *status* of its members, will be at all times carefully attended to, it is to be desired that the *Provincial Journal* should be mainly occupied with information of a scientific and practical nature, the recorded experience of the members of the Association, and others who may contribute to its pages. The increased size will be found to allow of more elaborate communications,—the longer interval of publication will admit of more care in the selection of the original articles and other matters,—while the advantages arising from the facility of transmission by the post to all parts of the kingdom are still retained, and the members of the Association and subscribers to the Journal can receive it without trouble or delay within a few hours of its publication.

The pressure of other matter precludes any extended remarks, and we prefer that the Journal should carry with it its own recommendation; but we trust that when the arrangements are completed it will be found not only enlarged and improved, but altogether such as the members of the Association will estimate and approve.

Proceedings of Societies.

SHEFFIELD MEDICAL SOCIETY.

Sixth Session.—Sixth meeting, December 10th, 1846.

The President, Mr. TURTON, in the Chair.

Mr. Jackson exhibited drawings of a patient's legs with necrosis of the tibia, taken three years ago. He also exhibited the necrosed portions of bone lately removed by Mr. Beckitt.

ASCITES: HYDATIDS.

Dr. Branson exhibited a portion of fluid taken from the peritoneal cavity of a man aged 18. The fluid contained an immense number of hydatids, varying in size from that of a hen's egg to the most minute vesicle as seen under the microscope. The patient was under the care of Mr. Burman, of Wath, who had forwarded the fluid for exhibition, accompanied by the following history of the case:—

"Benjamin Downing, aged 18, first came under my care in December, 1839. He was then much emaciated, and had an enormously distended abdomen, which, on percussion, gave a perfectly distinct fluctuation. As he had taken large quantities of the usual medicines without benefit, I determined at once to tap him. Upon introducing the instrument, which was of the usual size, I was surprized to find that no fluid followed the withdrawal of the stilette; however, while I was still pondering upon the case, several small hydatids passed the canula, floating in a liquid strongly resembling, both in colour and consistence, the yolk of eggs. As I had fortunately with me a much larger instrument, which had been made for a particular case, I withdrew the smaller one and introduced it. The result was an immediate flow of fluid, mixed with an immense quantity of hydatids of various sizes, which continued till the end of the canula became obstructed by a larger cyst. This proved to be as large as a hen's egg, and I was compelled to rupture it by gently pressing against it with a female catheter; with which instrument I also succeeded in removing the empty cyst. In this tedious way I at least succeeded in emptying the peritoneal cavity, having abstracted fluid, hydatids, and ruptured cysts, amounting to upwards of twenty-four pounds in weight. Not a single bad symptom followed the operation; the poor fellow rapidly recovered, and I lost sight of him for upwards of five years, when I accidentally met on the road a fine tall muscular young man, who made himself known to me as the poor sickly boy upon whom I had operated at the time above mentioned. He had ever since that time been at very laborious work upon a railroad in Lancashire, and was then returning to resume that kind of labour, which he continued to do in perfect health, till about twelve weeks since, when after a severe cold the abdomen began to fill again rapidly. He came over from Lancashire and put himself under my care again, and last week I operated upon him, and removed about twenty-three pounds in weight of the same kind of mixture as I had done before, a portion of which I send you. The yellow colour is gone in a great measure, but you will find a number of transparent hydatids floating on the surface of the liquid, and many of the larger (broken) cysts at the bottom, which are thicker and opaque. In the more fluid part are seen under the microscope, a vast assemblage of minute vesicles, apparently hydatids in embryo, resembling in everything but their size the larger cysts. Since the operation the man is doing very well, and I hope will soon be able to resume his labours.

ASPHYXIA.

Mr. Law exhibited the liver, heart, and kidneys of an infirmary patient, aged 32, a married man, stout and well-formed a case-maker, who died of asphyxia, on the 26th of November, in the Infirmary, where he had been an in-patient six days. No satisfactory information was gathered respecting his habits, but it is believed that he had long been in the practice of drinking intoxicating liquors. There was ossification of the aortic valves, a condition which was sufficiently indicated during life by a loud bruit de soufflet accompanying the first beat, and heard best over the aortic valves. The liver was diminished, dense, granular, wrinkled, and of a yellow colour, presenting indeed a good example of the condition which has been termed "cirrhosis," but which term the exhibitor believed, is employed to designate several pathological changes of this organ. Although Dr. Baillie does not employ this term he has yet figured the disease; and he observes, "that it is commonly said to be scirrhus, but the morbid appearance is very different from the genuine scirrhus.

of the glands. It should rather be considered as a disease *sui generis*." Both Dr. Baillie and Dr. Marshall Hall, regard diminution as an essential element in the disease, and the latter adds, "it is uniformly attended by ascites but without icterus." In the case under consideration there were ascites and anarsarca, but no icterus. The kidneys were in the last stage of granular degeneration. It may perhaps be worth while to remark that this patient was considered on his admission into the Infirmary, to be labouring hopelessly under acute renal dropsy. The heart-disease was regarded as chronic, and the liver affection was not and indeed could not have been detected on account of the ascites. The urine was examined the day after admission, and again the day before he died. On the first occasion its specific gravity was 1.012, on the second 1.015; it was coagulable on neither of these occasions. Of the urine in the earlier stages of the disease, nothing is known. Perhaps it is not quite obvious how far coagulable urine is connected with that structural lesion called Bright's disease.

RUPTURE OF THE POSTERIOR TIBIAL ARTERY; AMPUTATION: PHLEBITIS.

Mr. Micklethwait then related the following case:—A married woman, aged 51, was admitted into the Hospital in September, 1844. The whole of the back of the right leg from the popliteal space to the ankle was uniformly swollen, was red, painful, and tender; no pulsation or bruit could be detected over the swelling, which had existed nearly two months previous to her admission. At the end of a month the lower part of the leg was reduced to nearly its natural size, but in the situation of the belly of the gastrocnemius it continued as large as ever. During the next fortnight the leg increased in girth, and became generally softer; there was a well-marked sense of fluctuation between the heads of the gastrocnemius, and the pain had become much more severe, and in addition, there was an œdematous state of the dorsum of the foot. At the end of another month the countenance had become sallow and extremely haggard; the pain was even more severe, and there was a secretion of a yellowish green transparent fluid from the skin, which at this part was thickened and appeared irregularly roughened. In one place a small excrescence, soft, smooth, and shining, had appeared, and the outer and back part of the calf of the leg had also become of a purplish hue, with enlarged cutaneous veins, the swelling thus assuming an aspect of malignancy. The sense of fluctuation remained distinct. After a fornight's interval of comparative ease, a violent attack of pain recurred without apparent cause, and continued for some days in spite of frequent and large doses of morphia. As she was anxious for something more to be done, an incision was made into the tumour, when its contents proved to be coagulated blood. On passing the finger through the clot, florid arterial blood gushed out profusely; the tourniquet was tightened and immediate amputation determined upon.

On the tenth day after the operation she had a severe rigor, unattended by pain in any part, or by cough, but there was increased rapidity of the pulse, which was exceedingly small. There was more restlessness and uneasiness from position, the features became extremely pinched, emaciation increased, and there was complete loss of appetite. Notwithstanding the free administration of stimulants, the rigors continued, and the weakness increased. Slight cough came on unattended by pain even on deep inspiration; respiration became hurried and obstructed, the pulse extremely feeble, and she gradually sank.

On dissecting the leg, the gastrocnemius was found expanded tightly over a cyst. On removing the soleus, a cyst was exposed, formed apparently by the deep fascia of the leg. The cyst seemed girt from above downwards, along the inner third by a tight cord, which proved to be the posterior tibial artery, vein and nerve. The cavities of the two former were not obliterated, but impervious from pressure; the vessels curved outward and forward to join the popliteal above, and resumed their natural position below the cyst. On opening the vessels, their inner surface seemed healthy. There was a small longitudinal rent in the anterior wall of the posterior tibial artery, about three-quarters of an inch from its origin, communicating with the cyst. The interosseous ligament was forced forwards, so as to be convex anteriorly instead of flat, and the posterior surface of the tibia was denuded of its periosteum, and rough.

The body was examined sixteen hours after death; it was much emaciated. There was nothing abnormal in the appearance of the stump; the divided structures were already contracted and agglutinated by organized lymph. The artery seemed healthy and pervious to within an inch of the ligature; this part was filled by a clot not yet conical, for the end of the artery was not completely contracted. The vein was blocked up from the divided end to the point where the internal, iliac joins the external iliac vein; the divided end was perfectly contracted. On opening the vein, and passing upwards for about two inches and a half, the diminished vessel was completely filled by coagulum, and in one part of this, entirely within it, was a small collection of matter, about the size of a hempseed; the next three inches were filled by a dirty brownish-red mixture of blood and pus. Higher up the vein was filled by adherent coagulum, and in the substance of this, an inch and a half below Poupart's ligament, was another abscess as large as a cherry stone; the contents of this, as well as the other, were thick, whitish, unequivocal pus. The internal iliac vein was filled with free pus. The common iliac and vena cava were pervious and apparently healthy. The glands in the groin were enlarged, but healthy in structure. There were small deposits of pus under the mucous membrane of the os uteri and adjacent part of the vagina. The uterus was oblique, and one lateral ligament considerably shortened; the ovary and Fallopian tube of that side being firmly adherent by lymph. Several patches of acute inflammation, with deposits of light reddish-brown lymph, were found in the spleen, and in the centre of one patch there was semi-purulent fluid. The liver was healthy, except in one part of its upper surface, which presented an ecchy-

mosed appearance, but which really consisted of a number of small veins distended with blood in an arborescent form. In the upper lobe of the right lung, not the apex, two deposits about the size of nuts were found, of a yellowish-white friable matter, much resembling recently deposited lymph and pus. The lower lobe of the left lung gave evidence of previous pneumonia. There were no tubercles, nor was any disease found in the other organs.

Mr. Micklethwait mentioned two other fatal cases of phlebitis following amputation, and remarked that no allusion to this somewhat unusual termination is to be found in either the works of Sir Astley Cooper or Mr. Fergusson.

MR. WAKLEY'S MEDICAL REGISTRATION BILL OF 1847.

A BILL

For the Registration of Qualified Medical Practitioners, and for Amending the Law Relating to the Practice of Medicine in Great Britain and Ireland.

Preamble.—Whereas the laws relating to the Practice of Medicine in Great Britain and Ireland are numerous, complicated, and contradictory, and the public possesses no certain means of distinguishing between legally qualified physicians, surgeons, and apothecaries, and the mere pretenders to a knowledge of medicine and surgery, and it is desirable that the names and qualifications of the regularly educated practitioners in medicine should be duly registered by competent authority:

1. *Registrars to be appointed.*—Be it enacted, by the Queen's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, That one of Her Majesty's Principal Secretaries of State shall, within one month after the passing of this Act, nominate and appoint three fit and proper persons, being at the time of such appointment qualified to be registered under the provisions of this Act, to be the registrars for carrying this Act into execution, one such registrar to be called the "Medical Registrar for England," another, the "Medical Registrar for Ireland," and the third, the "Medical Registrar for Scotland," and that he shall also from time to time appoint such clerks and other officers as he, the said Secretary of State, shall deem necessary for the assistance of the said registrars in carrying into execution the provisions of this Act; and that the said Secretary of State may at his discretion remove any registrar or other person so appointed aforesaid; and that upon the death or resignation of as any such registrar or other clerk or officer as aforesaid, or other vacancy in either of the offices so filled, the said Secretary of State shall appoint other proper persons to be such registrars, clerks, and officers respectively; and there shall be paid to the said registrars, clerks, and messengers, out of any monies to be received by the said registrars by virtue of this Act, such salaries as shall be from time to time fixed and allowed by the Lord High Treasurer or the Commissioners of Her Majesty's Treasury, who may also allow such reasonable travelling expenses as may be incurred by any registrar, clerk, or messenger in the performance of his duties under this Act, and such other reasonable expenses for putting and carrying this Act into execution, as the said Lord High Treasurer or the Commissioners of Her Majesty's Treasury shall think fit.

2. *Monies to be paid to Medical Registration Fund of Great Britain.*—And be it enacted, that all monies received by the registrars aforesaid, in carrying this Act into execution, shall be paid by them into the Bank of England, at such times and in such a manner as the Secretary of State aforesaid shall direct, to the credit of the Lord High Treasurer, or the Commissioners of Her Majesty's Treasury, and in the name of the "Medical Registration Fund of Great Britain and Ireland."

3. *Registration of Names, &c., of Qualified Medical Practitioners.*—And be it enacted, that the several registrars shall, within thirty days after their appointment, and from time to time aftewards, register, according to the form in schedule (A) to this Act annexed, in books to be kept for that purpose, and without any fee whatsoever, the name and place of residence, together with a description of the legal qualification or qualifications, with the date or dates thereof, of every physician, surgeon, and apothecary who shall apply to be registered, and who, prior to the passing of this Act, shall have taken a degree in medicine in any English, Irish, or Scotch University, or who shall apply to be registered, and shall produce his diploma, certificate, or license, or other proof of his having obtained a diploma, certificate, or license to practise as a physician, surgeon, or apothecary, dated prior to the passing of this Act, and granted by any English, Irish, or Scotch University, College, or Society, or any corporation, sole or aggregate, in England, Ireland, or Scotland, legally entitled to grant the same; and also of every person who shall apply for the same, who was actually practising as an apothecary in England and Wales prior to the first day of August, one thousand eight hundred and fifteen, and who shall sign a declaration according to the form in schedule (B) to this Act annexed, and also of every surgeon and assistant surgeon of the army and navy, and in the service of the Honourable the East India Company, who shall apply for the same, and of every physician, surgeon, and apothecary, upon the payment of *Two pounds*, who, *after* the passing of this Act, shall take a degree in medicine as aforesaid, or produce a certificate, licence, or diploma as aforesaid, dated subsequently to the passing of this Act.

4. *Registrars to issue Annual Certificates to Registered Practitioners.*—And be it enacted, that the several registrars aforesaid shall issue a certificate, according

to the form in schedule (C) to this Act annexed, to every person who shall have been registered as aforesaid, and who shall apply for the same; and be it further enacted, that the said registrars shall issue such certificates for those parts of Great Britain and Ireland only for which they shall severally be appointed to act.

5. *Payment of Five Shillings for Certificate.*—And be it enacted, that every person shall, upon his application for such certificate, pay to the registrar a sum not exceeding *five shillings*, and such certificate shall bear date on the day on which the same shall be issued, and shall thence continue in force until the thirty-first day of December, one thousand eight hundred and forty———, and no longer; and the said registrars, on or before the fifteenth day of December, in every subsequent year, upon the application of any person who shall be then registered, shall issue such certificate to such person in like manner in all respects as aforesaid, subject to the payment of a sum not exceeding *five shillings* as aforesaid, which said certificate shall take effect on the first day of January then next ensuing, and shall continue in force during one year, and no longer.

6. *Registrar to keep a Record of Certificates.*—And be it enacted, that each of the said registrars shall duly record in a book an account of every certificate which he shall issue as aforesaid, and in the month of January in every year shall cause to be printed a correct register, arranged alphabetically, of the names of all persons to whom he shall have so issued certificates during the year then last past, according to the provisions of this Act, together with their places of abode, and a description of their legal qualification or qualifications, with the date or dates thereof, and such registers shall be respectively called, "The Medical Register for England," "The Medical Register for Ireland," and "The Medical Register for Scotland;" and a printed copy of the register for the time being, so published as aforesaid, shall be evidence in all courts, and before all justices of the peace and others, that the persons therein specified have obtained a certificate according to the provisions of this Act; and the absence of the name of any person from such printed copy shall be evidence, until the contrary be made to appear, that such person has not obtained a certificate according to this Act; and copies of such Medical Registers shall be furnished by the respective registrars to every person who shall apply for the same, upon the payment of a sum not exceeding *one shilling* for each copy.

7. *Persons accidentally omitted from Register may obtain Certificate on paying Twenty Shillings.*—And be it enacted, that if any person entitled by this Act to obtain a certificate as aforesaid, whose name and place of residence, and a correct description of whose qualification or qualifications, with the date or dates thereof, do not appear in such Medical Register as aforesaid, shall at any time apply for a certificate to any of the registrars aforesaid, and shall prove, to the satisfaction of such registrar, either that he is a person whose name, through neglect, accident, or mistake, has been omitted from the Medical Register then current, or that he purposes commencing or resuming practice, or changing his residence, before the first day of January in the ensuing year, every such applicant shall be entitled to obtain, from the registrar appointed for that part of the United Kingdom in which he resides, upon payment of twenty shillings, and sending his name and then place of residence, together with a description of his qualification or qualifications, with the date or dates thereof, a certificate as aforesaid, to continue in force until the thirty-first day of December then next ensuing.

8. *Repeal of Restrictions on Practice excepting such as are in this Act.*—And whereas it is just and expedient that all registered persons possessing certificates, in force as aforesaid, should be entitled to practise medicine in that part of the United Kingdom for which their certificates are issued; Be it therefore enacted, that so much of any Act or Charter granted before the passing of this Act as prohibits any person from practising medicine, physic, or surgery, in any place without such licence as is mentioned in any such Act or Charter respectively, or that imposes any restriction or penalty on the practise of medicine, physic, or surgery, further than is contained in this Act, shall be and the same is hereby repealed and annulled.

9. *Registered Persons entitled to Practise where Certificates are issued.*—And be it further enacted, that every person who shall be registered, and shall possess a certificate in form, according to the provisions of this Act, shall be entitled, without other licence than such registry and certificate, to practise medicine throughout that part of the United Kingdom in which his certificate was issued, and such person shall be deemed qualified to be appointed therein to any medical office in any public or other institution.

10. *Registered Practitioners entitled to Charge for Visits and Attendance.*—And be it enacted, that all persons who shall be registered and possess certificates according to the provisions of this Act, shall be entitled to demand and recover, in any court of law, with full costs of suit, reasonable charges for medical or surgical advice, visits, and attendance, rendered by them to their patients in any part of Great Britain and Ireland, without any other licence than such registry and certificates.

11. *None but Registered Persons or those in Practice before the passing of this Act to recover Charges.*—And be it enacted, that after the passing of this Act no person shall be entitled to recover any charge in any court of law for any medical or surgical advice, attendance, or operation, or for any medicine prescribed or administered by him, unless he shall prove upon the trial, either that he is registered under this Act, or that he was legally practising in the capacity in which he claims such charge before the passing of this Act.

12. *Repeal of Enactment requiring Five Years' Apprenticeship to an Apothecary. (Fifty-fifth George III., cap. 194, s. 15.)*—And whereas, by an Act passed in the fifty-fifth year of the reign of King

George the Third, entitled, "An Act for better regulating the Practice of Apothecaries throughout England and Wales," it was enacted "that no person shall be admitted to any examination for a certificate to practise as an apothecary unless he shall have served an apprenticeship of not less than five years to an apothecary;" and whereas the said enactment having been found to obstruct the efficient education of students in medicine, it is expedient that the same should be repealed; Be it therefore enacted, that so much of the said recited statute as requires the serving of such an apprenticeship as aforesaid shall be and the same is hereby repealed.

13. *Summary Penalty against Unregistered Practitioners. (Fifth George III., c. 194, s. 20.)*—And be it further enacted, that if any person shall, after the ——— day of ——— 18—, act or practise as a physician, surgeon, or apothecary, in any part of Great Britain and Ireland, without being duly registered according to the provisions of this Act, and without having a certificate as aforesaid in force at the time of his so practising or acting as a physician, surgeon, or apothecary, he shall, on conviction before any magistrate having jurisdiction in the county, city, or place where the offence was committed, forfeit and pay a sum not exceeding *five pounds*, nor less than *forty shillings*, for every such offence, to be recoverable within three months next after the commission of the said offence, under a warrant signed by the said magistrate, by distress and sale of the offender's goods and chattels.

14. *Penalty on Unregistered Persons far acting as Medical Officers.*—And be it enacted, that every person appointed after the passing of this Act to any medical or surgical office for which he is not qualified according to the provisions of this Act, and who shall act or practise in such office, shall for every such offence forfeit a sum not exceeding *five pounds*, nor less than *forty shillings*, to be recovered as is hereinafter described.

15. *Persons not possessing Certificates incapable of acting as Medical Officers in Public and other situations.*—And be it enacted, that from and after the first day of January one thousand eight hundred and forty —, no person who does not possess a certificate in force according to the provisions of this Act, shall be capable of holding any appointment in any part of Great Britain or Ireland in the capacity of a physician, surgeon, apothecary, or other medical officer in any hospital, infirmary, dispensary, lunatic or other asylum, lying-in hospital, gaol, penitentiary, house of correction, house of industry, parochial or union workhouse or poorhouse, parish union or other public establishment, body, or institution, or to any friendly or other society for affording mutual relief in sickness, infirmity, or old age; and the certificate or evidence of any person not possessing a certificate as aforesaid, given after the passing of this Act, shall not be received as the certificate or evidence of a physician, surgeon, or apothecary, or medical or surgical practitioner, in any court of law or equity, or in any matter or thing in which by law or custom the certificate or evidence of a physician, surgeon, apothecary, or medical or surgical practitioner, is or shall be required.

16. *Penalty for wilful falsification of the Record of Certificates by any Registrar.*—And be it enacted, that if any registrar under this Act shall wilfully make or cause to be made any falsification in any matters relating to any register, certificate, or record aforesaid, every such offender shall be deemed guilty of a misdemeanour; and shall, on conviction thereof, be sentenced to be imprisoned for any term not exceeding *six months*.

17. *Penalty for obtaining Certificate by False Representations.*—And be it enacted, that if any person shall wilfully procure or attempt to procure a certificate from any registrar, by making or producing, or causing to be made or produced, any false or fraudulent representation or declaration, either verbally or in writing, or shall by any false or fraudulent means whatsoever possess, obtain, use, or attempt to possess, obtain, or use, any certificate as aforesaid, every such person so offending, and every person aiding and assisting him therein, shall, upon being convicted thereof, be adjudged guilty of a misdemeanour in England and Ireland, and in Scotland of a crime and offence; and thereupon it shall be lawful for the court before whom such offender shall be tried and convicted, to sentence such offender to be imprisoned, with or without hard labour, for any period of time not exceeding three calendar months.

18. *Penalty for False Pretences of Qualification.*—And be it enacted, that every unregistered person who shall wilfully and falsely pretend to be, or take or use the name or title of a physician, doctor, bachelor of medicine, surgeon, or apothecary, or any name, title, addition, or description, implying that he is registered under this Act, or that he is recognised by law as a physician, or surgeon, or apothecary, or a practitioner in medicine or surgery, shall, on being convicted of every such offence before any magistrate having jurisdiction therein, pay a sum not exceeding *five pounds*, nor less than forty shillings, to be recoverable as is hereinafter described.

19. *How Penalties are to be recovered: if not paid, the offender may be committed.*—And be it enacted, that any justice of the peace acting in and for the county in which the offence has been committed, or any magistrate appointed by virtue of an Act passed in the second and third years of the reign of her Majesty Queen Victoria, intituled, "An Act for regulating the Police Courts of the Metropolis," or one of the justices of peace courts in Scotland, may hear and determine any complaint charging any person with practising medicine without a certificate as aforesaid, on the oath of one or more witnesses, or by his own confession, and shall award the penalty or punishment herein provided for such offence. And be it enacted, that in every case of the adjudication of a pecuniary penalty under this Act, and of non-payment or non-recovery thereof by distress, it shall be lawful for the magistrate to commit the offender to any gaol or house of correction

within his jurisdiction, for a term not exceeding *one* calendar month when the sum does not exceed *forty shillings*, and for a term not exceeding *three* calendar months when the sum does not exceed *five pounds*.

20. *Application of Penalties.*—And be it further enacted that any sum or sums of money arising from conviction and recovery of penalties for offences committed against the authority and provisions of this Act, shall be paid to the account of the Medical Registration Fund aforesaid, towards defraying the expenses of this Act.

21. *Uniformity of education, qualificatirn, and fees throughout the kingdon.*—And be it enacted, that the several colleges and other examining bodies shall, from time to time, prepare and lay before the said Secretary of State a scheme or schemes of the course of study, and particulars of the examination, to be passed by all persons applying to such colleges and other bodies respectively for letters testimonial as a physician, or surgeon, or apothecary, and also an account of the fees proposed to be taken by the said colleges and bodies respectively for such letters testimonial. And whereas it is expedient and desirable that the qualifications and fees for the said testimonials should be uniform, according to the nature thereof, throughout Great Britain and Ireland; such scheme or schemes shall therefore be of no force or effect until they shall have been submitted to her Majesty in council, and shall have received her Majesty's sanction and approval.

22. *Inspection and Supervision of Examinations.*—And be it enacted, that the said Secretary of State may, from time to time, require returns to be made in such form, and including such particulars as he shall think fit, respecting the examination to be conducted for medical degrees, diplomas, and licences, and it shall be lawful for any person deputed by the said Secretary of State, being a physician, surgeon, or apothecary, registered under this Act, to be present at any of the said examinations, and to report to the said Secretary of State, and if he shall be of opinion that the regulations approved by her Majesty in council for the examination and grant of letters testimonial as physician, surgeon, or apothecary, have been infringed, evaded, or neglected by any of the examining bodies, it shall be lawful for the said Secretary of State to admonish the said offending body; and if such admonition be neglected, then to direct the registrars as aforesaid to refuse to register upon the testimonials of the body so in default, until the conduct of such body shall be altered to the satisfaction of the said Secretary of State.

23. *Examiners may take Candidates to Hospitals, &c. for practical Examination.*—And be it further enacted, that the duly appointed examiners of candidates for degrees, diplomas, and licences in medicine, shall be empowered, under such regulations and restrictions, and at such times, as shall be approved by the Secretary of State as aforesaid, to attend with the candidates for examination at the public hospitals, or other public medical institutions, and also at any workhouse, for the purpose of ascertaining the practical knowledge of such candidates, from an inspection of sick and diseased persons.

24. *Act not to affect examinations of Students of Two Years' standing.*—And be it enacted, that students in medicine who at the time of the passing of this Act shall have been engaged two years and upwards in attending lectures in any medical school, or the practice of a public hospital, or other institution, in conformity with the regulations of any college having power to confer degrees or diplomas in medicine or surgery, shall not be affected, while completing their studies, or in passing their examinations, by anything in this Act contained; but such students shall be entitled to complete their education, and undergo their examinations, as though this Act had not been passed.

25. *Act not to extend to Dentists or Cuppers in business before 1st September, 1816.*—And be it enacted, that not anything in this Act contained, shall extend, or be construed to extend, to the profession or business of any dentist or cupper, who has engaged in such profession or business on or before the first day of September, eighteen hundred and forty-six; but every such dentist or cupper shall conduct such profession or business in as free and ample a manner as though this Act had not been passed.

26. *Act not to affect the trade or business of Chemists and Druggists.* (*Fifty-fifth George III., c.* 194, *s.* 28.)—Provided always, and be it further enacted, that nothing in this Act contained shall extend, or be construed to extend, to prejudice, or in any way to affect, the trade or business of a chemist and druggist, in the buying, preparing, compounding, dispensing, and vending drugs, medicines, and medicinable compounds, wholesale or retail; but all persons using or exercising the said trade or business, or who shall or may hereafter use or exercise the same, shall and may use, exercise, and carry on the same trade or business in such manner, and as fully and amply, to all intents and purposes, as the same trade or business was used, exercised, or carried on by chemists and druggists before the passing of this Act.

27. *Registered Medical Practitioners exempted from serving on Juries, Inquests, &c.*—And be it enacted, that every person who shall be registered and possess a certificate in force under the provisions of this Act shall be exempt, if he shall so desire, from serving on all juries and inquests whatsoever, and from serving all corporate, parochial, ward, hundred, and township offices, and in the militia, and that the name of such person shall not be returned in any list of persons liable to serve in the militia, or in any such office as aforesaid; and no person shall be entitled to such exemption as aforesaid on the ground of being a physician, surgeon, or apothecary, who does not possess such certificate then in force as aforesaid, any Act to the contrary notwithstanding.

28. *Expulsion of Registered practitioners for disgraceful conduct.*—And be it further enacted, that if registered practitioners shall at any time complain to

the council of any medical college or other governing medical body, that a person who had obtained his diploma or other qualification from such college or body has been conducting himself in a manner calculated to bring scandal and odium on the profession, by publishing indecent advertisements or pamphlets, or immoral or obscene prints or books, or has been guilty of any other disgraceful and unprofessional behaviour, the said council or governing body aforesaid are hereby empowered to cite the person accused before them, first giving him due notice and a full statement of the charges against him; whereupon the said council or other body, having heard the defendant, and being satisfied that the charges have been proved, or, in default of his appearance, having decided that the charges are proved, they are hereby authorized to erase the name of such person from the rolls of the said college or other institution, and shall transmit forthwith to the registrar of that part of the kingdom wherein such college or other institution is situated, an official report of their decision, authenticated by the seal of such college; and the said registrar shall thereupon strike out the name of the offending party from the register in his custody; and it shall ever afterwards be excluded from every register to be kept under the provisions of this Act, unless the council or other governing body by whom the name was first erased shall re-admit it into the rolls of their college or other institution.

29. *Names of Criminal Practitioners to be Erased from the Register.*—And be it enacted, that if any registered physician, surgeon, or apothecary, shall be convicted, in England or Ireland, of any felony, or in Scotland, of any crime or offence inferring infamy, or the punishment of death or transportation, or if it shall be found, by the judgment of any competent court, that any such physician, surgeon, or apothecary, shall have procured a certificate under this Act by any fraud or false pretence, or that any such physician, surgeon, or apothecary, has wilfully and knowingly given any false statement, evidence, or certificate, in any case in which by law the evidence or certificate of a physician, surgeon, or apothecary is required, every registrar, on production before him of an office copy, or extract of the conviction or judgment of the court duly certified under the hand of the proper officer of the court, shall cause the name of such physician, surgeon, or apothecary, to be erased from the register; and every person whose name shall have been so erased after such conviction or judgment as aforesaid, shall thereby forfeit and lose all the privileges of a registered medical practitioner provided by this Act.

30. *Interpretation Clause.*—And be it enacted, that the words "medicine" and "medical," when used in this Act, shall also mean and include the words, "physic," "surgery," and "surgical."

31. *Public Act.*—And be it further enacted, that this Act shall be deemed and taken to be a public Act, and shall be judicially taken notice of as such by all judges, justices, and others, without being specially pleaded.

SCHEDULES TO WHICH THIS ACT REFERS.

SCHEDULE (A.)

THE MEDICAL REGISTER FOR ENGLAND,

Consisting of the Names, Qualifications, with the Dates thereof, and Places of Residence, of all persons legally authorised to practise Medicine in England and Wales in 1848.

NAMES.	QUALIFICATIONS, AND THEIR DATES.	PLACES OF RESIDENCE.
Addison, James Price	Degree of M.D. from the University of Edidburgh, dated August, 1830.	No. 16, Tudor-street, Manchester.
Adlard, Hugh.....	Diploma as Fellow of the Royal College of Surgeons, Ireland, dated June, 1841.	No. 7, Milton-street, Hanover Square, London.
Admonds, Richards..	Licence of the Society of Apothecaries, London, dated March, 1834.	No. 19, Millsom-street, Exeter.
Adney, Ralph.....	Licence of the Royal College of Physicians, London, dated April, 1839.	No. 54, Holland-street, Liverpool.
Adpart, Erasmus	Diploma as Member of the Royal College of Surgeons of England, dated November, 1843.	No. 40, Tollville-street, Leeds.
Adwin, Gilbert.....	Declaration as required by the Act, of having practised as an Apothecary before 1st August, 1815.	The Grove, Camberwell, Surrey

SCHEDULE (B.)

DECLARATION required of a person who claims to be registered an APOTHECARY upon the ground that he was in practice as an Apothecary before the first day of August, 1815.

To the Medical Registrar for England.

I [Samuel Baker,] residing at [6, Duke Street, Exeter,] in the County of [Devon,] hereby declare that I was practising as an Apothecary at [16, George Street, Hastings,] in the county of [Sussex,] before the 1st day of August, 1815.

(Signed,) [*Samuel Baker.*]

Dated this [6th] day of [October,] 1847.

SCHEDULE (C.)

THE MEDICAL REGISTER FOR ENGLAND.

Registration Certificate for 1848.

By virtue of the powers vested in me by an Act of Parliament passed in the eleventh year of the reign of her Majesty Queen Victoria, intituled, "An Act for the Registration of Qualified Medical Practitioners, and for amending the law relating to the Practice of Medicine in Great Britain and Ireland;" I hereby certify, that [JAMES HOWARD,] residing at [15, Ormond

Street, Manchester,] in the [county of Lancaster,] has been duly registered according to the provisions of the said Act, as a person who is qualified to practise medicine in any part of England and Wales, and that he is entitled to exercise all the powers and privileges conferred by the said Act.

This certificate to remain in force until the 31st day of December, [1848,] and no longer.

(Signed,) [*Henry Brown,*]
Medical Registrar for England.

Dated, London, 6th October, 1846.

A MEMORIAL

Presented to the Rt. Hon. Sir George Grey, Bart., M.P., *Her Majesty's Principal Secretary of State for the Home Department, by the* Royal College of Physicians of London, *August* 8, 1846.

The President and Fellows of the Royal College of Physicians are induced respectfully to address Sir George Grey, as Her Majesty's Secretary of State for the Home Department, because they are unable, without the aid of the Legislature, to complete certain changes in their constitution which appear to be called for by the state of the Profession and of society, and which they have long contemplated and desire to carry into effect.

The College is bound by its charter of incorporation, granted by Henry VIII, and subsequently confirmed by Act of Parliament, to examine and to license, if found competent, all persons who desire to practise as Physicians in London and within seven miles round. But the office of examining and licensing those who wish to practise beyond seven miles from London was given by the Act which confirmed the Charter, not to the College at large, but to a small Body composed of eight of its Members, termed Elects. The Elects not having been chosen, even at first by the Members at large, are endowed with separate functions, which they exercise independently of the College, the constitution of their Body being such, that all vacancies occurring in it are required to be filled up by the survivors.

As might be expected, inconveniences have arisen from this divided jurisdiction. And it is worthy of observation, that amongst all the grievances complained of in the Petitions for Medical Reform which were presented at one time, in great number, to Parliament, none were complained of more than the existence of local and exclusive jurisdictions; and the exercise, by numerous independent Bodies, of the power of examining and licensing Medical Practitioners. The latter circumstance, it was alleged, had caused a want of uniformity in the education and qualifications of Practitioners passing under the same denomination; and from the former circumstance it has resulted, that Licenses valid in one part of the Country are invalid in another,—a restriction which proves most detrimental to the good of the Profession, and even leads frequently to an infringement of the Laws.

Of late years it has happened that the demand by Physicians for Licenses to practise in the Country (termed Extra-Licenses,) which was formerly small, has been greatly increased: hence the evils and inconvenience of the Licenses emanating from the College being divided into two kinds, and of their being granted by separate Bodies, have become strikingly manifest, and have given rise to complaints, and caused disputes and dissensions in various parts of the Country.

Moreover, the Act of Parliament, already referred to, has also given to the Elects the function of choosing annually one of themselves to be the President of the College. It has been thought that this part of the constitution of the College is susceptible of improvement; for that the choice of the President ought not to be deputed to so small a body, which is neither elected by the Fellows at large, nor under their control.

For the reasons which have been stated, the College is desirous that a short Act of Parliament should be passed, enabling it to accept a Charter modifying its former Charter, as regards the Elects, and transferring their functions to the general Corporation. An Act for this purpose was in fact prepared, with the sanction and co-operation of the late Government, and laid before Parliament. But it proceeded no farther, because it was introduced in conjunction with other measures affecting the Profession more widely, which were subsequently abandoned.

There are other improvements, lying more within its own power, to which the College has of late years directed its earnest attention.

In particular, it has extended, and greatly improved the examinations of those whom it licenses to practise as Physicians.

With respect to those who are admitted as Fellows or Members of the Corporation, during very nearly two centuries, they were required, by the Bye-Laws of the College, almost exclusively to have been educated at the English Universities; so that by long prescription the Graduates of Oxford and Cambridge were admitted nearly as a matter of course into the order of Fellows; and, beside them, few indeed either were, or could be elected.

The object of this regulation was to ensure in the Fellows of the College the best and highest education. And it had, confessedly, the effect of raising highly the character of the College, and, through its influence, that of all orders of the Profession in this country.

Nevertheless the exclusiveness of the rule excited jealousy and discontent, and became a cause of frequent litigation, until, by repeated decisions of the Courts of Law, the right of the College to be the sole judge of the qualifications of those whom it would elect as Fellows had been established beyond dispute.

In the present century, a high standard of education being adopted more generally, the restriction in favour of the Universities of Oxford and Cambridge, which had been enforced so long by the College, became proportionately less requisite and proper.

Wherefore the College, although still retaining a conviction of the superior advantages to be derived from an education in those Universities with which it had been so long connected, has, nevertheless, rescinded its exclusive Bye-Laws.

For several years the Fellows have been selected out of the Order of Licentiates; solely from regard to their character and attainments, and without distinction as to the place of their education.

To a considerable extent this plan has proved satisfactory to the Profession. Yet a system of selection is attended always with some invidiousness. Therefore the College has resolved to adopt another principle in the admission of Fellows, not liable to the foregoing objections, which will be perfectly equitable in its operation, and most honorable to those who avail themselves of it: viz., that the ordinary mode of admission to the Fellowship shall be through an examination, high in character, comprehensive in extent, and open to all Licentiates who may submit themselves voluntarily to it. Whilst, at the same time, a limited power shall be preserved to the College of admitting as Fellows, without examination, those persons who may have greatly distinguished themselves by scientific pursuits and discoveries; who, not having enjoyed the advantage of the best early education, may have made up for this deficiency by superior talents and energy, but whose age may be such, as well as their known attainments, that they ought to be exempted from the examination intended for younger men.

As far as the College is concerned, the changes and improvements which have been mentioned might have been effected earlier, had they not been retarded by circumstances over which the College could have no control. An outline of the Reforms contemplated by the College was submitted to the Marquis of Normanby when Secretary of State, and was favourably entertained by his Lordship. A change, however, in the Government followed soon afterwards, and delayed further progress.

The subject of these Reforms was repeatedly brought under the consideration of Sir James Graham, and they met with his approval; but it seemed to him expedient that they should be brought forward simultaneously with the general measures which he contemplated for the regulation of the whole Medical Profession.

In consequence of the desire then expressed by the Government, the College proceeded, with the assistance of its own legal advisers and those of the Crown, and with considerable pains and expense, to prepare the Draft of a new Charter, modifying its former Charter in the way which has been already explained.

The title of the College of Physicians of London was to be changed by the new Charter to that of the "Royal College of Physicians of England;" and, by one of its clauses, the College offered, for one year after its acceptance, to admit as Members, without examination, all Graduates of British Universities of a certain standing, now practising throughout England and Wales.

A conciliatory measure of this kind appears to be much required in the present state of the Medical Profession; for there are many Physicians practising in England, not being Graduates of Oxford or Cambridge, who yet are not, as legally they ought to be, possessed of a License from the College of Physicians of London.

Therefore the College proposed this measure as the commencement of a more regular and effective system, and in order that it might, more perfectly than is possible at present, represent and regulate the interests of all Physicians in this country.

The College will be ready to abide by the offer and concession which it then thought right to make, provided means can be devised whereby all Physicians practising in England and Wales shall henceforward (reserving the rights of the Universities of Oxford and Cambridge,) be required to submit their pretensions to the Censors' Board, (to which the College deputes the Examination of those whom it licenses,) in order that their competency may be properly tested, and that they may be enrolled as Members of the College.

By another Clause in the new Charter, power was given to the College, in certain specified cases, to expel unworthy Members. As circumstances sometimes arise requiring the exercise of such a power, the College believes that it would be expedient that it should possess it. A similar power has recently been given by Charter to the College of Surgeons.

It was also provided by the new Charter, that persons who having exceeded the age of forty years, and, having been duly examined by the College, are found competent to practise as Physicians, shall be entitled to use the designation of Doctor of Medicine, although not Graduates of any University. Whereas, for all Candidates who present themselves for the License under the age of forty, it is made an indispensable requisite that they should have obtained the Degree of Doctor of Medicine in some recognised University, before they can be admitted to examination by the College.

The reason of this distinction is, that in a practical Profession, like that of Medicine, it is always right that those who, by superior talents and industry, have raised themselves in public estimation, should have the power of rising from a lower even to the highest rank in the Profession. It seems reasonable that the College, to which such persons must apply for Legal Authority to practise as Physicians, should be empowered to confer the title, which through common usage is necessary to render the License intelligible by the Public and useful therefore to the possessor of it. In this way a want which is occasionally felt in the Profession might be supplied, without detriment to the Universities, and without material infringement of the rule, which ought to be upheld, that those who intend to be Physicians, should resort to the Universities for preliminary and general Education.

Such being the objects and principal enactments of the new Charter which has been prepared for the College, the salutary changes which it would effect are calculated, in the opinion of the College, to render it an Institution more generally acceptable to the Physicians of this Country, and more useful to the Profession and the Public.

Therefore, the College respectfully but earnestly requests the assistance of Government, in order that

a short Act of Parliament may be passed, enabling the Crown to grant this Charter, on the Petition of the College, and in order that the Crown may be advised to grant it.

FRANCIS HAWKINS, M.D., *Registrar.*

Medical Intelligence.

OPERATIONS PERFORMED UNDER THE INFLUENCE OF ÆTHER.

The announcement of a new means of performing surgical operations without pain has excited such general interest, and been already so extensively diffused throughout the country, that it is now merely necessary to bring forward, from time to time, such evidence of the efficacy of the new mode, as shall enable us to estimate its advantages, and to appreciate aright those circumstances under which it may hereafter be available, or otherwise, for effecting the end in view. The evidence on which the inhalation of æther, as a means of producing narcotism and insensibility to pain, was first introduced into this country, will be found detailed in the recent number of the *British and Foreign Medical Review*. From this it appears, that Dr. C. F. Jackson and Dr. Morton, of the United States, are the authors of the discovery. The following is an extract from a letter to Dr. Forbes, dated November 29th, from Dr. Ware, of Boston, a gentleman with whom many of the members of the Provincial Association had the gratification of becoming personally acquainted, at the Anniversary Meeting at Norwich.

Dr. Ware writes,—"I found on my arrival here, a new thing in the medical world, or rather, the new application of an old thing, of which I think you will like to hear:—It is a mode of rendering patients insensible to the pain of surgical operations, by the inhalation of the vapour of the strongest sulphuric æther. They are thrown into a state nearly resembling that of complete intoxication from ardent spirits, or of narcotism from opium. This state continues but a few minutes—five to ten—but during it the patient is insensible to pain. A thigh has been amputated, a breast extirpated, teeth drawn without the slightest suffering. The number of operations of various kinds, especially those in dentistry, has been very considerable, and I believe but few persons resist the influence of the agent.

"The effect is not exactly the same on all. In some the insensibility is entire, and the patient is aware of nothing which is going on; in others, a certain degree of the power of perception remains; the patient knows what the operator is doing, perceives him for example, take hold of a tooth and draw it out, feels the grating of the instrument, but still has no pain.

"There are no subsequent ill effects to detract from the value of this practice, none even so great as those which follow a common dose of opium. One person told me she had some unpleasant sensations in the head for a short time, and was weak, languid, and faintish through the day, but not more so than she ordinarily was from having a tooth drawn. Another told me that he experienced something of the same kind, and in addition, that his breath smelt very strongly of æther for forty-eight hours, and was indeed so strongly impregnated with it, as to affect the air of the room in which he sat, so as to be disagreeable to others."

The method has been used by Dr. Warren, of Boston, who up to the 24th of November, had applied it in six cases with satisfactory success, and no unpleasant sequel.

Dr. Bigelow thus describes the process followed:—"A small two-necked glass globe contains the prepared vapour, with sponges to enlarge the evaporating surface. One aperture admits the air to the interior of the globe, whence, charged with vapour, it is drawn through the second into the lungs. The inspired air thus passes through the bottle, but the expiration is diverted by a valve in the mouth-piece, and escaping into the apartment, is thus prevented from vitiating the medicated vapour."

He then mentions several cases of operations performed under the influence of the inhalation,—chiefly extraction of teeth and amputations.

The first operations of the kind performed in this country were by Mr. Liston, at University College Hospital. One of these was a case of amputation of the thigh, the other the partial removal of the nail in onychia. The method has since been had recourse to with success in the Richmond Hospital, Dublin, by Dr. J. MacDonell, in a case of amputation of the arm; at the Bristol General Hospital, by Mr. Lansdown, in a case of amputation of the thigh; at Wolverhampton, by Mr. G. Edwards, also a case of amputation of the thigh, reported in the present number of this Journal; at Addenbrooke's Hospital, Cambridge, by Mr. Humphry, in removal of the finger, &c.

The following is an extract from a letter from Mr. Humphry to Mr. Crosse, the President of the Provincial Association, dated January 2, 1847:—

"I have tried the inhalation of æther with perfect effect, the patient not having the slightest consciousness of pain whilst I quickly removed a finger and part of the metacarpal bone. It promises very great things, and seems to be attended with very little bad effect. The students have experimented on themselves, and were unconscious of pain from pricking, nipping, &c., whilst under the æthereal influence."

In the cases operated upon by Mr. Liston, the vapour was administered by an apparatus, consisting "of the bottom part of a Nooth's apparatus having a glass funnel filled with sponge, soaked in pure *washed* æther, in the upper orifice, and one of Read's flexible inhaling tubes in the lower." The æther falling through the funnel became vaporized, and the vapour descending to the bottom of the vessel, was thence inspired through the flexible tube.

The apparatus used at Bristol is described by Mr. Herapath as follows:—

"A common, but very large, bladder should be fitted with a collar to which an ivory mouth-piece with a large bore can be screwed. Without the intervention of any stopcock pour in about an ounce of good common æther, and blow up the bladder with the mouth till it is nearly full; place the thumb on the mouth-piece, and agitate the bladder so as to saturate the air in it with the vapour. As soon as the patient is ready for the operation, close his nostrils, introduce the mouth-piece, and close the lips round it with the fingers. He must now breathe into and out of the bladder, and in about one or two minutes the muscles of his lips will lose their hold. This is the moment for the first cut to be made. In two or three minutes the effect will begin to disappear; the mouth-piece should be again introduced, and this repeated as often as required. If the pulse should indicate a sinking of the patient, a little wine will restore him. I have no doubt but the inspiration of nitrous oxide (laughing gas,) would have a similar effect upon the nerves of sensation as the vapour of æther, as I have noticed that persons under its influence are totally insensible to pain; but I do not think it would be advisable to use it in surgical cases, from its frequently producing an ungovernable disposition to muscular exertion, which would render the patient unsteady, and embarass the operator. "The administrator of the vapour will of course take great care that no fluid æther shall be allowed to be drawn into the lungs, otherwise suffocation would result, or at the best a violent cough, which must protract the operation, and considerably distress the patient."

NEW VEGETABLE ALKALI.

At a recent meeting of the Chemical Society, Mr. Porrett read a paper "On the existence of a new Vegetable Alkali in Gun-Cotton," to which he has given the name "Lignea." He obtained it by the solution of gun-cotton in nitric acid, heated to between 100° and 180° Fahrenheit. On dropping this solution into water a white precipitate formed, having all the characters of gun-cotton, without fibre. Bicarbonate of potash effectually neutralized the solution, giving rise to nitrate of potash, and a copious whitish-grey precipitate,—a carbonate, probably, of the new alkali. When hyponitrous acid was made to act on an aqueous solution of the alkali, a synthetical proof of its existence was obtained, by the reproduction of hyponitrite of the oxide of lignin (gun-cotton.) Mr. Porrett conceives that lignea may by formed by the decay of woody fibre, and may thus be found to exist as an acetate in the sap of vegetables. Its chemical composition would be one equivalent of lignin, two of oxygen.

MEDICAL APPOINTMENT.

Mr. Benjamin Phillips has been elected Surgeon to the Westminster Hospital, in the room of Mr. Anthony White, resigned; and Mr. Barnard Holt, Assistant Surgeon, in the room of Mr. Phillips. Mr. Anthony White has been appointed Consulting Surgeon to the Hospital.

ROYAL COLLEGE OF SURGEONS

Gentlemen admitted Members on Tuesday, Dec. 29, 1846:—E. Archer; W. L. Dudley; R. B. Roscow; J. White; W. Morgan; F. W. Richardson.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, Dec. 24th, 1846:—Joshua Lever, Bolton le Moors; Henry Turner Lane Rook, Barnstaple; Richard Budd Painter, Westminster; Robert Allen, Cartmel; Francis Sibery, Long Clawson; James Edmund Clutterbuck, Newark Park, Gloucestershire.

Thursday, December 31st, 1846:—Cornelius Black, Chesterfield; Charles Thompson, Leicester.

OBITUARY.

Died, November 26th, at Parma, aged 76, the celebrated Italian Professor Tommasini.

Dec. 14th, in Charles Street, Manchester Square, London, John Foley, Esq., M.D.

17th, aged 80, M. Broussonet, Professor of Clinical Medicine in the School of Montpellier.

23rd, in Dublin, aged 61, John Bickerson Flanagan Esq., late Surgeon of the 4th Dragoon Guards.

26th, at Lower Garthmyl, Montgomeryshire, aged 73, Edward Johnes, Esq., M.D.

Jan. 1st, at Hereford, F. B. Glaspole, Esq., M.D.

Lately, Peter Milner, Esq., Surgeon, of Mirfield, near Dewsbury, Yorkshire.

BOOKS RECEIVED.

A Treatise on the Plague: more especially on the Police Management of that Disease, &c.; with Hints on Quarantine. By A. White, M.D., Deputy Inspector-General of Military Hospitals, and late Superintendent of the Plague in Corfu, &c. London: Churchill. 1846. 8vo. pp. 342.

Practical Remarks on Near Sight, Aged Sight, and Impaired Vision, &c. By William White Cooper, F.R.C.S., Senior Surgeon to the North London Ophthalmic Institution, &c., &c. London: Churchill. 1847. Post. 8vo. pp. 216.

Report of Henry Austen, Esq., C.E., Honorary Secretary to the Health of Towns' Association, on the Sanatory Condition of the City of Worcester: with an Appendix, by Edwin Chadwick, Esq., Barrister-at-Law, and Secretary to the Board of Poor-Law Commissioners. Worcester: Eaton and Son. 1847. 8vo. pp. 46.

TO CORRESPONDENTS.

Communications have been received from Mr. Bartrum; Mr. J. W. West; Dr. Badeley; Mr. Addison; a Member of the Association; the Sexagenarian M.A.; Mr. Cotton; the Society of Apothecaries; the Sheffield Medical Society; Dr. Belcombe.

It is requested that all letters and communications be sent to Dr. Streeten, Foregate Street, Worcester. Parcels and books for review, may be addressed to the Editor of the Provincial Medical and Surgical Journal, care of Mr. Churchill, Princes Street, Soho.

DESCRIPTION OF AN APPARATUS FOR INJURIES AND DISEASES OF JOINTS, WITH OBSERVATIONS AND CASES.

By Benjamin Barrow, Esq.,

Fellow of the Royal Medico-Chirurgical Society, and formerly Resident Surgeon at St. Bartholomew's Hospital, London.

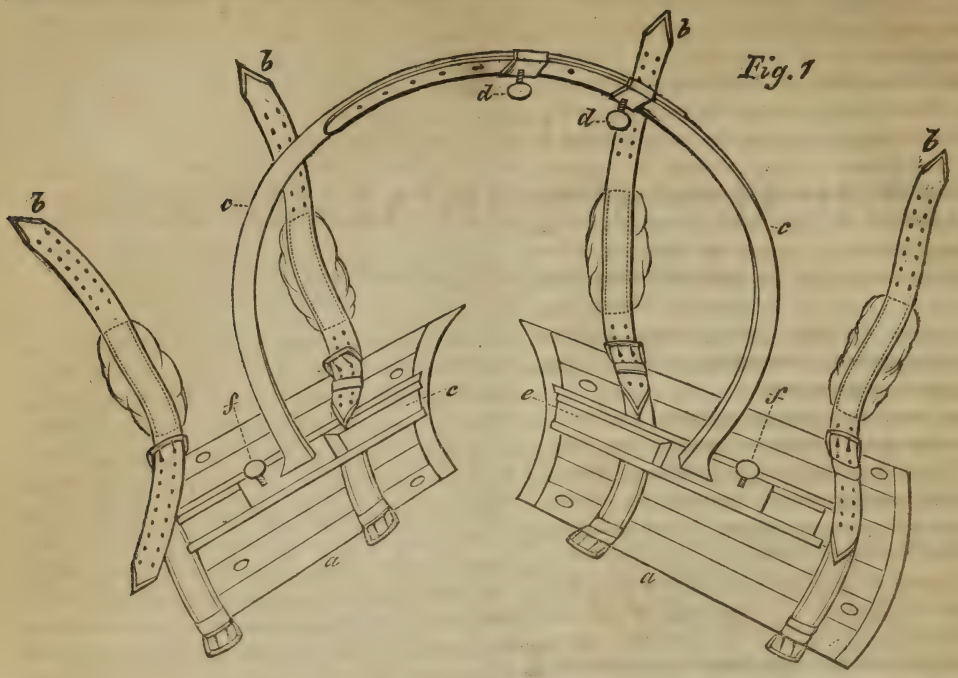
The following observations are submitted to the public in the hope that they contain some novelties, the knowledge of which will be found useful in the management of diseased and injured joints.

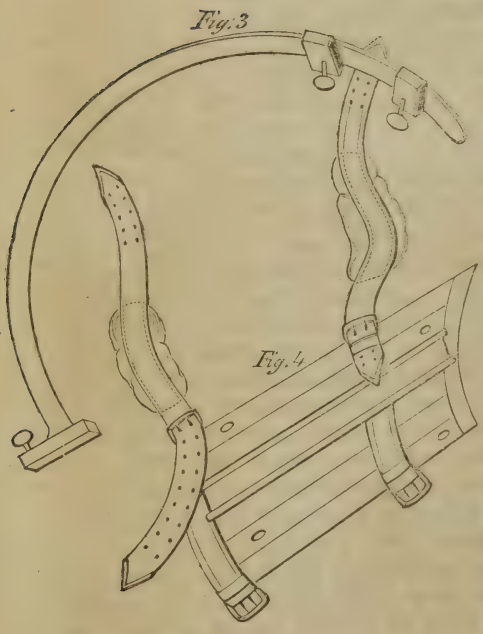
An almost constant attendance for ten years at St. Bartholemew's and other large Metropolitan and Continental Hospitals, and some years of private practice, have afforded me in the first place, many opportunities for comparing the various modes employed in the treatment both local and general of injuries and diseases of joints; secondly, the results arising from these various plans; and lastly, how the means and apparatus in general use might be improved and deficiencies supplied. I must premise that it is not my intention to enter more minutely into the history of these cases, either as regards the course they run, or the treatment ordinarily employed, than may be necessary for the clear explanation of the apparatus which I am desirous of introducing to general use; for the valuable treatise upon the subject of the diseases to which joints are liable by Sir Benjamin Brodie, precludes the necessity, I might say the possibility, of any subsequent writer, however great his experience, adding to it any important information.

The prominent position which the joints, especially the elbow and knee, hold in the human frame, augments considerably their liability to receive more frequently than other parts of the body external injuries; no parts are so prone to inflame as the joints; in no part wherein inflammation has once set up, does it increase so rapidly as in the synovial membrane, which renders it so much the more important that all motion in a joint should be immediately restrained and altogether prevented after the first appearance, however slight, of inflammation, at the same time that all necessary local remedies are efficiently applied. To obtain this end has been my object, and to explain the requisites for carrying out the above measures, and at the same time to direct more attention than it appears to me has hitherto been done, *to the quiet treatment* which diseases and injuries of the joints in every stage require.

I believe it will be found that by the aid of the splint,* represented in the cut, *Fig.* 1, the objects just named may be efficiently carried out, as also the views and directions of Sir Benjamin Brodie most fully complied with. These views and directions I cannot do better than give in his own words,—he says, "Not only in cases of inflammation of the synovial membrane, but in all other cases in which actual disease of a joint exists, the disease, whatever it may be, is kept up and aggravated by motion and exercise, and whatever means can be employed so as to keep the joint in a state of complete repose will go far towards the production of a cure. In the early stage of acute inflammation of the synovial membrane, indeed no interference on the part of the surgeon is necessary for this purpose, the pain which the patient experiences, in every attempt made to use the limb being sufficient to prevent him using it. But it is otherwise when the inflammation has in a great degree subsided. At this period the motion of the joint occasions little or no inconvenience at the time, although it invariably tends to aggravate the symptoms afterwards. It is difficult to persuade a patient thus situated to submit to a very rigid system of confinement, and if he should do so, there is always danger in protracted cases that his general health may suffer in consequence. It is important that he should not be altogether deprived of the opportunity of taking air and exercise; yet it is necessary that the affected joint should be kept in a state approaching as near as possible to one of complete repose. This double object may be attained by means of a proper bandage applied so as to restrain the motions of the joint, at the same time that it makes no more than a moderate degree of pressure on it. As to the best mode of carrying this plan into execution, the surgeon must exercise his own judgment in each individual case. If the disease be far advanced, and there is danger of the cartilages

* The Society of Arts of London awarded the silver medal for the year 1841, for this apparatus.





being ulcerated, he will find it prudent to restrain the motions of the joint altogether."

Upon these observations I must venture to make one or two comments. The first I would offer is, that there has always appeared to me to exist, even from the commencement of inflammation in the synovial membrane, the *greatest* necessity for keeping the affected joint *perfectly at rest;* for although pain however severe, be present in the first stages of the attack, and to such a degree, as in a great measure to prevent all voluntary motion, still we must all be sufficiently conscious of the many involuntary movements as it were, to which our limbs are subject, whether waking or sleeping, not to trust altogether to this pain as a restriction from motion,—motion which must more or less aggravate and increase the irritation already existing in the joint.

The great difficulty of restraining motion in, and avoiding pressure upon, the joint, at the same time that the full and complete application of all remedies necessary for the prevention of inflammation and alleviation of pain is carried on, has been, I am well aware, most frequently the cause of this part of the treatment being neglected; but I am in hopes that the apparatus represented by *Fig.* 1, will be found calculated to overcome, on future occasions, every similar obstacle.

Description of Cuts.

FIG. I.—(*a a*)—The wooden splints divided. *b b b b* the straps and buckles.

(*c c*)—The arc or bow. *d d*, the screws which bind together the two portions of the arc or bow. *e e*, the grooves in which the arc or bow moves, allowing the splints to be brought nearer to, or removed farther from, one another. *f f*, the screws which confine the portions of arc or bow in the grooves *e e*.

FIG. II.—Represents the screws or stops which allow of the two portions forming the arc or bow to move to a certain extent one upon the other.

FIG. III.—Represents one portion of the arc or bow removed from its groove.

FIG. IV.—Represents the wooden splint, with its straps and buckles attached.

That air and exercise are highly necessary, especially for those persons who are so frequently the subject of diseased joints, (viz., the scrofulous,) no one will deny. This end can, by means of the splint in question, be most fully attained, during the whole progress of cure of any disease or injury, allowing the requisite remedies to be at the same time continued, no pressure being applied to the joint itself,—a most prejudicial practice, particularly as regards the knee-joint, where the patella pressing upon the articular surfaces of the femur and tibia must, by the consequent friction, very much increase the injury already inflicted upon the joint by the previous inflammation, at the same time that it keeps up the irritation.

I may here remark that the apparatus I am about to describe has been invented some length of time, but I have delayed presenting it to my professional brethren until I had tested its utility in all those cases for which I considered it peculiarly adapted. It will be well also to observe, that the arc or bow, (*c.c., Fig.* 1,) which presents an awkward appearance, but with which I cannot discover the possibility of dispensing without very much impairing the value of the apparatus, may be unsightly, but still not inconvenient nor unnecessary, affording as it does complete protection to the joint, whether the patient be in bed, or up and about. A blow upon it when the splint is applied to the arm conveys no shock to the joint, the whole limb moving together from the shoulder. The same applies to the knee, when the splints are placed, one above, the other below, the joint. It will be observed, that the two splints (*a a, Fig.* 1,) are split, to allow of their close adaptation to the limb; they must be padded, and then firmly fixed, by means of the straps and buckles, *b b, b b,* (or by what would be much better, a piece of elastic webbing, extending the whole length of either splint, and laced at the side, for the narrow straps are very apt to act as ligatures, and to cause much pain and uneasiness from their unequal pressure,) one to the upper, the other to the forearm; or the one to the thigh, the other to the leg, as the case may be. The two splints are connected by the steel arc or bow *c c*, which is formed of two pieces, sliding one upon the other, in order to allow of the limb being brought to any angle, or placed straight, as occasion may require. This being accomplished, they are fixed by means of the screws, *d d.* Thus the two divisions of the limb are as it were connected, and consequently the joint kept perfectly at rest; at the same time being, as I have before stated, quite free for the application of all necessary remedies. It will be farther noticed that the two steel portions forming the arc or bow move in the brass grooves *e e*, in order to allow of the splints being moved nearer to or farther from the joint, as circumstances may arise; the bow being again firmly fixed in the grooves by the binding screws *f f.* The holes observable on one of the steel portions are to admit the small screws or stops represented by *Fig.* 2, and which allow of our giving to the joint moderate and gradual motion and extension; the binding screws *d d* being then removed, a strap may be fastened to any of the brass buttons *o o o o o o*, fixed to the splints; and this being carried round the neck and shoulders answers the purpose of a sling.

Fig.2

In addition to the cases to which I have alluded as likely to be benefitted by the use of this splint, I may add that it is extremely serviceable in cases of fracture of the patella, fully answering the purpose of all bandages hitherto employed, and which more or less interfere with the application of remedies, and with the joint itself. The two splints *a a* being brought as near as required, one to the upper, the other to the lower, end of the fractured portions, pressure as much as may be necessary to keep them in apposition and close connection can be most effectually accomplished, and kept up as long as there is that disposition to separate, which so frequently takes place as a consequence of the strong action of the muscles attached to, and surrounding the upper portion of the patella.

In like manner may the splint be most advantageously applied in cases of fracture of the olecranon, especially when the triceps muscle is strong, and we find the fractured portion drawn upwards some distance from the ulna. No accident is so likely to produce mischievous consequences to the joint, and interfere with its after utility, as fracture of the ulna, unless properly attended to in the first instance.

Contraction which so often follows inflammation of the joints, may be completely prevented by applying the splint in the early stages of the attack; and even should contraction have taken place, it may be overcome by means of the splint, the angle being changed *gradatim*, the joint being at the same time fomented and rubbed as may be desired. The great difficulty in the first place in preventing these contractions, and in the second, in overcoming them, has hitherto been the want of some apparatus which would leave the joint perfectly free, patients being unable to endure the pain consequent upon *constant* pressure. I, in common with every one, under whose care even a single case of contraction of the elbow or knee-joint has fallen, have had many occasions of observing, that unless the action be *constantly* persevered in, the limb, in a very short space of time, regains its previously-contracted position.

The splint will be found a useful adjunct to the means already employed in the treatment of those cases in which the tendons of the hamstring muscles are divided, on account of contraction or partial anchylosis of the knee-joint.

I have no doubt but that this apparatus will likewise afford most important aid in those cases in which the extirpation of the articular ends of the bones may be necessary; not only will it be found useful in main-

taining the limb at the required angle, and keeping it perfectly at rest after the operation, but it may be applied before the operation, supplying the place of an assistant, holding the two divisions of the limb much more steadily than can be done by the firmest hand, and not at all interfering with the surgeon's manipulations, the joint being free in its entire circumference.*

By slight modifications in the shape and size of the splints, and length of the straps, any joint in the body may, by means of this apparatus, be kept perfectly at rest, and guarded from external violence.

It is well here to add, that the splints require most careful padding and adjustment, for at some angles it will be found that either the upper one will be raised and the lower one depressed, or *vice versâ*. In such cases, unless the padding be good, inconvenience will be experienced by the patient, undue pressure being made on the soft parts.

Thus have I endeavoured to explain an apparatus most simple in its mode of action, easily managed, and made at a very moderate cost.†

I have selected from many others the following cases, in which I have employed my joint apparatus with the greatest advantage, and which I here recite without any comments as to the general and local treatment specifically used, and which were of course regulated in the various cases, according to their requirements:—

Case I.

A boy, aged ten years and a half, came under my notice, being afflicted with that condition of the right knee-joint, so common in scrofulous children. He had suffered more or less from this affection for several years; abscesses had formed, broken, and healed, from time to time; the leg became bent at right angles to the thigh, and thus the lad was almost incapacitated from moving about, except by hopping upon one leg, with the aid of a crutch. The least pressure upon the patella caused him so much pain, and increased the swelling so considerably, besides inducing inflammation, that any plan for gradually extending the leg, which in any way interfered with the joint itself, was obliged to be abandoned.

I recommended the use of my splint, which was accordingly employed for a lengthened period, at the same time that fomentations and soothing applications were constantly used around the joint. The angle of the splint was changed at first about twice a week, and then every other day, until the position of the limb was so much improved that the boy could walk tolerably well, at the end of three months, without the aid of crutch or stick.

The boy sometimes during the progress of this cure complained of so much pain that it was found necessary to remove the apparatus. In twenty-four hours the limb would have almost regained its right-angular position. To obviate as much as possible this inconvenience, and consequent retarding of the cure, whenever my splint was removed, I directed the foot to be tied to a foot-board, and a straight splint to be placed against the patient's heel and thigh. This plan had the desired effect of preventing the frequent retraction.

Case II

Occurred in a boy of about seven years, who was afflicted with a diseased elbow, bearing in every respect a strong resemblance to the knee-joint just described. The left arm was almost disabled; the swelling about the joint was very considerable; the bones were distinctly felt to grate one upon the other, shewing that the normal condition of their articulating surfaces was destroyed. Quietude, and a due application of proper local remedies, were the only chances of saving the limb. The *rest* was most effectually preserved by means of my joint-splint, and which allowed at the same time of as complete an application of remedies as could be desired. In this case the apparatus was kept applied for nearly five months, which perseverance was followed by the gratifying result of a fairly useful arm.

Case III.

A young man, of twenty-four years of age, whilst walking, slipped and fell, striking his elbow violently against the curb-stone. When I first saw him, about two hours after the accident, the limb around the elbow-joint was enormously swollen and bruised, so much so as to preclude the possibility of ascertaining whether there was fracture or not of either of the bones. I immediately fixed upon the arm my joint-splint, applied cold lotions, and on the following morning, about thirty hours from the time of the accident, the swelling had much subsided, and I detected a crepitus, proving that the olecranon was fractured. I put the arm in that position best adapted for such an accident, and then replaced the splint at the required angle. The lotions, &c., were continued, and every thing went on most prosperously, indeed there was not one drawback; the union of the bone was perfect in about three weeks; the motions of the arm were not at all impaired. The *perfect quiet*, and the constant application of the necessary remedies from the first, without any pressure upon the joint itself, may in a great measure account for the rapid decrease in the swelling, for the absence of all after inflammation or inconvenience, as also, for the speedy and perfect union of the fractured bone.

Case IV.

A little girl, aged eight years, was brought to me on account of a contraction at the bend of the elbow, following a burn. I learnt that the accident had occurred some five years previously from her wearing-apparel catching fire; that during the time the wound was healing the arm became bent; that the cicatrix had been divided twice, and that on the last occasion a

* A much larger bow than is necessary in most cases might be attached to the splints during the performance of the operation.

† Mr. Ferguson, surgical instrument maker to St. Bartholomew's Hospital, has always manufactured my splints, &c. I would advise all who employ this apparatus, to have the bows made of steel and not brass, for the latter material adds much to the weight of the splints.

portion of the hardened skin had been removed; that considerable difficulty had been after each operation experienced in keeping the arm extended, during the progress of the healing of the wound, caused by the division of the cicatrix, and that a common straight splint had been fixed upon the back of the arm, but from the pain and uneasiness consequent upon its constant pressure, it was found necessary to remove it very frequently, and at last to abandon its use altogether. I placed upon the arm my apparatus, and with a scalpel, just slightly divided the cicatrix upon the first day, placing the arm at the angle which this division allowed, without causing pain, and there fixed it by means of the joint-splint. Two days subsequently I again saw the child and effected another division of the cicatrix, about an inch from the first, again altering the angle of the arm, and at the same time that of the splint.

This operation I repeated at five different periods at about three days' interval, and at each time placed the arm and splint at the angle which I found compatible with the child's comfort; the arm had become perfectly straight in about six weeks; the splint was, however, still retained upon the limb, the straight position being occasionally changed for an angle more or less acute as the fancy took me, thus avoiding the chance of tiring my patient. During this latter period I ordered friction and fomentations, whereby I succeeded in softening very much the cicatrized skin. The arm in about three months had almost regained its natural appearance, and its usefulness is as great as that of its fellow

CASE V.

A man, thirty-six years of age, had the misfortune to fall and fracture his patella; he did not apply for surgical aid until some hours after the occurrence of the injury, imagining that he had only bruised his knee. Finding, however, that it became much swollen and very painful, he thought it advisable to seek relief, and upon examination I readily discovered that the above-named accident had occurred. I applied my apparatus, the upper edge of the lower splint pressing against the inferior portion of the patella, and the lower edge of the upper splint against the superior porion of the fractured bone. The two portions had become widely separated in consequence of the attempts made to walk and move after the fall, but this space was day by day much decreased by the gradual movement of the wooden splints nearer to each other, and which of course at the same time approximated the fractured surfaces of the patella. Leeches, poultices, and fomentations were during this period and until the limb was restored to use, frequently and satisfactorily applied; whilst the joint and fractured bone were kept perfectly at rest and all muscular action overcome by the constant application of the joint-splint.

I may mention that the limb was elevated in this case, as is usual in such accidents, at the same time that the splint was employed. These two measures combined, caused the patient no inconvenience, but on the contrary were a source of much comfort, and decidedly tended to the rapid and solid union of the fractured patella.

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(*Fourth Series of Experimental Researches.*)

By WILLIAM ADDISON, M.D., F.R.S., Malvern.

I. VEGETABLE TEXTURES.

The science of morphology, which treats of the gradual transformation of the primary elements of vegetable structures into the various special organs of the species, has long formed an interesting and essential department of physiological botany. The plan upon which the metamorphosis takes place, "is"—according to Dr. LINDLEY—"notwithstanding the infinite variety observable, extremely simple, and executed by modifications of the leafy texture."

If the structure of a leaf of flowering plants be carefully examined in very thin sections, with a sufficiently high magnifying power, (750 diameters linear,) it will be found composed of *two distinct cellular elements*, a fibrous tissue, spiral vessels, stomata, and an immense assemblage of air-vesicles, or air-bubbles. On the upper surface of the leaf, is a thin transparent homogeneous membrane, divided into a number of cellular compartments irregular in form and outline, and variable in size in different species of plants. On the under surface is a similar membrane, in which the cellular compartments are thickly interspersed with the stomata. The cellular compartments and irregular outlines thus visible on the under and upper surfaces of the leaf, are the exterior outer portion of a very fine and strongly coherent cellular texture, running through the entire thickness of the leaf, and so disposed as to form numerous divaricating air-passages connected with the stomata.* Within the meshes of this coherent cellular texture, around the walls of the divaricating intercellular air-passages, and in close apposition with the air contained within them, is a less coherent cellular element or texture, consisting of smaller and but slightly adherent corpuscles or cells filled with the green granules of the *chlorophylle*, each granule consisting of a number of minute molecules.

The term cellular tissue or texture has been indiscriminately applied to so many portions of vegetable structure, that it is necessary to state prominently the point which a careful microscopical examination of a leaf appears to me to establish between the coherent cellular textures, the cuticle and supporting framework, and the incoherent cellular texture forming the parenchyma.

If a thin section be taken from the main rib, or any of the other ribs of a leaf, the cellular texture disclosed has the following properties and appearance. It is strong and coherent; the spaces of the cells are

* These air-passages when a section of the parenchyma has been made, display *oval foramina*, similar to those seen in a section of a lung.

nearly or quite free from chlorophylle granules, and the cell-walls are comparatively thick, the structural material not occupying the central parts of the cells, but being collected at the cell-walls and apparently outside and between them.

If having previously sliced away the outer integument of the leaf, a thin section be taken of the green parenchyma, the cellular element displayed has a very different appearance. It consists of smaller distinct cells arranged around oval or rounded vacant spaces, and if the succulent leaf of *Sedum acre* be crushed between two slips of glass, the incoherent cellular elements are found scattered and dispersed upon them.

It is well known that two important functions are performed by leaves—respiration and secretion; and it appears from my examinations that in the leaves of *phanerogamia*, each function has its appropriate anatomical structure—the coherent cellular textures ministering to the form of the leaf, and to respiration; the incoherent cellular texture, to secretion or nutrition. That the interior of a leaf is full of air, may be demonstrated by a microscopical examination of the parenchyma; and that the air is situated in numerous air-passages, is also equally evident, at the same time. That this air may be forced out by heat, is readily shewn by immersing a leaf in boiling water, when the under surface becomes thickly coated with minute air-bubbles, which appear to escape by the stomata; for the upper surface of the leaf, if uninjured, never allows of the escape of similar bubbles. When, therefore, the broad upper surface of a leaf is exposed to the noon-day sun, the air occupying the air-passages must expand; and if all the passages be filled with air, some portions of it, altered doubtless by the respiring functions of the incoherent cellular texture, must escape, either through the stomata, in which the air-passages terminate, or by other means. But when the sun's rays are obscured by passing clouds, and at night, the air within the leaf, becoming colder, will contract in bulk, and there will be space for fresh portions of the outward air to enter. Heat or caloric, therefore, is the *efficient cause*; and change of temperature—sun and cloud—day and night—the *conditions* of respiration in the leaf; *inspiration* taking place during the passage of clouds, and at night; *expiration* going on when the sun shines upon the leaf.

In most of the herbaceous plants, the green matter of the lower leaves visibly disappears during the inflorescence and the growth of the seed, that is to say they wither and dry up. This is remarkably the case in the *sedums*, *lilies*, &c., and the fact is observable in all tender plants, should there be any lack of moisture at the important time of flowering. The following, among many other examples, may be related in illustration:—If a plant of the garden nasturtium (*Tropæolum majus*,) be pulled up whilst in vigorous growth in the autumn, and thrown upon the ground in the sun, it will continue flowering for a month or six weeks, putting forth new shoots, new flowers, leaves and seeds; but during all this time the older leaves are gradually, from below upwards, one after another, exhausted of their green matter, withering and shrivelling up. From these and many other facts well known to botanists, but which it is unnecessary to particularize, it is concluded that the green matter contained in the cells of the incoherent cellular texture of the leaf is of the nature of a secretion elaborated within the cells, giving sensible properties or qualities to the leaf, and essential to the growth of the subsequent parts of the structure, the flower, the seed, or the bud; while the coherent cellular texture gives form and stability to the leaf, and administers to the function of respiration.

The distinction between the coherent and incoherent cellular textures clearly exists in nature; the former may be seen in the wood and pith; the latter in the bark and leaves. These two textures may be oftentimes conjoined, and run by transitional stages into each other; still they are as frequently disassociated, and when they are so, they are as distinct in appearance and mechanical properties as they seem to be in function.*

The general nature of the parenchymatous part of leaves, which I have termed the incoherent cellular texture, has been well explained by Link and others, and was figured by Mohl, in 1828; but the most complete account is that of M. Adolphe Brongnart, in 1830, of which the following is an abstract:—

The cuticle is a layer of cellules, adhering firmly to each other, and sometimes but slightly to the subjacent tissue, from which they are entirely different in form and nature—in form, for the cellules are depressed, and in consequence of the variety of outline they present, form meshes, either regular or irregular; and in nature, because these cellules are perfectly transparent and colourless, and probably filled with air. They scarcely ever contain any organic particles, and are probably but little permeable, either to fluids or gaseous matter; while on the other hand, the cellules of the subjacent *parenchyma* are filled with the green substance that determines the colour of the leaf. Beneath the upper cuticle are two or three layers of oblong cells, generally of much less diameter than the cells of the cuticle, and therefore easily seen through it; the cells have little intervals or spaces between them, and in leaves that have stomata on their upper surface, there are among the cells some large spaces through which the stomata communicate with the interior of the leaf. On the under surface of the leaf, the cells of the parenchyma are irregular, often having two or three branches which unite with the

* Cellular tissue is found in three essentially different states, *membranous*, *fibrous*, and *parenchymatous*;—membrane and fibres combined form a fibro-cellular, and parenchyma and fibres form a fibro-corpuscular texture.

limbs of the cells next them, and so form spaces which are larger than the cells themselves, and either correspond directly with the stomata, or are in communication with them.*

(For examples of the incoherent cellular parenchyma of a leaf, and of the coherent cellular structure of the cuticle and ribs, I refer the reader to Dr. Lindley's "Introduction to Botany," plate 1, fig 2, 3, 6, and 7; plate 3, fig 5, ed., 1832.)

Mr. Edwin Lees, who is well known as an indefatigable and practical botanist, has permitted me to state his opinion upon the structure of a leaf.

"I have perused Dr. Addison's account of the vegetable tissue, and seen his demonstrations with the microscope repeatedly. It appears to me that the distinction of coherent and incoherent cellular structure, is not only correct in fact, but of considerable importance in a physiological point of view. It is clear that the coherent cellular structure forms the supporting frame-work of the leaf; and that it abounds with air is satisfactorily proved by Dr. Addison's experiment of immersing a leaf in boiling water, when the under surface gives exit to numerous air-vesicles. It therefore appears correct to attribute to this structure an important function in respiration; and it appears equally correct to suppose that the system of nutrition and secretion goes on in the cells containing the granules of chlorophylle, which are frequently found but very slightly coherent. The coherent and incoherent structures are not easily demonstrated perhaps as distinct structures in every leaf, but I believe they exist. Though well aware with other botanists that leaves carried on the operations of respiration and secretion, yet the different functions attributed to the two kinds of cellular tissue have never previously, I believe, been insisted on. The fact necessarily leads to inductions before undeveloped."—Edwin Lees, F.L.S., *Fellow of the Botanical Societies of London and Edinburgh.*

If the structure of a petal be examined in the same way with a microscope, we find a coherent cellular structure, abounding with air, to which indeed the whiteness and opacity of a white petal is wholly due. This coherent cellular texture has various forms, and the transparent homogeneous cell-walls are frequently marked with delicate *striæ*. The cells usually contain either a coloured fluid, or numerous coloured granules and molecules; and it is evident if the structural elements of a petal are formed by a process of metamorphosis from the leafy texture, that it is the green granular chlorophylle of the cellular parenchyma that has experienced the greatest amount of change;—in other words, whereas the colour of the leaf is green, and the colour of the petal blue, scarlet, or yellow, so therefore, if the structural elements of the petal are metamorphosed out of the leafy texture, it must be the incoherent cells containing the green matter,—the secreted and proper juices of the leaf, that have experienced the greatest amount of change. If we extend the microscopical examination to lower forms of vegetation, we find the fibrous or woody textures, and spiral vessels to disappear, the leaves of mosses and the fronds of ferns consisting wholly of cells, filled with a green matter, and rendered coherent by a thickening of their walls. Still lower, we find in the *conferfæ* elongated cells, joined end to end, each cell containing green granules of chlorophylle. Lastly, there are vegetable textures, consisting of cells filled with green matter, and of so slight a coherency, that the merest touch is sufficient to separate them from each other.

The order of vegetable structure then appears to be:—

1. Forms consisting of *incoherent cellular texture*; masses of cells or corpuscles with an interior (generally green) matter. These are the lowest forms—*algæ and lichens*, in which every cell or corpuscle is both a respiring and a secreting structure.

2. Forms consisting of *coherent cellular texture*; cells with an interior (generally green) matter, cohering either end to end as in the *confervæ*; or on all sides as in *fungi*, *mosses*, and *ferns*. Here again every cell is both a respiring and a secreting structure.

3. Forms consisting of a *compound cellular texture*, in which two distinct cellular elements with distinct functions are conjoined and co-exist; the coherent cellular element connected with the stomata and air-passages ministering to respiration, and the incoherent with the green granules of the chlorophylle within them executing the function of secretion. And it would appear that in the leaves of *phanerogamia*, there is a large quantity of air stored up in the air-passages, formed by the coherent cellular texture for the uses of the incoherent cellular texture. As we ascend in the scale of life and being, so we find more and more clearly special organs or textures appointed to special functions; let me therefore recapitulate the points I wish to urge upon the reader's attention. In the lowest forms of vegetable structure, the functions of secretion, growth and respiration, are conjoined in each cell or corpuscle, and these cells in many cases cohere so slightly, that the texture falls to pieces on being touched or handled. In some instances the structure is no more than a light cellular powder, and in others mucoid or soft. But in the leaves of phanerogamia, there is a coherent texture supporting the stomata and administering to the respiratory function; and also a less coherent texture executing the function of secretion.

I am sensible that the terms incoherent and coherent, as applied to the leaf, do but partially and inaccurately express the distinctions insisted on between the

* See, for a more detailed account of the structure of leaves, "Lindley's Introduction to Botany," particularly p. 85, ed., 1832.

secreting, the soft and brittle, cellular textures, and the non-secreting, coherent, and elastic ones; between the green cellular parenchyma, and the outer cellular membrane of the leaf. The distinctions are, however, very palpable, and in animal structures so important, that I purpose, in order to avoid confusion of terms, and yet preserve the distinctions set before us by nature, to use the term *corpuscular texture* for the *very* soft, opaque, and friable cellular textures, limiting the term *cellular* to those which are coherent, transparent, and elastic. For example, the liver and intestinal villi, I would say, are *corpuscular* textures; the lung a *cellular* texture;—the two former being opaque, friable, and incoherent; the latter transparent, elastic, and coherent; and if so, then there is *prima facie* evidence of an analogy between the blood of animals and the parenchymatous texture of a leaf.

REMARKS ON FEVER.

By William Davies, M.D., Physician to the Bath United Hospital.

(Read at the Quarterly Meeting of the Bath and Bristol Branch of the Provincial Medical and Surgical Association.)

The few remarks which I am about to submit to this meeting have reference to a disease which has, perhaps, given rise to more discussion in the medical world than any other, and concerning which there still remain various and conflicting opinions,—this is fever; and in what is to follow, I would be understood as referring to the common or idiopathic continued fever of this country, the general features of which every medical man is familiar with, more especially those who have past any part of their professional career in Edinburgh or Dublin.

My remarks shall be first on the nature of continued fever; and secondly, on the pathology of head-complication, as illustrative of what has preceded, and with reference to practice.

The two following propositions must be granted:—First, that the disease is communicable—or that an individual subjected to a sufficiently close intercourse with another labouring under continued fever, may become similarly affected.

Second. That in order to a disease being communicable, it is essential that certain matter shall pass off from the body of the individual affected, and be received into that of him who is to suffer. It is unimportant whether this entrance is effected by inoculation, or by means of atmospheric transmission; at present we have to do with the latter.

Now, if an individual were much confined to an apartment in which there were patients labouring under continued fever, breathing air loaded with the exhalations from such patients,—and if, after a time, the individual thus circumstanced were to be seized with the same disease, and others following after him subjected to the same influences, and sharing the same fate, with sufficient frequency and certainty to justify the conclusion that the one was the cause of the other,—and we were asked by what means or through what channel the system of the one became affected by the exhalations from the body of the other, we should, I think, have little hesitation in answering, that the matter exhaled from the bodies of the fever-patients entered the lungs of the healthy persons, along with the atmospheric air, and thus found entrance into the blood, where it accumulated until its amount was sufficient to impede the healthy functions of the body—that is, until fever was produced.

Again, if we were farther informed, that twenty previously healthy persons, from different localities, were similarly subjected to the influences above-mentioned, and that every one of these twenty persons was attacked by the disease, but that none of them were so until after an exposure of one or more weeks, some of them after a lapse of three months, and no two of them at precisely the same interval of time,—this would add confidence to our opinion, and we would say that the interval which elapsed between the first exposure and the seizure, marked the period during which the poison was accumulating in the blood, and that the difference, as regards length of interval, between exposure and attack, was an index as to the vigour or weakness of the different constitutions.

Our informant does not stop here, but tells us, that during the early period of the attack, and whilst it is at its height, the power to infect is not nearly so great as during the decline of the disease, and the advance towards convalescence. Here is another element in our belief, and we say, that whilst the disease is declining, and the patient recovering, the system is engaged in freeing itself of the poisonous matter, which is being evolved at the various emunctories of the body.

Now, these are not speculations, but carefully ascertained facts, and lead, I think, very conclusively to the belief, that in continued fever, the blood is primarily affected. I will not enter into the question, whether the constitution of the blood itself is changed by the action of the poison of fever, or, whether the blood merely serves as a vehicle for the conveyance of that poison in a free state to the various organs. This is a question unimportant as regards my present object; and moreover, we do not possess materials sufficient for its elucidation.

I will now proceed to a few practical deductions from, and illustrations of, the foregoing remarks.

Every practitioner who has seen much of continued fever in this country, is aware that the great danger he has to apprehend is the supervention of cerebral symptoms; here the intestinal follicular lesion is comparatively rare, and thoracic complication seldom

formidable;—the rock a-head he dreads is cerebral symptoms. Now, what I wish particularly to call attention to, is the fact, that when such symptoms do arise in the course of continued fever, they depend on a pathological cause, altogether distinct from that which is competent for the production of similar symptoms, when no fever exists—namely inflammation; and hence the remedies of inflammation are not always to be had recourse to, and never to the extent that would be advisable in primary encephalitis. The real cause of the head-symptoms would seem to be the effect which the poisoned or altered blood circulating in the brain produces on the functions of that organ; and strong evidence of the truth of this is to be found—first, in the progress of the disease, and secondly, in its morbid anatomy.

1st. In the progress of the disease, we find that the head-symptoms, during the early period of the attack, are confined to frontal headache and giddiness, with more or less of intolerance of light and sound; and as the disease advances, these conditions pass into great restlessness and sleeplessness, with active delirium, or it may be great torpor and drowsiness, with a wandering and confused state of mind when roused; and either of these forms may pass gradually into coma and death, or under more fortunate circumstances, into convalescence and recovery. All this would seem to mark the increasing influence of the poison on the blood, and through the blood, on the cerebral functions; and when this influence terminates short of death, we have another law of the action of poisons brought into play—namely, that after a time they lose their power over that particular system, and are discharged therefrom, leaving the individual in a fair way of recovery. Hence the wisdom of Cullen's statement,—that the proper object of treatment is "to obviate the tendency to death," well knowing that if the patient can be kept alive, and free from serious local lesion, for a sufficient time, the system will shake off the load of poison by which it is oppressed.

2nd. In the morbid anatomy of the brain in fatal cases of fever, from which ample proof has been obtained that there is no necessary connection whatever between the symptoms presented during life, and the morbid appearances discovered after death. I have examined the head in several cases, and one since I have been physician to the United Hospital, in this town, when death has taken place by way of coma supervening on the continued fever, without being able to discover any cerebral lesion at all proportionate to the symptoms, not anything more decided than slight sub-arachnoid effusion and perhaps, a drachm of fluid in the lateral ventricles. Dr. Alison, M. Andral, and Dr. Graves, have placed on record abundant evidence of the inability of morbid anatomy, to explain the cause of head-symptoms in continued fever. The following case in point is from Dr. Graves's "Clinical Medicine":—He says, "He was a young man of robust habit and apparently good constitution, and laboured under the ordinary form of maculated typhus. Shortly after his admission he was attacked with delirium, which was soon after followed by coma and death. Now, suppose you were called to see a patient, not labouring under typhus, but exhibiting a similar train of symptoms,—that is to say, violent delirium, accompanied by flushing of the face, suffusion of the eyes, headache, and a tendency to get out of bed,—in fact, a state of furious excitement, requiring the restraint of the strait waistcoat, what idea would you be likely to form of the condition of the brain? If a patient of this kind had no typhoid symptoms, you would certainly say that he was labouring under meningitis or cerebritis; and if the case proves fatal, you would naturally expect to find lesions of the brain fully sufficient to account for all his symptoms. And you would in all probability find extensive thickening of the membranes of the brain, with sub-arachnoid effusion, or you would discover softening, increased vascularity, and suppuration of the encephalic mass. But here, a man in fever exhibits all the symptoms of cerebral inflammation; the cerebral affection runs on to a fatal termination with great rapidity; he dies comatose. And what do we find on dissection? Doubtful signs of congestion, and no distinct evidence of inflammation; a slight opacity of the arachnoid at the base of the brain, and about a tea-spoonful of clear sub-arachnoid effusion." He then says, "This seems to prove that in the production of cerebral symptoms in typhus, some cause not to be recognised by the production of cerebral lesions, or in other words, something besides mere congestion or inflammation exists." And this brings us back to our starting point—namely, that this "something," which is neither inflammation nor congestion, is the effect of the poison of fever on the blood, rendering that fluid unfit for the support of the healthy functions of the brain.

It may be asked, why, in an attempt to fix on the blood as the starting point in fever, has no analysis of that fluid been submitted? The answer to this question is, simply, that no analysis has yet been made which has thrown any light on the matter, that is to say, the specific poison on which fever seems to depend has never been isolated. But this need not in the least surprise us, for there may be and doubtless are, many things in the blood which chemistry is unable to isolate,—urea for example. No chemist has yet succeeded in finding urea in healthy blood, yet if the function of the kidneys be arrested for a time, the presence of urea in the blood is easily demonstrated, showing that it does exist in healthy blood, although we are not able to find it. So again as regards sugar in the blood of diabetic patients. It was long before chemists succeeded in demonstrating the presence of sugar under such circumstances, and when this was done, it was by taking advantage of a well known

property of sugar—namely, fermentation. So that we are not at all justified in setting aside the evidence drawn from other sources, on the plea that organic chemistry has not succeeded in placing this poison before our eyes, for we must keep in mind, that whatever this poison may be, it is a matter with whose physical properties and chemical affinities we are wholly unacquainted, and that the only knowledge we possess concerning it, has been derived from a study of its effects on the living human body.

CASE OF PARTIAL AMPUTATION OF THE RIGHT FOOT.

By John Wickens West, L.A.C., M.R.C.S., &c.

Andrew Cobb, aged 25, by occupation a farmer, met with a severe accident to his right foot, August 20th, 1846. He had been engaged with his labourers at a thrashing machine, and his attention being suddenly attracted by one of his children approaching too near, he was put off his guard, and caught his foot in the machinery. It produced extensive laceration of the soft parts, and a comminuted fracture of all the phalanges of the toes excepting the little one, which was left entire. The metatarsal bones of the second and third toes were also fractured. The phalanges of the great and fourth toes were left in the machine, and those of the third merely hung by integuments. The bleeding at the time of the accident was considerable, but was timely arrested by a professional friend, who visited him in my absence.

On my arrival at his house about an hour afterwards, I found that the foot was merely bound up in a handkerchief, by the desire of the poor man, who was anxious for me to see him before an operation was performed. There had been no farther hæmorrhage, the artery, (popliteal,) being well secured by the tourniquet. On examination of the parts I found it quite impossible to save any of the toes, I therefore determined, in consultation with Dr. Crabb, to perform partial amputation of the foot; and as the soft parts beyond the toes were not much injured, I resolved to amputate as near to the seat of injury as possible, in order to retain for the poor fellow a useful limb. I commenced my incision on the dorsum of the foot, carrying it through the integuments in an oblique direction round the sole, thus securing a good flap. I then divided the tendons and other soft parts, and sawed through the centre of the metatarsal bones. The arteries were with some difficulty secured, especially the internal plantar; the outer being larger was more easily tied. The integuments were then brought in apposition, and retained by two ligatures, and the parts dressed with plaster and bandage. The man bore the operation remarkably well, and lost but little blood. Forty drops of the tincture of opium were given him shortly after, and I left him for the night.

21st. Visited him this morning, and found he had passed a restless night, and complained the bandage was too tight, and the stump painful. I slackened the bandage, and ordered cold water to be applied frequently. Pulse 96; tongue white.

Mist. Salinæ, oz. iss., quartis horis. Haust. Sennæ statim.

22nd. Has been more tranquil since yesterday, and got some sleep at intervals during the night. No hæmorrhage; bowels open; less feverish; pulse 90; tongue white.

23rd. Going on favourably, but the stump smells offensive, and is stiff and uncomfortable.

25th. At my visit this morning I removed the dressings, and found that partial adhesion had taken place; the stump discharged a thin fluid, but looked pretty healthy. I dressed the parts with soap-cerate plaster and bandage. Bowels open; pulse 96. To continue his medicine.

27th. On removing the bandage I found considerable discharge, very offensive and thick, and evident appearance of granulations. I ordered a bread poultice to be applied night and morning.

29th. The poultices have been continued since my last visit, and there is much improvement in the appearance of the parts, which are disposed to granulate freely. The ligatures are come away.

November 2nd. I omitted the poultices this morning, the parts looking so thoroughly healthy, and the granulations so exuberant, that I commenced applying caustic and dry lint, with straps of soap-plaster over.

3rd. The parts look healthy, and inclined to heal.

I continued the same treatment for three weeks, by which time the stump was completely healed, and the man was enabled, by the assistance of crutches, to get about.

December 12th. I visited him this morning and found he was able to put on an easy shoe, and could walk tolerably well with a stick.

I would remark, that I consider it far preferable, in all cases were it is possible, to amputate the foot at the centre of the metatarsal bones than to remove it at the articulation of those bones with the tarsal. The opening of joints, however small, is always attended by considerable irritation, and increases the sufferings of the patient.

Poole, December 26, 1846.

Hospital Reports.

WEST NORFOLK AND LYNN HOSPITAL.

COMPLICATED SURGICAL CASES AND OPERATIONS.

By Charles Cotton, M.D., F.R.C.S., &c.

(*Continued from page* 611, *of last Volume.*)

STRANGUATED HERNIA IN THE INGUINAL CANAL. (TWO DAYS.)

William Wicks, farm-labourer, aged 26, admitted at 10 p.m., October 27th, 1844. States that whilst unloading a cart of earth on the morning of the 25th a lump came down, which he was unable to return. He has been sick ever since, and the bowels have not acted. The surgeon who saw him having failed in the use of

the taxis, sent him to the Hospital, a distance of thirteen miles. There is a hard tense tumour, the size of an egg, in the left inguinal canal, scarcely protruding through the external ring; the testicle cannot be felt on the left side; the countenance anxious; pulse sharp and quick; frequent stercoraceous vomiting; complains much of pain in the belly and around the swelling. The taxis, warm bath, and bleeding proving ineffectual, and a tobacco enema, at the suggestion of Dr. Wayte, having been thrown up without avail, it was determined in consultation that an operation should at once be performed. The tumour was freely cut down upon throughout its whole length by Mr. Cotton, and its tendinous and fascial coverings divided, and the sac, dark and glistening, having the appearance of intestine, exposed; on opening which about two or three ounces of venous-looking blood burst forth from the wound. The strangulated contents proved to be chiefly omentum, much congested, and discoloured, with a knuckle of intestine situated high up at the internal ring, the seat of stricture. A blunt-pointed bistoury, carried flatly upon the finger, and afterwards turned upwards and outwards, relieved the stricture. The intestine was immediately returned, and the omentum readily followed. The edges of the wound were brought together by two sutures, and a compress was applied. The patient experienced immediate relief.

28th, 1 p.m. Pulse 78, soft and quiet; no pain nor sickness; bowels have not been moved. Haust. Magnes. Carb., Sodæ Muriatis, utrq. coch. minim. cum Syr. Papav., dr. ss. ex aqua statim.

9 p.m. Complains of a desire for stool; tongue clean; skin moist and warm; pulse 84; no peritoneal tension or tenderness. The injection of a castor oil, salt, and warm-water enema, in a few minutes brought away a large quantity of fæces and several scybala. To have panada diet, and a pill, with Opii, gr. ij., et Calom., gr. j., statim.

29th, 10 a.m. Passed a tolerable night, though occasionally griped; had a sparing feculent motion; there is a little pain and tenderness in the region of the wound, and the scrotum is œdematous and swollen; the pulse is quickened, 96. In every other respect he is quite comfortable. Let him have one-drachm doses of sulphate of magnesia in simple water every hour.

9 p.m. Bowels moved well three times; pulse 86, soft and compressible. Omitt. Magn. Sulph. Rept. Pil. Cal. et Opii.

30th, 10 a.m. Felt the wound uneasy during the night, and slept disturbedly, owing to frightful dreams. Is comfortable this morning. Bowels have not again acted; tongue covered with a creamy fur. Haust. Magn. Sulph., dr. ss., ex Aquæ Puræ oz. j., quartis horis. Sutures removed; wound dressed with simple-cerate, and covered over with a linseed poultice.

5 p.m. Has an inclination to pass water, but cannot make any. Catheter introduced, and sixteen ounces drawn off.

31st, 2 a.m. Complains of colic pains in the abdomen; eructations of flatus; nausea, and general uneasiness; bowels moved three times. A morphine draught was given by the house surgeon, and hot fomentations ordered to be applied.

10 a.m. Twenty ounces of urine drawn off by the catheter. On removing the poultice a dark sanious fluid issued from the wound. Let him have egg pudding, or good broth. Rept. haust. si opus sit.

November 1st. Wound continues to discharge a dark offensive fluid. A large slough came away this morning, pronounced to be the *glans testis*. Give a more generous diet and porter.

2nd, 2 a.m. Pain in the epigastrium; has vomited much bilious-like matter; the bowels have acted once. Morphine draught and fomentations to be repeated.

10 a.m. Pulse 72, weak; tongue furred; the wound discharges less and looks better. Give egg emulsion and farinaceous diet, with a little brandy or wine, but do not overload the stomach. R. Quinæ Sulph., gr. j.; Acid. Nitric. Dilut. m. x.; Syr. Aurantii, dr. j.; Magnes., dr. ss.; Aq. Cinnam., oz. iss. M. Fiat haust. omni tertia hora sumendus.

4th. In every respect improved. Mutton chop and half-pint of porter. Perg. in usu mist. ter in die tantum.

17th. Health good; bowels act daily; the wound slowly healing. Touch with Sulph. Cupri.

Dec. 1st. Dress the wound with Unguentum Resinæ. A hernia has made its appearance in the inguinal canal of the right side.

21st. The wound being sufficiently healed, let him have a double truss and be discharged. Cured.

STRANGULATED FEMORAL HERNIA, (FOUR DAYS.)

Sophia Linay, aged 37, of weak and delicate constitution, and the mother of eight children, admitted four p.m., May 28th, states that the swelling in the groin first appeared four days ago, during a harassing attack of diarrhœa, since which time she has suffered much pain, been frequently sick, and the bowels could not be moved; feels now pretty easy. She had been under medical treatment from the commencement of the attack without relief. On her admission, Mr. Whiting, in the absence of the surgeon of the week, applied the taxis, and again at eight p.m., and introduced O'Beirne's tube. No urgent symptoms being present the case was left till Mr. Cotton's arrival.

10. p.m. The patient feeling easy and disposed to sleep, said to be from the influence of opium given her previously to entering the hospital, a superficial examination only of a small diffused, firm, and unyielding tumour, receiving no impulse on coughing, situated in the right groin, and covered by a skin of a dusky-red colour, was made by Mr. Cotton, who expressed a doubt whether it might not be an enlarged gland swollen and inflamed from handling, and ordered a linseed poultice.

29th, 10 a.m. Has slept during the night, and taken some bread and milk for breakfast this morning. Has not felt pain nor been sick. The countenance is pallid and pinched; pulse 110, small; the belly is uneven and full, but not tender, and there is frequent borborygmus; flinches from pressure upon and around the swelling; bowels still obstinate. Consultation held. Applicentur tumori Hirud. viij., et postea fotus calidus. When the bleeding ceases, apply poultices smeared with Extr. Belladonnæ. Ol. Ricini, oz. j. statim et post horas ij. rept.

9. p.m. Much the same as in the morning, but seems weaker. An enema of croton oil and gruel thrown up,—returned unaccompanied by fœcal matter. Sumat Calom, gr. v., Opii Extr., gr. iss. hora somni.

30th, 11 a.m. Consultation. Had vomited very offensive stercoraceous matter this morning. The countenance is pale and anxious, breathing quickened, speaks in a whisper. It being decided that the patient should have the chance of an operation, Mr. Cotton, by an incision through the skin and agglutinated and infiltrated coverings of the swellling, laid bare the sac, on opening which, at the bottom, a small quantity of dark bloody fluid escaped, and a knuckle of black gangrenous intestine, the size of a walnut, was found attached nearly throughout by firm adhesions to the sac. These being carefully separated and the crural ring divided upwards and inwards by a blunt-ended bistoury guarded by the finger, the protruded bowel, after a short deliberation, was gently returned within the abdominal cavity. The patient complained of considerable pain, commenced straining, and the bowel was almost immediately forced back into the sac, and a considerable quantity of fluid feculent matter escaped from a small aperture where it had given way. The poor woman was placed in bed, in a position most likely to favour the discharge, which continued up to half-past three p.m., when she sank exhausted.

31st. The *post-mortem* examination shewed feeble adhesion of two or three convolutions and distension of the bowels, and considerable effusion into the peritoneal cavity, having a feculent odour. The strictured part proved to be about two-thirds of the tube of the ileum, which was lying loosely in the sac, black and gangrenous. The distinct ring of strangulation was marked by the peritoneal coat of the bowel alone remaining, through which a small rent had taken place, and the ring was found notched two or three lines deep upwards and inwards, and the peritoneum around dark and congested.

STRANGULATED INGUINO-SCROTAL HERNIA, (SEVEN DAYS.)

William Diver, a sailor, admitted November 4th, at half-past 9 p.m. Has always had a rupture on the right side, which he could partly return, until seven days ago, when it came down whilst doing duty at sea, since which he has had constant pain and sickness, and could not effect its reduction. The bowels had been unmoved. During the last twenty-four hours he has been under the care of a medical gentleman in the town, who kindly attended and explained the treatment which he had pursued. He had also taken medicine from the medical chest of the vessel. The belly is swollen and tender; the pulse small and weak; vomiting stercoraceous. There is a large swelling in the right groin, extending into the scrotum, receiving no impulse from coughing. Venesectio ad uncias xvj.; hot bath, and taxis, applied without avail.

Half-past 11 p.m. It being, in consultation with Dr. Wayte and Dr. De Mierre, considered right that the operation should be immediately performed, Mr. Cotton, in the presence also of Messrs. Allinson, Hale, Smythe, and Rackham, proceeded to lay bare the sac, by a free incision in the mesial line of the tumour, commencing high up, at its neck, and continuing it barely to the upper part of the scrotum. The seat of stricture was found at the internal ring, and divided by a blunt-ended bistoury, directed by the finger. About eighteen inches of intestine, exceedingly dark and chocolate-looking, were carefully drawn out of the scrotal cavity, and returned within the abdomen. Some blood escaped from the sac. The edges of the wound were brought together by sutures, and a compress and bandage applied. The man expressed himself as much relieved by the operation.

5th, 10 a.m. Passed a restless night, and was extremely prostrate. Vomited very offensive stercoraceous matter this morning at five o'clock. The pulse is weak, and small, 120; tongue brown; belly distended and tender; no stool. O'Beirne's tube passed up its full length, and an enema through it, which brought away a few rectal scybala; the patient got out to the night chair, but ineffectually. He gradually became more and more exhausted, and died at eight o'clock p.m.

6th. *Post-mortem* examination. Partial and feeble agglutination of the convolutions, and much flatulent distension of the bowels; the peritoneum dark and infiltrated about the seat of stricture; no effusion into its cavity. Upwards of twenty inches of ileum was found, of a dark-violet colour, pervious to air and fæces; a ring-like contraction marked the point of strangulation; the small bowel, as far as to the cæcum, was dark and congested. A portion of omentum, connected by a narrow neck to that of the belly, and surrounded by the cord, was found in the scrotal sac, much congested, and adherent to an enormous varicocele, which had almost obliterated the structure of the testicle by its pressure. Beneath the capsule of the left kidney several small hydatid-like vesicles, filled with dark serum, were found.

The examination shewed that strangulation had been sufficiently long to destroy the vitality of the intestines, and that the costiveness depended not on the bowel being impervious, but on death having destroyed its functions.

The above are the only operations for strangulated rupture which have taken place since the opening of the hospital, in 1835. It would be trite and common place to remark upon the propriety of early operation in the event of failure of the taxis after the warm bath and full bleeding; the rule I believe is almost invariable. Nevertheless, anomalous and masked cases, as many publications attest, may occur, and mar the intentions of the surgeon. A too precipitate resort to the knife, however, should equally be guarded against. In a case of scrotal rupture, with the usual symptoms of strangulation, which had obstinately resisted the bath, bleeding, and the taxis, I was about to operate, when the size of the protrusion, and the strength of the patient (a hale robust man,) induced me again to place him in the bath, and bleed to faintness, and to use gentle but continued manipulation. Fortunately, my perseverance was rewarded; the gut returned within the belly, the man

experienced instant ease, and recovered without a single uncomfortable symptom.

In another case, an out-patient of mine, (Pamment,) one of incarcerated scrotal hernia, with severe colicky symptoms and sickness, which had resisted the taxis, &c., occurring at night, *immediately after Diver's case*, and under the care of the house-surgeon, I was agreeably surprised to learn that after the administration of an anodyne draught the patient fell asleep for some hours, and that the gut receded almost spontaneously on his awaking.

No long time ago a medical friend in the country requested me to bring my hernia instruments and operate upon a strangulated femoral rupture of three days' standing. On my arrival I found the patient pallid, anxious, and vomiting; the belly full and tender, and an oval tumour, somewhat doubling over Poupart's ligament, existing in the left groin. Before operating I despairingly placed the woman topsy turvy, her head upon the floor, and the nates resting on the edge of of the bedstead, with the thighs closed, and drawn up towards the belly, and applied gentle pressure. In about a minute a commencing decrease of the swelling was perceived and the gut speedily afterwards receded within the abdomen. The patient got well without a bad symptom. A like happy occurrence happened under somewhat similar circumstances a few years ago in a case under the care of Mr. Johnson, of Wathington, Dr. Wayte, and myself.

Lynn, December 26, 1846.

(To be continued.)

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF WILLIAM SANDS COX, ESQ.

By Peter Hinckes Bird, one of the Resident Medical Officers.

(*Continued from page* 17.)

Case XVIII.

PERIOSTITIS.

Mary Anne Harris, aged 22, servant, admitted May 16th, 1846. She states that last Christmas she first perceived a pain in the right leg, which has gradually got worse ever since; had enjoyed pretty good health previously; is not aware that she ever received a blow on the part; thinks that exposure to cold caused it; is rather subject to cough; has never had rheumatism nor ulcerated sore throat, nor blotches on the skin, nor nodes; had leeches applied before she entered the hospital, without permanent benefit.

Present State.—Complains of pain, described as sharp, shooting, in the upper third of the right tibia; the pain is increased on pressure, is worse towards night and in wet weather; the pain extends slightly all down the bone, but is fixed in one spot, which may be covered by half-a-crown; the integument covering this spot is not so moveable as it should be; the skin feels rather hot; tongue coated; bowels confined; pulse feeble; does not sleep well at night; perspires a good deal in the night; no cough. R. Pil. Calom. Co. ij. hora somni sumend.

18th. Bowels open; feels rather better. R. Hydrarg. Chlor., gr. iv.; Confect., q s. Fiat. Pil. ij., hora somni sumend. Hab. Empl. Lyttæ, parti affectæ.

20th. Slept better last night; not in so much pain; blister rose well; bowels open.

27th. Pain not so bad in the morning, but much worse at night; thinks the pain is slightly lessened since the application of the blister; tongue clean; bowels open; health much improved. The part to which the blister was applied is quite healed. Ordered to have another blister applied.

June 2nd. The blister rose well, and afforded considerable relief to the pain; sleeps better.

10th. Blister has quite healed. Ordered to rub in frequently the following ointment:—R. Ung. Potass. Iodid. sæpe adhibend.

14th. Much the same as at last report; still complains of pain, but the pain is more circumscribed. Rep. Emp. Lyttæ.

26th. Blister healed. Has applied the ointment since with benefit.

July 1st. Complains still of slight pain. Rep. Emp. Lyttæ.

6th. Blister quite healed; pain nearly gone. Ordered to continue the use of the ointment.

20th. Discharged cured.

Case XIX.

PERIOSTITIS.

Joseph Marks, aged 54, travelling optician, admitted into the Queen's Hospital, under the care of Mr. Cox, on the 18th, of April 1846. He states that about twelve years ago, he first felt a pain in the left leg, accompanied with slight swelling; is not aware that he ever received a blow on the part; had an attack of syphilis about sixteen years ago; has never had it since; he took medicine for it which he believed contained mercury, as it made his mouth sore; he suffered shipwreck about six years ago off Boulogne. He states that he has been under medical treatment at various times without receiving any permanent benefit. About three months ago he took medicines, which made his gums sore. From the nature of his occupation he has been much exposed to the changes of the weather.

Present State.—He complains of much pain down the left tibia; pain described as sharp, shooting, is exacerbated towards night; the pain is diffused over the whole shaft of the tibia; the bone feels enlarged, uneven, and elevated in various places; the pain is increased on pressure, and by the weight of the bed-clothes; the skin covering the bone feels rather hot, and is described as being "*sore*;" it is covered by desquamations of the cuticle; the skin does not appear to be so moveable over the bone as that of the other leg; he can walk well without much uneasiness; pulse rather slow and small; tongue slightly coated; bowels open; sleeps but little; is prevented from doing so by the pain which feels like fire.

R. Pil. Hydrarg. Chlor., gr. x., alt. nocte sumend.

R. Sol. Magn. Carb., (Palmeri,) dr. iss ; omni mane.
R. Ung. Pot. Iodid., oz.ss, nocte maneque infricand.

21st. Slept well last night; complains of the pain which is very intense at night. Continue medicine.

26th. Sleep occasionally disturbed by the pain; skin not so sore; the bone appears to be smaller. Continue medicine.

30th. Sleeps much better after the pill which he takes at night; the pain prevents him from sleeping on the night when he does not take the pill; the integument not so sore; general health improved; the bone is decreased in size.

May 2nd. The pain is very intense at times in the night, especially when he is warm in bed; in other respects he is better. Continue medicine.

6th. The integument covering the bone is not so tender; he sleeps pretty soundly at times; the size of the bones appears rather less.

9th. Better, except in damp weather, when the pain is much more severe; it rained last night, and the pain was intense; the bone appears smaller; the integument is not so tender. Has taken a walk in the hospital garden.

16th. Much the same; the pain is very severe at times.

22nd. Since last report the weather has been very damp, and he has suffered severely from the "hot fiery pain," being obliged to throw all the clothes off the limb; last night, however, he slept pretty soundly. The integument is not painful on pressure.

24th. Was in very great pain last night, entirely preventing sleep; the integument covering the bone is hot and red, and considerably swelled; tongue rather coated; pulse 92. Omit the ointment. Apply six leeches to the limb,

27th. The leeches bled freely and afforded relief; the integument is not so hot nor painful on pressure; the pain, however, is not much relieved.

June 6th. Rather better; the warm weather we have had lately agrees with his complaint. Ordered to use fomentations, and to have a flannel bandage applied.

20th, Much the same; the pain is perhaps a little easier.

July 3rd. About the same; the pain, however, is not improved.

8th. Rather better; wishes to go home. Discharged relieved.

True syphilitic periostitis, (Case 19,) is more indolent in its progress than non-syphilitic periostitis (Case 18,) and the pain is always more severe at night than in the day, and is also increased in intensity during the damp weather. The pain in the non-syphilitic periostitis is not so intense as in the syphilitic variety. It is particularly disposed to occur on the central portions of the long cylindrical bones, and on such parts of the bones as are not covered by any great thickness of soft parts. In the two preceding cases the front surface of the tibia was the seat of this disease. Simple periostitis is most likely to be mistaken for venereal periostitis; but simple periostitis arises suddenly, and frequently disappears in a short time, without the use of mercury; and it appears to have more of the inflammatory character about it than usually belongs to the venereal variety. The best plan in all doubtful cases is to enquire particularly into the history of the case. We should consider the other symptoms which have previously existed, the order in which they have occurred, and the effect of any treatment that has been tried; and we must draw our conclusion by connecting the present symptoms with all the other information that can be collected. In case 18, no trace of the usual secondary symptoms, nor indeed of any syphilitic taint could be discovered, on the most careful inquiry; while in Case 19, the patient had suffered from a severe attack some time since.

It is the opinion of some that this disease is rarely produced in syphilis unless the patient has been using mercury. The late Dr. Hennen, a man of great observation and extensive experience, affirms that he had never seen more than two cases of nodes in patients who had not taken mercury. It is indeed a fact that we seldom meet with persons who have periosteal swellings unless they have been taking mercury; the patient, (Case 19,) had taken it for its cure; it would therefore seem, as if the action of mercury and the influence of syphilis together, had a share in bringing on these osseous swellings, for patients will take considerable quantities of mercury, and for an immense length of time, as in liver-complaints for instance, without nodes being ever produced.

In the treatment of venereal nodes, Dr. Colles looks to the operation of mercury for the final cure; but he observes, that until the mercury acts upon the system, the part should be repeatedly blistered; but speaking, however, of those nodes which are sometimes excited by the injudicious use of mercury, or by the irregularities of the patient, (of which the Case 19 I believe to be an instance,) which are more frequently seated in the tibia, and in which pain is more widely spread along the limb than in cases of purely syphilitic nodes, he says,—"patients under such circumstances are not fit subjects for the use of mercury.

Blisters, and the repeated application of the Unguentum Potassii Iodidi have been recommended in these cases; but in the preceding case they proved of very little use. Large doses of the Iodide of Potassium administered internally, and incision down to the affected bone, have sometimes proved effectual in these cases. In Case 19, however, the disease seems to have got such a hold on the bone, that it is very doubtful whether it will ever be cured without the removal of the limb, which was indeed proposed at some of the hospitals, after unsuccessful attempts to cure him; it was also proposed to the patient at this hospital, but to this the patient would not consent.

(To be continued.)

PROVINCIAL
Medical & Surgical Journal.
WEDNESDAY, JANUARY 27, 1847.

Three reform measures have been lately announced for the consideration of the Government and the Legislature,—Mr. Wakley's new Registration Bill, the Memorial of the Royal College of Physicians to the Home Secretary for an amended Charter, and a Memorial from the National Institute of Medicine, Surgery, and Midwifery, also addressed to the Home Secretary, for a Charter of Incorporation for the General Practitioners. Whatever views may be taken of any or all of these documents, it does not admit of question that the objects sought to be obtained are of the highest importance, and, that coming as they do, sanctioned with much consideration on the part of those from whom they emanate, and designed, as we believe they are, with singleness of purpose, for the benefit of the whole or of large and influential bodies of the profession, they are severally entitled to a calm and unbiassed examination.

We say they are entitled to a calm and unbiassed examination, irrespective of prejudice and party consideration, and we can conceive nothing more opposed to good feeling,—nothing more detrimental to the ultimate interests of the medical profession, than a hasty rejection of, or the manifestation of a spirit of undue hostility to, any one of these measures.

Mr. Wakley's Bill is in some respects a manifest improvement on his measure of the last Session of Parliament. It has evidently been carefully revised, and, as we think will be allowed by all, is well calculated for effecting the prominent object which it has in view, of marking at once by a broad line of distinction the genuine medical practitioner from the ignorant and unqualified pretender. Still the additional clauses will require to be carefully examined, and the bearing of the whole measure on the future prospects of a more comprehensive system of reform duly estimated, before it can receive the support of the profession or the sanction of the legislature. We shall not endeavour to prophecy the results of this examination, but content ourselves with expressing our belief, that, with some further modification in what may be termed the accessory details, the measure will be found highly advantageous, and we would commend it therefore to the candid consideration of our readers. Every medical man cannot be otherwise than interested in a measure which not only marks his *status* in the profession and his claims as a qualified practitioner, but extends to him the privilege of practising throughout the entire empire; and provides also more clearly than has hitherto been done, for the recognition of certain rights of exemption from public service, and other general privileges, which ought to be secured without the power of question, to every genuine medical practitioner, whatever may be his grade or denomination.

The Memorial of the College of Physicians for an amended Charter has for its objects the removal and prevention of certain abuses which are at present, or have lately been, dominant in that body—the annihilation of certain exclusive privileges conferred by Act of Parliament very inconsistent with the well-being of the College—the extension of its powers over the whole of England—the admission on liberal terms of all existing physicians, graduates of British Universities, who may not already be possessed of its licence—and the power of confering the degree of Doctor of Medicine on those, who, though not having enjoyed in early life the advantages of a collegiate education, may be found on due examination, possessed of sound practical knowledge, and every way fitted to be admitted into the College. We commend this memorial especially to the consideration of provincial physicians, whom it most concerns; but it is evidently for the benefit of medical science, as well as for the honour of this branch of the profession, that the anomalies and restrictions at present existing should be removed; and that while provision is made for the reception within the walls of the college of every competent physician, some check should be placed on the very indiscriminate manner in which, by the admission of some persons of doubtful qualification, and very questionable moral character, the licence of the College has lost much in the estimation of the profession.

The Memorial of the National Institute has mainly for its object the obtaining of a Charter of Incorporation for a large and influential class of the professsion, who, in consequence of the hurried and secret manner in which the existing Charter of the College of Surgeons was obtained by the Council, and forced upon the members of the College, have found themselves placed in a false position, as well as greatly aggrieved. Whether this or any other mode of remedying the act of injustice which has been perpetrated, and of giving to the general practitioner that *status* in the profession which he enjoys in the estimation of the public and of his professional brethren be adopted, there can be no question that the qualification for the practice of Medicine, Surgery and Obstetrics, which the general prac-

titioner requires, ought to be obtainable without the necessity of passing before so many different examining boards, and paying so many different inauguration fees. It is, moreover, but just and equitable, that the expressed wishes of so large a proportion of this branch of the profession as the National Institute embodies should receive unbiassed consideration, and if found consistent with a due regard to their own advantage and to the exigencies of the public service, should at once be acceded to. Under any circumstance no general measure of reform in which the interests of the general practitioners can be implicated ought to be allowed to pass without a distinct recognition of this body as constituting an independent branch of the profession.

Review.

Urinary Deposits, their Diagnosis, Pathology, and Therapeutical Indications. By GOLDING BIRD, A.M., M.D., F.R.S., Fellow of the Royal College of Physicians, &c., &c. Second Edition. London. 1846. Post 8vo., pp. 356.

The merits of Dr. Golding Bird's treatise on "Urinary Deposits," are well known to the profession, and this early call for a second edition is in itself an evidence of the work being justly appreciated. It may be well, however, to state, that although the short time which has elapsed since the publication of the former edition, precludes the idea of any change in the plan of the work, or any extensive additions to its contents, the later researches on the urine have been incorporated with the text. Among these we find the following notice of a new nitrogenized body, discovered by Pettenkofer, which, as Dr. Bird observes, must be regarded as playing a very important part in the physiology of the kidneys:—

"When an alcoholic solution of the extract of urine, previously neutralized by a little carbonate of soda, is mixed with a spirituous solution of chloride of zinc, an amorphous precipitate falls, followed by the slow deposition of minute crystals of a combination of chloride with this new body. Drain the whole on a filter, and pour on some boiling water, in which the crystals dissolve, and may be obtained, by evaporation, in yellowish quadrangular crystals, not very unlike lactate of zinc, for which they have been hitherto mistaken. On adding barytic water to a solution of these crystals, oxide of zinc and colouring matters are precipitated, whilst chloride of barium, with the new body, remain in solution. The solution being evaporated to dryness, is dejected in alcohol, acidulated with sulphuric acid, by which baryta is separated as a sulphate; and any excess of acid being got rid of by agitation with oxide of lead, the filtered fluid, by evaporation, leaves crystals of the new substance in a pure form.

"This body is neutral, has a bitter, pungent, saltish taste, and readily soluble in water and alcohol. Heated on platinum foil, it melts and burns slowly, evolving an odour of urine and ammonia. Chloride of zinc precipitates it from its watery solution. It contains 54.02 per cent. of nitrogen, and is said to exist in the proportion of five grains in 1000 of urine, exceeding one-third the weight of urea!"

The formula of this new body is said by Dr. Bird to differ "only in the proportions of the elements of water from that of uramil,"—a body which it is stated, "may be regarded as uric acid, in which the elements of urea are replaced by those of ammonia and water." This is, however, rather a loose mode of expressing the affinities of the two compounds. It might possibly be inferred from the passage as it stands, that the main difference between uramil and the new body, was from the presence of oxygen and hydrogen in the proportions necessary to form water, whereas a comparison of the formulæ for each shows a wide distinction.

	C.	N.	H.	O.
Uramil	8 +	3 +	5 +	6
New Body . . .	8 +	3 +	8 +	3

The approach to alloxan, an artificial result of the oxidation of uric acid is more evident. An addition of eight atoms of oxygen to Pettenkofer's formula being the equivalent to one atom of alloxan united with one atom of ammonia and one of water, and rendering probable Dr. Bird's suggestion that the new body may be a transition between uric acid and urea. We would however, observe, that the speculations connected with the formation and solution of these problems, and of the composition of many other organic quaternary compounds, however ingenious and captivating to the imagination, must be received with some degree of hesitation. Many of the analytical processes are difficult of execution, and the discrepancies in the methods pursued and results obtained by different experimentalists, render the value of these atomic symbols, by no means so mathematically precise as the algebraical appearance of the formulæ might lead us to anticipate.

In giving an account of cyanourine, a deposit of a dark blue, inodorous and tastless powder, first discovered by Braconnot, and since noticed by Spangenberg and others, Dr. Bird refers to a modification of blue colouring matter, recently described by Dr. Schmidt, as occasionally occurring in the urine of patients under hydropathic treatment, at Gräfenberg.

"The deposit consisted of ovoid globules, about one-third the size of a blood-corpuscle, and of a fine blue colour. It was partially soluble in hot ether and alcohol, forming blue solutions. Neither dilute sulphuric acid nor ammonia acted on it. Oxalic acid dissolved it, forming a blue solution. Potass, aided by heat, destroyed its colour. No uric acid could be detected."

Dr. Bird suggests that these blue pigments may arise

from some change in a protein compound; and instance the fact, that albumen when boiled with hydrochloric acid forms a bluish solution. They differ from indigo and Prussian-blue, both of which are occasionally found in urine, by characters sufficiently marked. May not the pigment observed in the urine of Gräfenberg patients be some form of altered blood-corpuscle? The continued transmission and transudation of large quantities of aqueous fluid through the blood-vessels and tissues can scarcely take place without the blood-corpuscles being acted on, as indeed the peculiar sodden anæmiated appearance of some of the water-drinkers at hydropathic establishments would seem to shew. The question is one deserving of further investigation, and may probably lead to curious results.

In the former edition the opinion as to the frequent occurrence of oxalate of lime in the urine was advanced, theauthor stating, as the result of his own experience, "that the *oxalate is of far more frequent occurrence in the urine* than the deposits of earthly phosphates. This statement has been since confirmed by the experience of provincial practitioners. Dr. Shearman, of Rotherham, states, and as Dr. Bird believes correctly, "that next to the urates small quantities of oxalate of lime are most frequently met with in the urine. Our readers will remember, in connection with this subject, the interesting observations on the influence of the rhubarb plant in producing oxaluria, published in the last volume of this Journal by Mr. Wilson, of Runcorn, and Mr. Bartrum, of Bath.

The discovery of cystine in the urine of chlorotic girls is an addition to our knowledge of this peculiar deposit, for which we are indebted to the research of Dr. Shearman, of Rotherham; and which, taken in connection with the probable deficiency of oxidation existing in chlorosis is, as Dr. Bird observes, a very interesting circumstance. In a communication addressed to Dr. Bird, the following particulars are mentioned by Dr. Shearman:—

"Some urine passed by a chlorotic girl, after being mixed with ammonia, and set aside in a white phial, evolved in a few days sufficient sulphuretted hydrogen to stain the glass black. When fresh, the urine had a very peculiar odour, and deposited a white sediment unaffected by acetic or hydrochloric acid, but soluble in ammonia. The solution left by evaporation six-sided laminæ, which in all their microscopical and optical properties resembled cystine. Two specimens of urine exhibiting these characters were passed by two sisters; a third was obtained from a girl belonging to another family."

A case was communicated by the same intelligent physician in this Journal, in which living animalcules were found in the human urine. Dr. Bird, in noticing the occurrences of vibriones in the urine, makes the following remarks:—

"Minute animalcules, belonging to the genus vibrio (V Lineola ?,) are occasionally developed in urine, so soon after passing, as to lead to the idea that their germs must have existed in the urine whilst in the bladder. All the urine in which I have found these minute creatures has been pale, neutral, of low specific gravity, and rapidly underwent the putrefactive fermentation.

"I have only met with these animalcules in the urine of persons in an excessively low and depressed state. In cases of syphilitic cachexia, where the prostration of the strength is extreme, and in mesenteric diseases, I have repeatedly found them abundantly developed with remarkable rapidity. They appeared in great abundance in the urine of a patient under my care in Guy's Hospital during the past summer. The subject of this case was a most miserable-looking young man, who entered the hospital half starved, and labouring under polydypsia, passing a very large quantity of urine of low specific gravity. He died of rapid phthisis. In a few weeks the urine became full of vibriones in active motion a few hours after being passed."

The animalcules observed by Dr. Shearman, were probably of the same description, but contrary to Dr. Bird's opinion, must have been generated in the urine previous to its evacuation from the bladder, as Dr. Shearman "*saw* the patient pass some urine into a *perfectly clear glass jar*," which he "*immediately examined*," and discovered the animalcules "enjoying themselves very briskly." Those in some urine passed in the evening, which speedily became alkaline died. Other specimens of urine remained the same as when passed for several days, and in these the animalculæ continued alive and active. The patient was a pale scrofulous-looking man, emaciated and feeble, and probably phthisical. In a patient whose case is reported by Mr. J. H. Stallard, of Leicester, in a subsequent number of the Journal "the animalculæ were present in urine directly obtained from the bladder, and died when decomposition had fairly set in." This patient was also greatly emaciated and laboured under chronic disease of long standing.

We cannot but recommend the study of Dr. Golding Bird's work to all who are called upon to be familiar with the important subjects of which it treats, in short, to every medical practitioner, but before concluding this notice we would direct attention to the laws laid down under the head of therapeutical considerations. They will be found in both editions, but they cannot be too strongly impressed on the practical physician, nor too prominently kept in his recollection.

"*Law 1st.* All therapeutical agents intended to reach the kidneys must either be in solution when administered, or capable of being dissolved in the fluids contained in the stomach or small intestines, after being swallowed."

"*Law 2nd.* Bodies intended to reach the kidneys must, to ensure their absorption, have their solutions so diluted as to be of considerably lower density than either the liquor sanguinis or serum of blood (*i.e.*, below 1.028.)"

"*Law* 3rd. If a sufficient quantity of water cannot be received into the small intestines, or the circuit through the portal system in the vena cava ascendens, or thence through the lungs and heart into the systemic circulation, be obstructed, or if there be excessive disorganization of the kidneys, the due secretion of urine cannot be effected."

This last proposition is deduced in an admirable paper by Dr. G. H. Barlow, published in the "Guy's Hospital Reports," and is quoted from them by Dr. Bird. The following conclusions are drawn from the consideration of these principles:—

"1. Whenever it is desirable to impregnate the urine with a salt, or to excite diuresis by a saline combination, it must be exhibited in solution, so diluted as to contain less than five per cent. of the remedy, or not more than about twenty-five grains in an ordinary draught. The absorption of the drug into the capillaries will be ensured by a copious draught of water, or any diluent, immediately after each dose.

"2. When the urine contains purpurine, or presents other evidence of portal obstruction, the diuretics or other remedies employed should be preceded or accompanied by the administration of mild mercurials, taraxacum, hydrochlorate of ammonia, or other cholitic remedies. By these means, or by local depletion, especially by leeches to the anus, the portal vessels will be unloaded, and a free passage obtained to the general circulation.

"3. In cases of valvular or other obstructions existing in the heart and large vessels, it is next to useless to endeavour to excite diuretic action, or appeal to the kidneys by remedies intended to be excreted by them. The best diuretic will in such cases be found in whatever tends to diminish the congested state of the vascular system, and to moderate the action of the heart, as digitalis, colchicum, and other sedatives with mild mercurials."

Proceedings of Societies.

BATH AND BRISTOL BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

Quarterly Meeting, Thursday, December 17th, 1846, Mr. ORMOND in the Chair.

WARTY EXCRESCENCES OF THE EYELIDS.

Mr. Estlin read a short memoir upon tumours, resembling warty excrescences, that grew upon the eyelids and face; he had been accustomed to designate them in the Annual Report of the Bristol Eye Dispensary as "Soft warts." They vary in size from a pin's head to a small hazle nut, their base not smaller than the projecting part, the white tumours shining through the skin. A minute aperture is observable in them, from which in the larger ones a white substance of the consistence of butter can be pressed out. Their contents cannot, however, be thus entirely evacuated, as each excrescence consists of a cluster of minute encysted tumours. When occurring elsewhere the larger tumour has usually near it several smaller. Many medical men are very familiar with them; others are unacquainted with them: they are chiefly seen at Ophthalmic Institutions. In the last ten years, during which time 20,941 patients attended the Bristol Eye Dispensary, eighty cases of these tumours occurred, being about eight in 1100 patients. The disease is probably that described by Mackenzie, as "Albuminous Tumour of the Eyelids," and unencysted. The contents, however, are proved by the microscope to be epithelial cells; and Mr. Estlin considers their investing membrane well entitled to the appellation of a cyst. Middlemore speaks of them as encysted tumours, arising from an enlargement of a mucous follicle. Guthrie gives them no particular name, but calls them encysted, and describes the appropriate treatment. Others regard them as of the nature of *molluscum*, the third genus of Willan's Tubercula. Some consider them as infectious. Mr. Estlin is inclined to this opinion, though he disbelieves the vulgar notion of the infectious character of the ordinary cuticular warts of children. They are probably diseased sebaceous follicles.

Their treatment was the principal object Mr. Estlin had in view in bringing this point of minor surgery before the meeting. He met with medical men who were teased by the management of these little tumours, and he formerly was so too. Lunar caustic, though freely applied, will often not get rid of them for weeks; nor will potassa fusa, unless so employed as to destroy the whole external surface of skin, which is firmly united to the tumour by vascular connection. This plan is tedious and painful. The most expeditious and least painful method is to slit them quite through with a lancet or cataract-knife, passed perpendicularly to their bases, and then forcibly to squeeze the separated halves, with the thumb-nails placed on the sound skin, till the contents are fairly turned out of their lodgment; the force required to do this will sometimes bruise the skin a little, but in two days the part is usually healed. The tumours when thus removed are found to be lobulated, appearing like miniature brains. If they resist considerable pressure, the loosened portion may be taken hold of with forceps, and thus the whole extracted. This practice may be employed when the tumours have begun to inflame or suppurate. Smaller ones usually disappear without treatment; their chief annoyance arises from the inflammation they occasion in the eye and lids. Children are the chief subjects of the affection.

Mr. Estlin has noticed that either the children with this malady bear pain with great composure, or the tumours possess little sensibility, for it is remarkable how little complaint is made, however roughly the tumours are treated. Specimens of two tumours which had been slit open and expressed were exhibited, as well as a drawing of their various sizes and appearances.

Dr. W. Budd had seen several cases of the disease, and had distinctly ascertained its propagation by contagion. He remembered particularly the case of a nurse, who, from nursing a child suffering under one,

had a crop of similar tumours appear on her temple, where the child occasionally laid its head. She then went home and conveyed the disease thither. Besides, it was not unusual to find them on the necks of those who nursed children affected with them. Whether the disease is a parasitic one, is a very difficult question. The cells composing it are larger than the epithelial cells, and of such extreme tenuity as to break very easily, but he had never been able to discover in them a nucleus. The principle of their contagion seemed to be the transplanting of these cells from one human being to another, which in its relation to cancerous deposits was very interesting. The pathological question is,—Are they composed of enlarged epithelium-cells, or of a parasitic nature? He drew the attention of the members to an excellent account of them by Dr. Paterson, in the *Edinburgh Journal*.

Fever.

Dr. W. Davies then read a paper on fever.*

Mr. Conway Edwards, from observations of the peculiar fœtor and foul state of the secretions, had been induced with much apparent success, to use a solution of chlorine, which he found corrected that state, though he by no means ascribed to the chlorine any specific effects on the virus of the disease.

Dr. Tunstall observed that the peculiar odour emitted in certain stages of the disease was given out through the perspiration.

Dr. W. Budd, in his many examinations of patients dead of fever, had not found the appearances nor results of inflammation; there was no fibrin in the brain, nor inflammatory exudation globules. The disease has all the characteristics of a poison, transmissible from one individual to another, which is often exemplified by an effected individual going into a community previously free of it, and from that single person it very frequently can be traced to have spread under circumstances often the most marked. In those cases characterised by drowsiness, the fluid in the cavities of the skull will be found loaded with urea, which circumstance has a direct influence on the treatment, which should then always be directed to the elimination of the secretion of the kidneys. Louis and Chomel had tried chlorine extensively, but had found it wholly useless; the first cases thus treated were benefitted, but the later derived no advantage from it, so that the result of their whole observation was that this gas is of no avail.

Intra-uterine dropsy.

Mr. King then narrated a case of dropsy occurring in a fœtus of eight months. The mother had borne six children, but did not menstruate between her first and her fifth pregnancies; was "unwell" once when she became pregnant with this child. Between the fifth and sixth months she became anasarcous, and at the time of parturition her abdomen and lower extremities were very large, tense, and hard. Some few days after labour her urine was not albuminous. The labour was natural but the child did not advance, though the pelvis was large, and the head of the child could be freely moved therein. The uterus was excited to action by two doses of ergot, and the child, with some difficulty, caused by the size of its body, brought down. At birth it measured round the waist sixteen inches and a half. The next day the serum had drained through the skin, partially denuded of its cuticle, and saturated the clothes in which it lay.

Mr. Soden mentioned a case of hæmorrhage of florid blood of some hour's duration, from the ear, after the removal of a small polypus, stopped by a short application of lint soaked in the tincture of matico.

Mr. Hetling gave the particulars and exhibited a specimen of rupture of the uterus.

Medullary sarcoma of the liver.

Dr. Cardew exhibited a case of medullary sarcoma of the left lobe of the liver. The man, aged 60, was admitted with a tumour in the epigastrium. Two months previously, while at work, he was seized with pain in the epigastrium,—which pain gradually increased. There was no jaundice nor vomiting, till a fortnight before death; the sickness was then controlled by salines, with prussic acid. On examination, the tumour consisted of curdy medullary matter, somewhat like cream, mixed with blood. There was an ulcerated opening into the cavity of the stomach, and a communication with the layers of the mesentery; the gall-bladder was filled with healthy bile; there was a mass of the same disease beneath the pylorus obstructing it; the right lobe of the liver was unaffected, so that the bile was eliminated, explaining the absence of jaundice.

Ovarian disease.

Mr. Norman narrated a singular case of ovarian disease. He was called to examine a lady, with all the symptoms of ovarian dropsy. The abdomen was large, tense, and fluctuation was most distinct. The swelling had begun at the right side, had lasted several months, and much impeded respiration. It was decided in consultation, that tapping would afford considerable relief; the trocar was passed, but no fluid came; and after clearing the canula, under the idea of some obstruction to the passage of the fluid, it was withdrawn without any fluid following it, or any aggravation of the symptoms. She became weaker, and after four or five weeks died. On *post-mortem* examination, the trocar was again passed, without giving issue to any fluid. On opening the abdomen, the cavity of the peritoneum was found full of a gelatinous substance like glue, which could be drawn out in long strings, and would not drop. This tenacious fluid could with difficulty be removed, though a bucket full was taken out. There was then found a cyst of the right ovary, not capable of holding a quarter of the fluid taken out. The cyst appeared to have burst, then lessened in size, while the secretion still went on from its lining membrane into the cavity of the abdomen, causing the sense of fluctuation.

Dr. Blackmore then gave the particulars of a case of nodulated ovarian disease. There could be felt

* This paper is given at length at page 36.

three distinct sacs fluctuating under the hand, and the fluid could be pressed from one cyst into the other. From the reduced and weak state of the patient, nothing but graduated pressure was recommended; after a while, a quart of thick puriform fluid was at once discharged from the vagina; discharges of such matter lasted for six weeks, while she gradually regained her flesh, lost her night sweats, hectic, &c.; and on her recovery, it was found that two of the cysts had disappeared, and that the smaller one alone remained.

SHEFFIELD MEDICAL SOCIETY.

Seventh Meeting.—December 23rd, 1846.

The PRESIDENT (Mr. TURTON,) in the Chair.

MENINGITIS.

Mr. Beckitt exhibited the brain of a man, aged 37, an ostler, who had laboured under epilepsy during the last eighteen years, and who died of subacute meningitis, of one week's duration. The brain was very heavy and firm; there was a cyst in the anterior part of the left hemisphere, and the choroid plexuses were large. He was, at the commencement of the attack, violently delirious, but effusion taking place, he became comatose and died in that state.

ANEURISMAL VARIX.

Mr. Thomas related the particulars of a case of aneurismal varix, at present under his care in the Infirmary. The man, aged 25, was closing the "sheep-foot blade" of a common pocket knife, by pressing it against his thigh, when it slipped and penetrated the limb, piercing the artery and vein midway between Poupart's ligament and the knee. Profuse hæmorrhage occurred, which was stopped by carefully applied pressure. A few weeks after the accident, he was brought to the Infirmary, at which time the limb was in a very atonic condition, exhibiting a number of unhealthy ulcers. The patient's general health was suffering. There was a very loud continuous bruit, resembling the *bruit de diable*, (increasing with each pulsation,) audible over the cicatrix, when the ear was four inches from the stethoscope, and extending along the whole course of the femoral artery. By the continued use of pressure, and a generous diet, with stimulants, his general health had been much improved, and the limb also, the ulcers having healed, but the continuous bruit is still very loud.

ABSCESS IN THE ABDOMEN.

Mr. Thomas then detailed a case of abscess of the abdominal parietes, which simulated distension of the urinary bladder, in a boy, aged 5. His health had been very good until about sixteen months ago, when an abscess formed in the perineum, which, on being opened, discharged a small quantity of pus, and soon healed. Last month he suffered from an attack of measles, and since then, a tumour formed in the hypogastrium; the scrotum became œdematous; has had great pain about the region of the bladder, and some difficulty in passing urine. His medical attendant suspected that there might be a calculus. On his admission into the Infirmary, he was in very great pain, and the hypogastric tumour completely resembled a distended bladder. Mr. Thomas finding an abscess existing in the perineum, opened it, and evacuated a considerable quantity of purulent matter, on which the hypogastric tumour entirely disappeared, and the patient is now rapidly recovering.

CANCRUM ORIS.

Mr. Micklethwait detailed the case of a child, aged 5, who suffered from hooping cough and tubular bronchitis, to whom he gave, in the space of ten days, Hydrarg. cum Creta., dr. j. The mouth became sore, without any flow of saliva. The soreness became confined to the left cheek, which soon presented the appearance of cancrum oris, which destroyed the cheek, opened the commissure of the lips, and destroyed the gums, teeth, and part of the tongue of that side, and terminated fatally in five days after the appearance of the gangrene. The child complained of excruciating pains of the hands and feet, which directly after death became very black. It had suffered from erysipelas of the same cheek three years ago, and ever since, that side had been less in size than the other.

Mr. Skinner mentioned two cases of cancrum oris, one of which was in a child to whom he had given mercury for pericarditis, and which recovered with some deformity; the other in a child who had measles, to whom no mercury was given, which terminated fatally.

[Some years ago, we had occasion to witness the occurrence of cancrum oris in connection with measles. Mercury had not been given in the cases alluded to, and one of the cases terminated fatally. ED.]

MEMORIAL OF THE NATIONAL INSTITUTE OF MEDICINE, SURGERY, & MIDWIFERY.

To the RIGHT HONOURABLE SIR GEORGE GREY, BARONET, *Her Majesty's Principal Secretary of State for the Home Department, &c., &c.*

The Memorial of the President, Vice-Presidents, and Council of the NATIONAL INSTITUTE OF MEDICINE, SURGERY, AND MIDWIFERY,

SHEWETH:—

That your Memorialists are Legally qualified Members of the Medical Profession and are General Practitioners of Medicine, Surgery, and Midwifery. That the National Institute is a voluntary Association of General Practitioners in Medicine, Surgery, and Midwifery; that your Memorialists have been duly elected the representative Council of the National Institute; and that they represent the opinions of above four thousand of the General Practitioners of England and Wales.

That Medicine, Surgery, and Midwifery, are departments of the same Profession; which Profession—in a scientific and educational point of view—is essentially one and indivisible; although, for the convenience of the Public, it has for a long time past consisted of three classes, viz.,—Physicians, practising Physic only; Surgeons, professing to practise Surgery only; and the

class of Practitioners of which your Memorialists constitute a large proportion, practising not only Physic and Surgery, but Midwifery also,—the last mentioned branch not being comprised in the range of practice generally undertaken by the members of either of the two former classes; and that this tripartite division of the practice of Medicine must continue to exist.

That, of every hundred Practitioners in this country, more than ninety belong to the class which your Memorialists represent; and that the greater number of the individuals constituting this numerous class are Legally and fully qualified as General Practitioners, by possessing a Licence to practise Medicine, and a Diploma, granted after an examination by the College of Surgeons, and qualifying them as Surgeons; although there are many exceptions to this rule, arising out of the anomalous state of the existing laws relating to Physic and Surgery.

That the General Practitioners have ever been, and still continue, the ordinary professional attendants of many members of the aristocracy, and of by far the greater proportion of the middle classes of society, and that they may be considered exclusively the Medical Advisers of the labouring population of this country; Physicians and Pure Surgeons acting as Consulting Practitioners, and their assistance being called for in cases of great emergency or difficulty arising in their respective departments; and that the Physician or the Pure Surgeon, or both, educated specially, and confining their practice to their respective departments, can never supersede the necessity which exists for a competent body of Medical Practitioners performing all the functions of the present class of General Practitioners, and educated to the highest practicable standard of qualification in the science and art of Medicine and Surgery.

That, in further illustration of the views of your Memorialists, your Memorialists regard the division of Medical Practice into distinct departments, as those of Physic and Surgery, presided over by special Institutions, and represented by different individuals, as an arrangement chiefly adapted for densely-populated and wealthy communities, and generally available by the rich only; and that, even in the Metropolis and in the larger towns, the General Practitioners must always constitute a majority of the Profession, while in country districts, the division of labour here indicated is totally impracticable; and your Memorialists have a thorough conviction that the well-being and comfort of every class in this great community are more or less dependent upon the competency and skill of this class of Practitioners; and that every defect in the Medical Institutions of the country, or any line of policy calculated to retard the progressive improvement of the General Practitioners, or to depress the standard of their qualification, or to diminish their scientific and practical attainments, or in any way to lower their status in society, has not only the effect of debasing the character of the Profession in this country, and of retarding the progress of Medical Science, but is fraught with incalculable, direct, and consecutive evils to society at large.

That, notwithstanding these considerations, the General Practitioners of Medicine, Surgery, and Midwifery are without a head or home amongst the Institutions of this country, and their position is at present most anomalous. They are acknowledged as Practitioners of Medicine alone, under the Apothecaries' Act, and they have been recognized as Practitioners of Surgery alone by the College of Surgeons: neither the Society of Apothecaries nor the College of Surgeons recognizes them as Practitioners of Medicine and Surgery—as one Profession. The *College of Physicians*, by its constitution and bye-laws, can have no sympathy with them, but a direct interest in maintaining the class in point of education, general and professional, and qualification to practise Medicine at as great a distance from the standard of that College as possible. Since the recent grant of a Charter to the *College of Surgeons*, that College has no sympathy with them, but has a direct interest in maintaining them in point of general and Professional education and qualification to practise Surgery at as great a distance as possible from the standard of qualification adopted for the fellowship of that College; and the College of Surgeons has, moreover, rendered it totally impracticable for any great proportion of them as General Practitioners—although possessing its own Diploma as Surgeons—ever to become Fellows of the College. The examinations instituted by the *Apothecaries' Society*, and their Certificate relating only to the practice of Medicine, obviously are inadequate to their present requirements; and yet, by a singular anomaly, this Society is the only body capable of giving a Legal title to practise.

Thus, although, as your Memorialists have shown, the General Practitioners constitue an indispensable professional body, which has been created by the customs and necessities of the community at large, and although they have progressively increased in numbers, and may now be estimated at many thousands, and have rapidly advanced in scientific and professional acquirements, and are possessed of great individual influence, they are unknown in a collective capacity; and legislative enactments have been attempted under the auspices of special Institutions, representing particular sections of the Profession, having interests peculiar to themselves, and diametrically opposed to those of the General Practitioners, without even an allusion to their existence. And your Memorialists most emphatically declare, that this anomalous state of the Profession operates as a direct infliction of the greatest evils upon society, especially by the systematic efforts which it engenders to depress the attainments, the character, and the status of the General Practitioners, and by arresting the progress and preventing the diffusion of knowledge in the great body of the Profession.

That, for these and other considerations, it has for a long time past been acknowledged by all parties, that the laws affecting the Medical Profession are most defective; and your Memorialists having been led to hope that the present Government may entertain the question of Medical Reform during the ensuing Session of Parliament, your Memorialists have felt it their duty respectfully to call the attention of the Government to

some of the more prominent circumstances relating to the class which they represent; and they have felt called upon to do so at the present moment more especially, as various attempts have been made from time to time to induce the Legislature to revise the said Laws; which attempts have failed, owing—according to the belief of your Memorialists—to the interests of the General Practitioners, as before recited, not having been duly recognized, and the Public welfare, as connected with the efficiency and respectability of the great mass of the Profession, having been accordingly entirely overlooked.

That, in the opinion of your Memorialists, the principle objects of Legislation in Medical affairs are, to promote the Public health, by securing the education of a sufficient number of persons for the practice of the Profession to meet the Medical and Surgical exigencies of the community, to ensure the advancement of Medical and Surgical knowledge and its general diffusion among all classes of the Profession, and to protect the rights and privileges of the Public, and of qualified Practitioners, by rendering it penal for unqualified persons to practise.

That different plans of Medical Reform having been suggested, but every attempt to effect such reform having hitherto proved abortive, and your Memorialists having stated truly what they believe to have been the chief cause of failure in these attempts, your Memorialists do not desire, upon the prseent occasion, further to press their own opinions upon the Government as to the principles, or to enter into the details of a measure of Medical Reform; but they are anxious to assure the Government that they would most gratefully accept of a settlement of this long-agitated question, from whatever source it may come, provided the interests of the General Practitioners were duly regarded in any measure that may be proposed, that efficient Medical and Surgical advice and attendance were secured for all classes of the community alike, and that proper encouragement were given to the advancement and diffusion of Medical and Surgical knowledge. At the same time, your Memorialists, aware, from their former experience, of the obstacles that are likely to be opposed to Legislation on the subject of Medical Reform, feel it their duty further to state that, although they would be willing to accept such a modification of either of the existing Institutions as should make it the head and home of the General Practitioners, giving the General Practitioners therein the means of securing a complete and efficient Medical and scientific education for their own class, yet they have a strong conviction that the objects of Medical Reform can only be certainly attained by the stablishment of a New College, distinct and different from either of the existing special Institutions, which shall embrace all persons possessed of any recognized qualification or license whatever, and in actual practice as General Practitioners at the time of its foundation, and shall provide for the education and qualification of all its future members; and further, your Memorialists cannot refrain from the remark, that the founding of a New College, in accordance with the spirit of the present age, is worthy the consideration of a paternal Government, and of a social reform Ministry; and that such a step would develop the energies of the Medical Profession in a manner and to an extent hitherto unprecedented in this country,—would maintain the respectability of the great mass of the Profession—would promote the science and art of Medicine and Surgery; and, inasmuch as the duties of the General Practitioners have an intimate connection with every Legislative proceeding bearing upon Public Hygiene and Sanatory improvement, would be one of the most direct and efficient means of ameliorating and preventing those social evils which are acknowledged to prevail to a lamentable extent in this highly civilized community.

That your Memorialists therefore pray that no Bill affecting the Medical Profession may be brought into Parliament which does not recognize the General Practitioners as a class, and provide for them an efficient control over the education of the members of that class, so that they may not only maintain the high standard of qualification which is now adopted, but that, by the cultivation of collateral sciences, they may promote the progressive improvement of the class, and thereby secure the true respectability of the great body of Practitioners in this country, to whose skill and judgment the limbs and lives of the mass of the population are entrusted.

Your Memorialists, in conclusion, have only respectfully to call the serious attention of the Right Honourable the Secretary of State, to the facts, opinions, and sentiments contained in this Memorial, in full confidence that matters of so much importance to the Profession of Medicine in this country, and to the Public interests, will meet with due consideration, and respectfully to request that an opportunity may be afforded them of giving, as they are prepared to give, the fullest explanation that may be required by a Deputation from their body, or otherwise, as may be most convenient.

(Signed,) ROBERT RAINEY PENNINGTON.
President.

General Retrospect.

PATHOLOGICAL CHEMISTRY.

ON THE CHARACTERS OF THE URINE, THE BLOOD, AND THE DROPSICAL EFFUSIONS IN ALBUMINURIA.

Heller has recently published a long memoir in which he has displayed the results of numerous researches relative to the pathological characters of the fluids, in albuminous nephritis. As this memoir gives a very complete insight into our knowledge on the subject, we think the following brief analysis may be acceptable to the readers of the *Provincial Journal*.

1. *Characters of the Urine.*—The progress of albuminous nephritis comprises three distinct periods, each of which is characterised by particular modifications in the urine. In the first or period of congestion, the secretion has a deep red colour, which is due to

the presence of blood, or at least to its colouring matters. Nevertheless the reaction is ordinarily acid, excepting blood be present in an unusual quantity. In the second or chronic stage of the disease, the urine is more pale, of a straw colour; while in the third period, it again contains blood, but it is at this time strongly alkaline, ammoniacal and fœtid. The secretion of urine is usually diminished during the whole course of the disease, excepting in some rare instances in the chronic stage, when its quantity is augmented.

In the first period, the urine, which is turbid, and high coloured, deposits either a whitish sediment, or a sediment which is coloured by the mixture of blood-globules; the super-natant liquor is at the same time clear and red. The presence of the perfect blood-globules is not, however, in all cases, the cause of the deep colour of the urine; it is sometimes due to the hæmatosin alone. The urine may be acid, neutral, or alkaline, and its specific gravity is always below par. In the second period, in which the urine is turbid but clear, the deposit is of a browner colour; in this period the reaction is acid. Later, the urine is often very pale, like thin whey, and deposits a light-coloured flocculent sediment; the urine at this time rapidly becomes ammoniacal; its specific gravity is, as before, diminished. In the latter periods the deposit is again reddish, from admixture of blood-globules; it is sometimes ammoniacal at the moment of excretion, but at all events soon becomes so; the specific gravity also rises.

In examining microscopically these various sediments, it is perceived that they are composed of two classes of materials, one comprehending those which are normally and constantly present in urinary deposits; the second, those which are accidentally present. The constant ingredients are:—1. The *Pavement epithelium*. This epithelium is always found in large quantity, especially at the commencement of the disease, at which time the deposit is almost entirely composed of it. The epithelial cells are not, however, of a natural figure, being rather round than oval, with very distinct nuclei.—2. The *Epithelium of the tubes of Bellini*. This epithelium is generally small in quantity at the commencement of the malady, wherein it differs from the former. It presents itself under the form of colourless canals, containing brownish nuclei of variable size. Considerable attention is required to detect the species of epithelium in the urinary deposit, as it is frequently so transparent as to elude observation.—3. Albuminous flocculi. (*Albumin pilze.*) These are very distinct, especially when the urine is alkaline, of various shapes and sizes, and resemble fragments of pearls.—4. *Mucus-globules*.—5. *Inflammatory globules*. These are found for the most part during the stage of congestion.—6. *Fatty globules*. Which exist principally in the chronic stages of the disease.

The accidental matters found in the urine of Bright's disease, are,—1. *Crystals of uric acid*, for the most part colourless and of a rhomboid figure.—2. *Urate of Ammonia*, which exists principally in the early stages.—3. *Pus*, generally seen in the early periods.—4. Crystals of *uro-glaucin*. These crystals are seldom seen in the urine at the time of excretion, but are often visible after it has stood for some time. They appear as a crystalline mass of an indistinct blue colour.—5. Crystals of *ammoniaco-magnesian phosphate*.—6. *Carbonate of ammonia*. Both these are peculiar to the last stages.

The re-action of the urine is almost always acid in this disease, which reaction Heller thinks is sometimes due to the uroxanthin, as it cannot always be accounted for by the presence of uric or hippuric acid. The effect of the presence of blood in any quantity is to render the urine alkaline. In the latter stages the alkalinity is due to the development of carbonate of ammonia.

The *specific gravity* is variable. In one instance observed by Heller, it ranged from 1.006 to 1.048. In order to gain a correct measure of the specific gravity, the albumen should be first coagulated by heat and afterwards separated by filter.

Among the different substances contained in the urine of albuminous nephritis, there are some which require special mention, and first of the *uroxanthin*. This substance presents itself in solution as a yellow colouring matter, and exists in considerable quantity, changing either immediately or more slowly to a violet colour, after the precipitation of albumen either by heat or nitric acid. *Albumen* is another constant ingredient, but varies greatly in quantity; sometimes it is scarcely to be recognised, at others the urine coagulates into a solid tremulous mass. At the close of the disease the albumen often nearly disappears. *Urea* is always present but in diminished quantity. The *salts* are less abundant than natural, not only absolutely but relatively.

2. *Characters of the Blood.*—The blood in this disease loses its density in a notable manner, in consequence of the loss of albumen. It, however, retains its natural appearance and coagulates perfectly. The serum is pale and of a low specific gravity. It contains urea in considerable quantity, but no biliary colouring matter. The fibrin and globules are not materially changed. The chief alteration therefore consists in a loss of albumen and the presence of urea; the latter condition, however, is not peculiar to the disease in question, but is observed also in cholera and in ischuria renalis.

3. *Characters of the Dropsical effusions.*—This fluid is of a pale yellow colour, alkaline, and of a low specific gravity. It contains albumen in small quantity, a circumstance which distinguishes it from the fluid of other forms of dropsy, in which, on the contrary, albumen is abundantly present. It never contains the colouring matter of the bile. By rest it deposits a small quantity of fibrin. It contains also epithelial cells, and salts in large quantity, and more particularly the chloride of sodium.

It is evident, therefore, from the above researches, that the constituents of the urine, blood, and serous effusions in albuminous nephritis preserve a certain definite relation. The water which should pass into the urine is found in the effusions; the albumen which is missed from the blood, is found in the urine,

and to a small amount in the effusions; the urea deficient in the urine is discovered in the blood; and lastly, the salts which are absent from the urine appear in the dropsical effusion. *(Archiv. für Physiolog. und Patholog. Chimie und Microscopie.* 1846. t. 2.

PATHOLOGY.

BRIGHT'S DISEASE OF THE KIDNEY.

The following conclusions, drawn by Dr. George Robinson, are the result of his researches on the pathology of Bright's disease:—

1. That the epithelial or secreting cells of the healthy kidney contain a certain quantity of oil; the proportion of which, under certain circumstances, and, within certain limits, may fluctuate considerably.

2. That it is an excessive increase of this fat leading to engorgement of the epithelial cells, and of the urinary tubes, which constitutes primarily and essentially Bright's disease of the kidney.

3. That the presence of albumen and blood in the urine, and the wasting of the tissue of the kidneys, are secondary phenomena, dependent on the mechanical pressure of the accumulated fat.

4. That, in the majority of cases, Bright's disease is associated with a similar fatty degeneration of the liver and arteries, and frequently of the valves of the heart; these diseases being related to each other as joint effects of one common constitutional cause.

5. That probably acute inflammatory dropsy, occurring in a person previously healthy, and the dropsy which occasionally supervenes upon scarlatina, have no necessary connection with Bright's disease of the kidney.

6. That most important evidence of the approach and presence of the renal disease may often be derived from a microscopical examination of the urine, in which will be found fat in unusual quantity; partly in the form of free oil globules, and partly contained in epithelial cells which have escaped from the urinary tubes.

7. That the insight which we have obtained into the peculiar change which the kidney undergoes in Bright's disease, and the knowledge we possess of the simultaneous occurrence of a similar change in other organs, may serve as important guides in the prevention and cure of the disease.—*Medico-Chirurgical Transactions, Vol.* 29.

PRACTICAL MEDICINE, &c.

DIAGNOSIS OF NEURALGIA AND NEURITIS.

Although in some cases the symptoms of these two affections of the nerve are so nearly similar, that it is difficult to distinguish at first sight the one from the other, the confusion will cease in general, if, instead of inquiring into the actual condition of the patient, our inquiries are directed to the prior history of the attack, its progress, and exciting cause. While, in fact, *neuralgia* is a very common affection, arising without appreciable cause, or from causes the most opposite in character, *neuritis* is a rare affection, and is determined by causes which are readily appreciated. In analyzing the best authenticated cases of neuritis, it will be found that, with the exception of some few cases, in which it followed parturition, neuritis has almost constantly been produced by physical lesions of the nerve,—such as wounds, punctures, contusions, ligature, compression by a tumour, &c.; in fact, neuritis is always, or nearly always, the result of mechanical injury, while neuralgia originates spontaneously, and depends upon a particular, and little understood, condition of the economy. But if it is sometimes possible and useful to establish this distinction in practice, especially in neuralgia and neuritis of recent date, it cannot be denied, that in a certain number of cases of chronic neuritis, the distinction becomes impossible; for although it has been ascertained that neuralgia of very old standing (thirty or forty years for example,) may have preserved its original character throughout, and yet left no traces of disease after death, it happens in the majority of cases, that under the influence of the repetition of the paroxysms, the texture of the nerve eventually becomes altered to such a degree, as to render it quite impossible to decide whether the inflammation has been secondary, or has depended upon an original neuritis. These cases shew the inutility of attempting a diagnosis in the chronic forms of the affections.—*Gazette Médicale de Paris*, No. 40, 1846.

THE URINE IN ASCITES.

In ascites, dependent on lesion of the liver, the urine is always more or less deeply coloured; whilst in renal ascites, (Bright's disease or otherwise,) the urine is white and colourless—(*Rayer.*) This characteristic condition of urine in ascites was perfectly known to the Arabian physicians.—*Monthly Journal of Medical Science*, December, 1846.

TINCTURE OF CANTHARIDES IN BRIGHT'S DISEASE.

This medicine, in the dose of from fifteen to twenty drops, "par pot de tisane," combined with the use of decoction of bark and chalybeates, is the remedy which has given the best results in the treatment of albuminous nephritis,—(Bright's Disease.) Many cases have already been cured by this treatment.—*Ibid.*

TREATMENT OF EPISTAXIS BY INSUFFLATIONS OF ALUM.

When hæmorrhage from the nasal cavities assumes a dangerous aspect, recourse is generally had to plugging, a measure both inconvenient and painful. M. Lecluyse has successfully employed means far more simple, and at the same time, according to his own account, more certain—namely, the insufflation by means of a quill of equal parts of powdered gum arabic and alum. In one case this succeeded after three repetitions; other means, and plugging among them, having entirely failed.—*Gazette des Hôpitaux*, Nov. 3, 1846.

SURGERY.

SALIVATION FROM CAUTERIZATION OF THE CERVIX UTERI WITH ACID NITRATE OF MERCURY.

M. Lisfranc has observed that the application of this form of mercury will produce salivation in about one case in two hundred; but the symptoms are not in general severe. In one case, however, a female, in the ward of St. Augustin, in the Hospital of La Pitié, a single cauterization produced an abundant and obstinate

ptyalism. [This fact is worthy of being remembered, not only as contradictory of the opinion generally entertained of the comparatively low vitality of the cervix uteri, but as a caution which should not be without value, in reference to the mode of treating uterine engorgements now much in vogue.]—*Gazette des Hôpitaux*, Octobre 17, 1846.

ON THE DIVISION OF THE TENDO ACHILLIS.

Professor Stromeyer has lately published the following propositions, in which he lays down the indications for, and the manner to proceed in, dividing the tendo Achillis:—

1. The tendo Achillis ought be divided with a small thin knife, with a sharp point, and slightly rounded, employing the subcutaneous section, and cutting from within to without, taking care to make but one puncture of the skin.

2. The tendon must be entirely cut through or the operation will be unsuccessful.

3. When other muscles or the plantar aponeurosis are retracted at the same time as the tendon, the former must always be divided before the latter.

4. After the operation the wound must be dressed with compresses, bound on with a bandage in the figure of eight.

5. With adults, on the fourth or fifth day after the operation, and with children, on the third or fourth, the first dressing must be removed, and if (as is often the case,) the wound is found to be healed, it must be opened again; this must never be done when there is great ecchymoses, or when the wound suppurates.

6. Before putting the foot in the machine for extension, the limb must be surrounded by a sound bandage, and some pads of cotton must be placed on all the parts that are to be submitted to great compression.

7. Extension must be proceeded with gradually and slowly, lessening it each time it gives pain to the patient.

8. The dressings must be removed if the patient suffers much and continued pain in the parts compressed, in order to avoid excoriations, erysipelas, or mortification of the tissues.

9. Immediately upon taking off the dressings the limb must be enveloped in wool.

10. It ought to be known, that all those who have had the tendo Achillis divided, have felt a sensation of cold and numbness, which is sometimes limited to the heel, sometimes extends over the whole limb. This sensation gradually diminishes, and generally disappears entirely by the sixth or eighth day.

11. The first day or the next morning after the operation, a viscid sweat of a disagreeable odour comes out on the foot, although the patient has never previously been subject to perspiration of the feet.

12. In placing the foot in the extension machine, it ought to be put in such a direction as to form a right angle with the leg; and this position ought to be maintained for eight days. After this period has elapsed, the limb must be enveloped in a circular bandage, and the patient must not be allowed to make any attempt to walk before the fourth week. Without this care, the limb will swell, the wound become irritated, and perhaps even the new tissue will give way.

13. It is impossible to name precisely the duration of the treatment. This must in some degree depend on the state of the patient, the degree of the deformity, and the extensibility of the articular ligaments.—*Ib.*. Nov. 10, 1846.

FORENSIC MEDICINE.

ON THE POSSIBILITY OF PRODUCING BURNS AFTER DEATH RESEMBLING THOSE PRODUCED DURING LIFE.

A reference to any work on Forensic Medicine will shew the reader that the distinction between burns inflicted prior to, and after death, is considered to be sufficiently precise. It would appear, however, from the experiments of M. Champouillon, that vesication which is considered to be characteristic of burns occurring during life, may be exactly imitated under certain circumstances after death. "It is not," says M. Champouillon, "by the immediate contact of a heated body, with an infiltrated limb, that it is possible to induce phlyctenæ in a corpse; we may in this manner induce vesication, it is true, but the elevated epidermis encloses air and not serosity." The number and size of the *vesications* according to him depend upon the temperature of the heated body, its distance from the skin, and the length of time the latter is submitted to its influence. "If," he adds, "a heated body, such as a red-hot bullet, be placed at a few centimetres distance from an anasarcous limb, no appearance of vesication is produced." If, on the contrary, it be placed within a convenient distance, one or more vesications are constantly produced. An attentive study of the causes which give rise to this phenomenon have shewn him that it is due to the effect of caloric upon an œdematous part,—a tissue charged with serosity. The action is no other than the rarefaction produced by the calorific body on the circumambient atmosphere, which rarefaction is proportioned to the degree of heat and the radiating power of the heated body. In anasarca the effused fluid diminishes the force with which the different laminæ of the cutaneous tissue cohere together; and it happens, therefore, that when by the rarefaction of the air near the heated body the atmospheric pressure is removed from the subjacent part of the corpse, the fluid accumulates there in virtue of a well-known physical law, and thus induce an elevation of the epidermis. M. Champouillon remarks, that these phlyctenæ do not appear instantaneously, but require the application of heat for six hours as a mean. As regards the red circle which Christison so strictly insists upon, as a proof of burning during life, Champouillon states that he has in no case failed to produce it in the corpse; but he allows, that however closely the red circle thus produced resembles that produced during life, the semblance is only superficial, and a difference is at once perceived by incising the skin. In the first case there is but a simple injection of the cutaneous capillaries; in the other there is evidence of vital re-action, in a concomitant extravasation of blood.

The results of the authors' researches tend to establish

that there is no sufficient *apparent* difference between burns before and burns after death, and thus the question can only be determined by a dissection of the skin, and that the distinction laid down by Christison fails in the case of an œdematous corpse.—(*Gazette Médicale de Paris*, No. 40. 1846.

OPIUM IN INFLAMMATION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Permit me to remove a misconception that occurs in Dr. Ranking's valuable paper on the employment of opium in inflammation. In regard to my views on that subject, he says, "The constipated bowels which Dr. Chambers, in the last number of your Journal, seems to regard as indncing the necessity for hesitation in the use of this medicine, I regard as of the least importance in the generality of inflammations." I did not apply that particular remark to its use in inflammation, nor did I for one moment wish to say that such an effect would contraindicate its use in any inflammation, in which it was otherwise indicated. But on the contrary, I look upon constipation as salutary in cases of enteric and peritoneal inflammation, and the purgative treatment of these diseaes to be both vicious in principle and bad in practice. In consequence of observing that the constipation attendant upon enteric inflammation yields *pari passu* with the removal of the inflammatory symptoms, it was supposed that the relief was owing to the soluble state of the bowels; whereas, I believe we must only regard this state as the consequence of the amendment in the inflammatory symptoms.

My observations on the constipating effects of opium were as follows:—"In reference to the employment of opium *generally*, I may remark, that the constipation which it causes, renders it obnoxious to some constitutions." There are several diseases not altogether of an inflammatory type in which the influence of opium is urgently required either to relieve pain, or to procure sleep. I would more particularly mention cases of common continued and irritative fevers, and cases of neuralgia. It frequently happens, however, that in consequence of the constipation which opium produces, its employment causes the patient as much discomfort as more than counterpoises whatever relief it may afford. In some cases this effect becomes at once apparent by the furred tongue, dry skin, and headach; in other cases the effects exhibit themselves by a long-continued derangement of the digestive function. If, then, it is possible to prevent all these effects without interfering with the physiological action of opium, is it not desirable to do so?

It would, indeed, be taking a very limited view of the matter to direct our attention merely to the constipation; we must look beyond the effect to the cause itself, which I believe to be an arrest of the biliary secretion; and, when we remember the influence which an arrest of secretion in so large a depurating organ as the liver must exercise over the quality of the blood, I consider its removal or prevention of the first importance. It appears to me that the coma of jaundice, to a certain extent, proves the correctness of my views of the subject.

In conclusion, allow me to say that I feel convinced that Dr. Ranking's misconception of my views was unintentional, and I should not have occupied your pages, only that the importance of the subject itself required it.

I am, Sir,

Your obedient servant,

RICHARD CHAMBERS, M.D.

Physician to the Essex and Colchester Hospital.

Colchester.

SPONGIO-PILINE.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Having seen Markwick's patent *Spongio-Piline* advertised, I ordered some of it to be procured, and feel bound in justice to state that, it has proved remarkably beneficial as well as comfortable to a patient of mine who was suffering severely from acute bursal rheumatism, affecting several of the joints. I ordered it to be steeped in a warm spirit-lotion and kept constantly applied, and am so entirely satisfied with the result that I venture to recommend its employment to the readers of your valuable Journal.

I have the honour to be, Sir,

Your obedient Servant,

J. C. BADELEY, M.D.

Chelmsford, Dec. 26, 1846.

INHALATION OF ÆTHER IN SURGICAL OPERATIONS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Having now administered the vapour of ether for the purpose of rendering surgical operations painless in a great number of cases, at our Metropolitan Hospitals and at my own private residence, with perfect success, by means of an apparatus invented by myself and Dr. Boott, and now manufactured by Mr. Hooper, of Pall-Mall, &c., permit me, if not encroaching too much on your valuable columns, briefly to state the appearance of the patient when under the influence of the vapour that indicates the proper time for the operation to commence.

As my own operations on the teeth have now become numerous and satisfactory to those medical men who daily witness them, I will not occupy the time of your readers by entering into details.

I am, Sir,

Your obedient servant,

JAMES ROBINSON.

7, Gower Street, Bedford Square,

January 18, 1847.

"At the commencement of the inhalation always allow the patient to inhale the vapour three or four times without closing the nose; the nose being

closed, observe carefully the appearance of the eye, the pupil of which will be found, in most cases, after about a minute's inhalation, to be considerably dilated; after eight or ten more inhalations the pupil will remain stationary and fixed for a period, varying from two to three seconds; it will then turn towards the upper eye-lid. This motion will be repeated several times. If the vapour be continued the pupil will be observed to turn under the eye-lid and remain *fixed*; three or four inhalations more and the operator can commence.

"In operations which are protracted and require any length of time, cut off the vapour by means of the stop-cock attached to the apparatus; permit the patient to breath the atmosphere through the nose five or six times; again let on the vapour, breathing alternately atmospheric air and the vapour of ether, at intervals of half a minute, until within two or three minutes of the completion of the operation, when the pipe, &c., can be removed with perfect safety."

J. ROBINSON.

7, Gower Street.

INHALATION OF ÆTHER IN SURGICAL OPERATIONS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The *Lancet* of January 9th, page 49, publishes a communication from a physician, reinforced by an opinion upon a supposed case, given by a Queen's Counsel, tending to diminish the value of the patent for the Letheon. Will you do me the favour to give publicity to the following answer to that communication?

I am, Sir,

Your obedient servant,

JAMES A. DORR.

London, 18, Duke Street, St. James's,
January 11, 1847.

Reply to the opinion of Queen's Council, published in the *Lancet*, January 9th, page 49.

1st. No counsel can give a client valuable, *or even safe*, advice, as to danger of infringement, who has not read the specification, and does not know the claim of the patent. The patent for the Letheon has been duly sealed, but the specification is not yet made public.

2nd. So far as the general principles of law enunciated go, they confirm the views of the patentees.

JAMES A. DORR.

[We question much, notwithstanding Mr. Dorr's letter, whether such a patent can be sustained, and certainly it ought not to be so. Any particular form of apparatus may without doubt, be made the property of the inventor; but the attempt to place restrictions on the mode of using a known medical agent by qualified medical practitioners, is as absurd, as its success would be mischievous.—ED.]

Medical Intelligence.

OPERATIONS PERFORMED UNDER THE INFLUENCE OF ÆTHER.

The following successful operations, performed under the influence of the inhalation of the vapour of sulphuric æther, have been reported since our last number:—

At Guy's Hospital, by Mr. Morgan, lithotomy, on a country lad; by Mr. Key, on a man aged 26, for strangulated scrotal hernia, with removal of a large mass of thickened omentum.

At King's College Hospital, by Mr. Fergusson, for phymosis, on a man aged 43; for abscess and fistula in ano, in a delicate female aged 26; passing a catheter through a tight stricture in the bulbous part of the urethra, in a man aged 32; removal of warts from the glans and prepuce, in a man aged 21.

At St. Thomas' Hospital, by Mr. Mackmurdo, the removal of a finger, from a child aged 6.

At the London Hospital, by Mr. Adams, amputation of the leg.

At Charing-Cross Hospital, by Mr. Hancock, removal of the nail from both great toes, in a man aged about 34.

At the Westminster Hospital, by Mr. Hale Thomson, removal of condylomatous growths from the labia, in a woman of middle age; for phymosis, in a young man.

At St. Georges's Hospital, by Mr. Johnson, amputation below the knee, in a young man.

At the Queen's Hospital, Birmingham, by Mr. Knowles, amputation of the leg, in a female.

At the Lynn Hospital, by Mr. Cotton, removal of cataract, in a female, and in an old man; of a cancerous tumour of the lip, in an old man.

Operations have also been successfully performed by Dr. Brett, (extraction of a cataract; ptosis;) by Mr. Lawrence, (removal of a tumour from the orbit;) by Mr. Partridge, of Birmingham, (strangulated hernia;) by Mr. Parker, of Liverpool, (for strabismus;) by Dr. J. C. Hall, of East Retford, (removal of a tumour;) by Mr. Rudkin, of Derby, (removal of a sequestrum of diseased bone from the leg;) &c., &c.

Mr. R. Lucas, a veterinary surgeon at Liverpool, has also performed an operation on a Newfoundland dog under the influence of æther vapour; the animal did not evince the slightest sign of suffering.

CAUSE OF DEATH IN STILL-BORN INFANTS.

Dr. King, of Sackville Street, has just submitted to the Medico-Chirurgical Society, an Essay "On the cause of Death of Infants Prematurally Still-born," wherein he insists, that death is not from asphyxia, as hitherto supposed, but from syncope; and proposes an entirely new practice, by which means the still-born infant will be of comparatively rare occurrence.

MEDICAL APPOINTMENTS.

M. Begin has been elected President of the Académie de Médécine, Paris, for the year 1847; M. Bouillaud has been elected Vice-President, and M. Métier, Secretary.

A Medical Lecturer has been appointed at Gonville and Caius College, Cambridge, to direct and superintend the studies of the Medical Students in the College.

Mr. Paget, Mr. McWhinnie, and Mr. W. Pennington, are candidates for the appointment of Assistant Surgeon to St. Bartholomew's Hospital, vacant in consequence of the resignation of the office of Surgeon, by Mr. Vincent.

Dr. Robert Lee has resigned the appointment of Physician Accoucheur to the Brownlow Street Lying-in-Hospital; and Mr. South that of Professor of Surgery to the Royal College of Surgeons.

ROYAL COLLEGE OF SURGEONS

Gentlemen admitted Members on Friday, January 22nd, 1847:—S. M. C. A. A. Smith; G. Goodlad; J. L. Johnston; E. D. Allinson; T. Bridgwater; A. G. Willington; H. G. Grayling; G. R. Skinner; C. H. Dunhill; J. Hyslop; W. E. Hughes; J. Beecroft; C. W. Wray; W. A. Salmon; W. Weston; W. F. Tomkins; T. H. Tanner.

ROYAL SOCIETY.

AWARD OF THE ROYAL MEDAL IN PHYSIOLOGY, FOR 1845.

The following important requisition for a Special General Meeting has been presented by Mr. Wharton Jones:—

We the undersigned, Fellows of the Royal Society of London for improving natural knowledge, do hereby, in conformity with the Statute, chap. xii., § 2, require a Special General Meeting of the Society to be convened, for the purpose of considering and determining on the legality of the circumstances under which the award of the Royal Medal in Physiology for 1845 was first recommended by the Physiological Committee, and under which it was actually made by the President and Council.

T. Wharton Jones.	W. F. Chambers.
James Copland.	John Webster.
Robert Lee.	James Clark.
Richard Bright.	Marshall Hall.
James R. Martin.	Robert E. Grant.

George Gulliver.

A COURSE OF LECTURES ON CLINICAL MEDICINE.

By W. R. Basham, M.D., Physician to the Westminster Hospital.

Lecture VI.

Case of Drunkard's Delirium, with pneumonia and bronchitis: History of the case; character of the delirium; stethoscopic signs; condition of the sputa; treatment: death; post-mortem appearances.—Tendency of drunkards to collapse; urgency of inflammatory symptoms, when supervening in such cases. Physical signs of pneumonia and bronchitis.—Pathological condition of pneumonia; cause of the rust-coloured sputa; progress of the disease.—Effects of bronchitis, complicated with pneumonia; discretion required in the treatment of such cases.

Gentlemen,—You have been present this day at the *post-mortem* examination of two cases of acute disease of the pulmonary organs, which, though they do not exhibit any uncommon features, are nevertheless of interest to those who are engaged in pathological studies; for every opportunity of making *post-mortem* examinations, affords us the valuable means of either confirming or disproving the diagnosis made during life; and what is still more important, we are presented with a view of the organic processes which constitute the disease, and learn the direction in which those organic changes proceed. The probable fatal or favourable issue of parallel cases is thus more easily determined, and the nature and direction of our therapeutical efforts more clearly defined.

R. H., aged 29, a green-grocer, had been drinking for the last three days, and during that time, in a continuous state of intoxication, was brought to the hospital, on the night of January 5th, at half-past twelve o'clock, by a neighbour. On admission into Burdett ward, he is reported to have presented all the symptoms of a case of *delirium tremens*. His manner was much excited; his answers to questions were hurried and indistinct; there was great trembling of the limbs, particularly of the hands; the tongue was tremulous, was quickly protruded, and as suddenly withdrawn; the mind rambling incoherently on a variety of subjects; the pupils were contracted, and the skin bedewed with a clammy moisture. He was ordered a dose of opium. In the morning, the report book states that he had been very restless all night; no sleep; much excitement and violence of manner; so much so, as to render necessary confinement by the strait waistcoat. Suffers from an exceedingly troublesome and suffocative cough, with frothy sputa, stained with blood. He had been ordered opiate draughts every hour, which he had taken up to the hour of the daily visit. A careful examination of the chest quickly decided that a different and very energetic plan of treatment was necessary. *Auscultation*:—The left side was duller on percussion than the right, and particularly on the mammary and lateral region; throughout the right side the resonance was clearer. On the left side, no respiratory vesicular murmur could be detected; bronchial respiration was everywhere, but especially in the mammary region laterally; respiratory murmur was also detected here, accompanied by some moist mucous gurgling. On the right side, the vesicular murmur was veiled by the presence of bronchial respiration and mucous rhonchi, in the large as well as the small tubes. The pulse was 120, full and elastic, round and compressible; the tongue moist, but furred; the respiration 48; frequent urgent cough; pupils contracted to a point; manner very restless, and much incoherence. With these physical signs there could be no doubt that acute inflammation of the bronchial mucous membrane existed, combined with pneumonia of the left side, probably at the root of the lung.

Here was a fearful combination of evils to contend against,—a drunkard, intoxicated for more than three days, continuously an habitual drinker, suffering from acute pulmonary inflammation. Such individuals will scarcely, under any circumstances, bear depletory measures; nevertheless, in such a case as this, they are imperatively required, and you must be prepared to treat them with the cupping scarificator, and antimony, calomel, and opium, in one hand, and with ammonia and other stimuli, if necessary, in the other. Accordingly this patient was cupped to twelve ounces between the shoulders, a large blister covered the left side of the thorax, and Hydrarg. Chloridi, gr. j.; Opii, gr. j.; Antim. Pot. Tart., gr. ¼, given every four hours. The pulse was directed to be watched; and if, after the cupping, it continued full and hard, a farther amount of blood was to be abstracted.

On the visit the next day, it was reported that the cupping had relieved the breathing and frequency of the cough, that the respiration had fallen from 48 to 40, and that the sputa were still frothy and sanguinolent. The pulse had improved in character after the cupping,

and was neither so full nor so hard as previously; the prognosis of the case, notwithstanding, still continued most unfavourable. At the afternoon visit the state of the chest was similar to that of yesterday; and owing to the blistered surface of the left side, could not be minutely examined. Bronchial respiration, with moist crepitations, were heard posteriorly on the left side; on the right side, mucous rhonchi were heard in each region. The sputa were copious, frothy, and of a more dusky dirty hue than yesterday; the tenacity was not very great, and they did not partake so much of the characteristics of pneumonia as of bronchitis. The pulse was 140, small and compressible; countenance anxious; eyes glazed; pupils contracted to a point; tongue moist; odour from the body offensive and cadaveric. The symptoms continued thus till the evening, when he changed, became comatose suddenly, the vital powers quickly failed, and he died at seven p.m.

Sectio cadaveris eighteen hours after death. Body well formed; limbs muscular, and rounded by subcutaneous fat. On opening the cavity of the chest the lungs did not collapse, but were adherent to the pleura costalis by firm attachments of fibrinous tissue; no evidence of the formation of recent plastic exudation: the right lung was dense and gorged, but crepitated throughout on pressure, and floated in water; no trace of fibrinous exudation could be detected in any part of this lung; when squeezed a white frothy fluid oozed out from innumerable openings of the more minute bronchi: the left lung crepitated only at its apex and the inferior margins; the central parts felt dense and carnified; its condition was such that it easily tore or broke down into a granular mass, and it did not float in water; this portion of the middle lobe was of a dark-brown, red, dirty colour, it constituted an example of lobular pneumonia in the second stage; the central portion of the hepatized mass was softer than the circumference, and appeared to be passing into the stage of purulent softening. Submitted to examination under the microscope granular corpuscles and blood-discs were alone observed; in some few of the former acetic acid developed central nuclei. The mucous membrane of the trachea exhibited a fine bright-red capillary injection; passing into the right bronchus the colour became more of a madder hue; and in the smaller ramifications of the tubes in this lung of a still more dusky appearance. The left bronchus exhibited much the same condition as the right; but the mucous membrane of the subdivisions had here become of a purple tinge, which colour was maintained even into the hepatized mass. The liver was much enlarged; its inferior margin extended to within a quarter of an inch of the umbilicus; a section exhibited a bright, sienna-orange colour; it had also a granular appearance; no evidence of portal congestion; under the microscope it presented innumerable fat vesicles; its weight was ninety-two ounces. The kidneys were healthy, presenting evidence of venous hyperæmia; right kidney weighed five ounces and a half; left kidney six ounces and a half. The brain presented no aspect of disease; its weight was forty-six ounces.

A prominent feature of interest in this case was the complication of acute pneumonia, with a condition which, if not strictly *delirium tremens*, was closely allied to it, being a state of great physical and constitutional disturbance brought on by the inordinate use of intoxicating liquors. The effect of alcoholic stimuli in excess, is at first to produce great cerebral excitement, with exaltation of the circulating powers; to this invariably succeeds a state of great prostration, and extending in some cases to collapse,—in fact, a failure of the powers and functions that have been thus unnaturally excited, is the usual characteristic of the drunkard's excess. Now, in the case under consideration, superadded to this dangerous tendency to prostration and collapse, were unequivocal symptoms of intense pulmonary inflammation, requiring the most energetic measures, and the unhesitating use of agents, which, without this pulmonary complication, the pre-existing state of the patient would most emphatically forbid. The prospect of a favourable issue was from the first extremely limited, for the pneumonia of drunkards is specially a fatal disease; they are proportionably more prone to the disease, and in them its progress is unusually rapid and uncontrollably fatal.

On approaching the bed-side of this patient on the morning after his admission, you witnessed his hurried and alarmed looks,—his restless, yet vacant gaze on those around his bed,—a certain amount of incoherence in his words, yet sufficiently conscious to protrude the tongue when asked; this organ quivering, furred, white and moist; the pupils contracted; and the hands, when released from the strait waistcoat which his violence rendered necessary, agitated and tremulous. He coughed frequently and had no sleep. You could not fail to recognize these as the expressive symptoms of the drunkard's disease; and inquiring no farther, you might have imagined that opium and ammoniacal stimuli were all that this case would require. But in the investigation of a case you must carry your inquiries beyond those limits which the eye merely reaches, the senses of hearing and of touch must lend their aid, and by them you must satisfy yourselves that no complication exists,—no lurking mischief in deep-seated organs, working insidiously to a fatal termination, while you have been busy only with those symptoms that lay on the surface, and are most easily and obviously detected. Here the respiratory movements of the chest were so much accelerated, that even without the stethoscope, pulmonary disease was to be suspected.

On carefully examining the chest, first by percussion, the left side was duller than the right, and this dulness was specially in the mammary and lateral region; on the application of the stethoscope over this spot, bronchial respiration, with a dry crepitating murmur was heard. The presence of bronchophony, and the total absence of any vesicular murmur, convinced me that the central portion and probably the root of the left lung was the seat of the inflammation. Superiorly and in the axilla of the left side, mucous rhonchi of small bubbles veiled all other respiratory sounds. The resonance of the right side was not much affected, but the mucous gurgling was heard in every region. This

physical state of the chest indicated the presence of broncho-pneumonia,—pneumonia situated probably at the root of the left lung, and an inflamed state of bronchial mucous membrane throughout its entire extent, the intensity being greatest in the smaller tubes; and I formed this opinion upon the absence of any moist gurgling of large bubbles being heard in the regions where the presence of secretion in the larger tubes is most readily detected—namely, posteriorly between the scapula, and anteriorly in the mammary region. The character of the sputa corroborated to a certain extent this diagnosis. They were copious and much was of a pure white frothy aspect, without much tenacity; but a portion was also frothy and somewhat rust-coloured, and this portion was more tenacious than the rest. Now, the pathological conditions on which these phenomena depend are these:—In that portion of the lung in which pneumonia exists, a retardation or stagnation of the blood in the arterial capillaries first takes place; what is the primary cause of the retardation or arrest to the even current of the capillary circulation, is not known or even likely to be. All that we can attain to is a knowledge of the conditions of any given phenomenon; the causes of those conditions are among the impenetrable mysteries of nature, and it is a useless expenditure of time speculating or guessing at it. All that we can state with certainty, is, that the earliest change observed in the capillary vessels of a part, the seat of inflammation, is a stagnation of the blood-corpuscles; their onward progress is arrested, and as an effect of, or concomitant with, this diminished motion, is the escape of a fibrinous spontaneously-coagulable fluid, which, filling the surrounding interstices of the tissue, consolidates the part, and gives firmness and solidity to what was previously elastic and extensible. In the pulmonary parenchyma this exudation not only fills the bronchial intercellular passages but the air-cells also. This accounts for the denseness and increased specific gravity of a portion of inflamed lung; and it also explains the presence of the dry crepitating sound on applying the ear to the region immediately over the seat of inflammation. This fibrinous exudation, the special product of capillary hyperæmia, contains dissolved in it much of the hæmaphein of the blood; its presence gives to the inflamed part the dark brown-red colour always observed in the first stage of pneumonia. A portion of this colouring matter, (hæmaphein,) dissolving and mixing with the bronchial mucus, tinges that fluid, a brown, red, or rust colour, and when expectorated presents us with the sputa so familiar in this disease. This constitutes the first stage of pneumonia. The next stage is the softening or breaking down into a purulent degeneration of this fibrinous deposit. In the case before us this condition had scarcely commenced, as the granular state and colour of the part testified, for as softening proceeds, all the hæmaphein of the blood is absorbed out, and a grey cheesy mass is left. When examined under the microscope only a few corpuscles that developed nuclei by the action of acetic acid were observed, the mass being composed of granular exudation corpuscles.

Now, it was not pneumonia only that the stethoscope detected; the other physical signs implied that the bronchial mucous membrane, especially in the smaller tubes, was in a state of inflammatory congestion. The *post-mortem* examination confirmed this, and exhibited to you morbid complications not unusual in the pneumonia of drunkards. The immediate cause of death in these cases is asphyxia, or death beginning at the lungs. The accumulated secretion of mucus in the air-tubes as effectually obstructs the passage of oxygen to the blood as any other asphyxiating agent; and when such conditions exist, coma usually for some hours precedes death. Venous blood continues to circulate till the patient dies literally "*poisoned by his own blood.*"

Many circumstances in this case co-operated to bring on the fatal issue. In the first place, the inordinate use of intoxicating drinks at all times tends to the creation of an inflammatory diathesis. Again, the season of the year, and the particular condition of the atmosphere—frosty, foggy, with a very elevated barometer, most unquestionably predispose the lungs to become the seat of inflammatory action. You daily witness, among both out and in-patients, how the season of the year predisposes to pulmonary disorders. Many circumstances co-operating, a series of morbid effects followed, from which it was not reasonable to expect that the patient could survive. I have already had occasion oftentimes to remark to you, that the co-existence of acute inflammatory action, with a general adynamic condition of the system at large, is by no means rare. It is this antagonistic state of things that for the most part renders inflammatory diseases fatal; for if the powers of the system be sufficient to permit those remedies to operate, which only can arrest the progress of inflammatory action, all may do well; but if the powers of life be low, these measures often add to the prostration, while they fail to check the advance of inflammation. Nevertheless, in such cases they must not be neglected; and indeed it is not unfrequently necessary to cup, blister, and give mercurials with one hand, while the system is supported by ammoniacal stimuli with the other.

The treatment of these cases requires great discretion. To bleed from the arm is not advisable; rapid subsidence of the vital powers often follows abstraction of blood from a vein. The most effectual and least hazardous mode of relief is by cupping between the shoulders, or over the affected side. Blistering is also desirable. Calomel, antimony, and opium, should be cautiously administered, and ammoniacal salines given at intervals the moment the pulse, by its softness, indicates their necessity.

I wish to direct your atttention to the case which died in the same ward on the same day,—one also of pulmonary disease; but an emphysematous state of the lungs, with chronic bronchitis, were the characters determined by the stethoscope, and at our next lecture I wish to point out to you some of the chief distinguishing features of that case.

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(*Fourth Series of Experimental Researches.*)

By William Addison, M.D., F.R.S., Malvern.

II. Animal Textures.

It may with great certainty be affirmed, that the blood contains the elements from which, in animal structures, the solid textures and the secretions are produced. Blood consists of a limpid fluid, holding in suspension a multitude of cells of two kinds; the one red, the other white or colourless; it may therefore with propriety be termed a *cellular or corpuscular fluid.* On its first discharge from the living vessels, blood is thin—that is to say, it drops like water, but it speedily becomes viscous or stringy, and then coagulates into a soft solid, which ultimately separates into two parts,—a red clot, and a yellow fluid serum. But blood, before it coagulates, frequently separates into two fluid portions; the uppermost colourless, and termed plasma, lymph, or liquor sanguinis, the lower red: both these portions coagulate, so that the solid clot is in part colourless, and in part red. The colourless part of the clot, which is uppermost, and formed by the coagulation of the plasma or lymph, is a coherent and elastic fibro-cellular texture, ordinarily termed the *buffy-coat;* it is usually depressed in the centre, with thin fibrous edges, and there is frequently a viscous, colourless, gelatinous mucus in the cup-like depression, that may be drawn out in strings like ordinary mucus.

The microscopic appearances in a film of blood *not* disposed to exhibit a colourless layer of lymph or plasma, are very different from those of a film of blood that *is* disposed to do so. In blood *not* disposed to exhibit a buffy-coat upon the clot, we see with the microscope numerous red corpuscles or cells, slightly cohering in strings and rolls, and a few colourless ones floating in a clear limpid fluid. In blood that *is* disposed to have a buffy-coat upon the clot, we see a much larger proportion of colourless cells, and multitudes of minute molecules floating with the red cells in the clear and limpid fluid; the red cells adhere more firmly to each other, and are congregated in larger and more irregular masses; and in the fluid, a network or tissue of interlaced filaments or fibrils is shortly observed to form. If a film of the colourless fluid, plasma, or lymph, be separately examined with the microscope, we find it mixed with innumerable colourless cells and isolated molecules; within the cells are a number of similar molecules, some of the cells containing much larger ones than the others; and when the coagulation commences, it is by the formation of fibres in the fluid. When water or a weak solution of potass is added to colourless blood-cells, they immediately begin to enlarge, gradually swell out to double their former size, and then burst open, discharging their contents, which consist of a viscous mass, mixed with molecules, and apparently identical in all its properties with natural or healthy mucus.

All the mucous secretions and the saliva contain colourless cells, which cannot be distinguished by any specific character from the colourless cells of the blood, and there appears no reason to doubt that the viscous matter of these secretions is an animal product elaborated in the interior of cells identical with those which are seen floating or mingled with it. Moreover, both mucus and saliva readily form fibrils or fibres when acted on by appropriate agents. These and several other well-known phenomena observable in the animal secretions may be treated of analogically, with a view to ascertain the origin of the fibrillating elements of the plasma, or lymph of blood, the element to which its coagulation into a coherent fibrous or fibro-corpuscular texture is due. Milk, among others, is a complex animal secretion, elaborated in the interior of cells or corpuscles, and set free by the thinning away, dissolution, or rupture of the cell-wall. The yolk of an egg is an analogous example, where the cells are large, and their walls so very thin, that it is with the utmost difficulty they can be touched in the gentlest manner without rupture. To the unassisted eye, milk appears as a homogeneous, white, opaque, fluid; through the microscope its white appearance and opacity are found to be owing to myriads of minute molecules,—and it is well known to contain an oily element or *butter*, a fibro-albuminous element or *curd*, and a limpid fluid or *whey*, and to the sum of each of these products every milk-cell contributes its quota.

The plasma, lymph, or colourless element, floating on the surface of newly-drawn blood, appears to the unassisted eye, when first seen, as a semi-transparent colourless fluid, gradually becoming viscous, and then fibrous and solid; and it is well known to contain, not only the solidifying fibrous, but a soluble albuminous and oily element. There are then the very same reasons for concluding that the fibrinous and albuminous elements of the blood, plasma, lymph, or liquor sanguinis, are derived from colourless cells similar to those found in it, as there are for concluding that the elements of milk, saliva, or any other complex animal product, are derived from cells; and the plasma or lymph of blood, therefore, is as much entitled to the term *secretion*,—to be considered as the products of cell-elaboration, as any of the other fluid or solid materials of the structure.

An abundance of colourless cells, filled with a viscous matter and molecules, are at all times discharged or thrown off, mixed with a viscid mucus, from the mucous membranes, and their numbers are increased upon the slightest irritation or inflammation. Similar cells are at all times discharged or thrown off

from all wounded and healing textures, where the process of reparation is going on—where new and conformable elements of growth are appearing, and where, therefore, the process of nutrition is normal. Similar cells are also discharged or thrown off from diseased textures, ulcers, and abscesses, from scrofulous joints, and from the cavities of the lung in consumption; in these latter instances more especially the cells have received the distinctive appellation of PUS.

Pus varies in consistency: it may be nearly solid, or quite fluid,—that is to say it may be solid enough not to drop like water, and in this state it is a *corpuscular texture*, analogous to the incoherent corpuscular textures of the lower forms of vegetation, and the green parenchyma of a leaf. Recently excreted pus displays under the microscope an abundance of colourless cells, the interior contents of which, in various states of elaboration, present various appearances. Old pus has a different microscopical aspect, which it is well should be remembered in considering the origin of tubercles, consisting chiefly of minute molecules and granular matter, resulting from the breaking down of the cell-walls. The cells or corpuscles of healthy or recently excreted pus vary in magnitude and appearance; active molecules are frequently visible in their interior, and when water, or a weak solution of potass is added to them, they swell, burst, and discharge their contents, consisting of a viscous matter mixed with molecules.

No wounded, irritated, or abraded texture, heals or ulcerates without the presence of a greater or less abundance of incoherent colourless cells; and there are no certain, specific, distinguishing marks between the colourless cells of blood, lymph and pus. When, therefore, a healing wound discharges pus, it can be regarded in no other light than as indicating a superabundance of nutritive cells, which from an actual excess in number, or some other cause, do not meet with the conditions required to make them deliver up their contents, and take part in the metamorphoses required for the reparation of the texture; but when an ulcerating wound (where there is no reparative process at all,) discharges pus, it would appear in that case, that all the cells from some inherent defect have lost the power of a conformable metamorphosis.

This explanation of the appearance of colourless cells, both in healing and ulcerating textures, implies in the former case a great excess of agents in the performance of a specific office or function—viz., the healing of the wound, and this so far from being, as might hastily be imagined, contrary to, is in fact quite in accordance with, the usual plan of nature as observed in other things, and in analagous instances. The pollen-cells of vegetables, for example, have an important and specific function, and in what apparently excessive abundance are they produced. Of the myriads of pollen-cells discharged from the anther, how few are actually expended in the fertilization of the embryo, compared with the myriads which *seem* to be wasted. In animals the analogous fact, too, may be produced in illustration. Again, in the repair of a fractured bone, what an apparent excess of nutritive material or *callus* is collected for the cure, which is subsequently removed when the fractured extremities have been united. Moreover, there are other facts in surgery pointing to the same conclusion; for healthy granulations, copiously discharging what is called healthy pus, heal rapidly by moderate and regulated pressure, which by diminishing the amount of blood flowing through the innumerable vessels of the young texture, diminishes also the amount of colourless cells, whereupon the quantity of pus diminishes, and the granulations then becoming covered with a coherent, fibrous, nonsecreting, instead of an incoherent, corpuscular, secreting texture, are said to cicatrize or heal. Colourless cells, therefore, in all cases of nutrition, appear as the primary and active agents, the results depending upon their metamorphosis.

From these facts and observations, and from others fully detailed in former researches, I draw these important conclusions:—

First, that in all living structures,—in all plants, and in all animals, the elements of growth and secretion,—that is to say, the peculiar and characteristic solid and fluid matters of the structure, are prepared or elaborated in the interior of minute vesicular bodies, variously termed corpuscles or cells, which may either be coherent, forming a strong or solid texture, or incoherent, forming a soft or brittle, and more or less a fluid one; and that the elaborated material, when set free by the opening or rupture of the cell-wall, undergoes ulterior changes, or metamorphoses, and either constitutes a part of the solid structure, or remaining fluid forms a secretion.

Secondly, that the incoherent cells of the parenchyma of the leaf are the primary elaborating cells of vegetables, and the incoherent cells of blood, the primary elaborating cells of animal structures. By the metamorphosis of the former, all the subsequent textnres and vegetable colours and secretions are produced; and by the metamorphosis of the latter, all the animal textures and secretions. The incoherent parenchymatous cells of the leaf are in all their stages stationary; and the air necessary to their respiratory functions passes to and fro around them by the motive power of heat. The incoherent protoplasma cells of blood flow in streams throughout the body, traversing in their course the walls of the coherent cellular and aeriferous texture of the lung, into and out of which the air passes by the motive power of muscles.

Thirdly, that the relations subsisting between animal textures or secretions, and the blood, are analogous to those subsisting between vegetable textures or secretions, and the leafy parenchyma; *and therefore that the*

law of the morphology of animal, must be analogous to that of vegetable, structure. In the latter instance, the doctrines based upon the law do not profess to give any reason why the parenchyma of one leaf differs from that of another,—why oil of peppermint is formed or secreted in one set of green cells, and prussic acid, opium, or bergamotte, in another; nor does it enter upon the question of the differences prevailing among the green granular cells of different parts of the same plants: on the contrary, the doctrines trace the form and mechanical properties, rather than the physiological function of the textures; so that the main features of morphology are only secondarily affected by differences and variations in secreted products. So likewise it appears to be in animal textures, that the morphology, in respect of form, is a branch of physiology sufficiently distinct from the morphology of secretion; and to admit, as is the case in plants, of a separate consideration.

"If we consider," says MOHL—and he is speaking of the cells of plants—"the place at which, in the interior of a cell, new cells are on the point of being formed, and at which the nuclei have already made their appearnace, we find that the future mother-cell contains *a viscous colourless mass, mixed with minute granules;* and since this viscous mass everywhere precedes the first solid formations, I trust it will be considered justifiable, if I propose to designate it by the word *protoplasma*, a term which recalls to mind its physiological function.*

Now it is evident, in the universally-existing process of cell elaboration, and whether the result be new cells, or permanent, cellular, or fibrous structure, or fluid secretion, that two distinct stages are recognised. *In the first*, the elaborating matter,—the *protoplasma* or primary element, (adopting the term proposed by MOHL,) is in progress of preparation within the cell, shut out from all extraneous or exterior agents, except those specially admitted through the cell-wall to assist in the elaboration. *In the second*, the elaborated matter having been set free by the opening or rupture of the cell-wall, undergoes its ulterior metamorphosis, subject to the action of new agents, which may influence conformably or unconformably, the completion of its permanent phase.

The liquor sanguinis or lymph which rises to the surface of newly-drawn blood is, if we adopt MOHL's term, the *protoplasma* of animal structures, and the buffy coat, is a *protuphasma*, a fibro-corpuscular texture, which, were it still within the vital influence of the whole structure, would, according to its analogies, become a secreting texture; and, moreover, the mucous or jelly-like matter often found in the depressed centre of the buffy coat is, in reality, the last change or secretion of this altering cell-texture.* "The glairy fluid termed mucus, being nothing more than an altered state of the fibrillating liquor sanguinis, the change from the one to the other being coeval with the changes within the cells. Hence, if we take the red portion of the buffed clot, and the red cells to represent blood, then the colourless layer of liquor-sanguinis (*the protoplasma,*) will represent the first remove from blood, and mucus or pus will be next; and it would appear, generally, that the nearer the cell is to, or the fewer the stages of its removal (*by morphological changes,*) from, the circulating current, the more nearly it resembles the colourless blood-corpuscle, and the more decidedly and visibly its fluid contents, when they escape, fibrillate; whereas, the further the cell is, or the greater the number of stages of its removal (*by morphological changes,*) from the circulating cells, the larger it is, and the less perfectly do its fluid contents fibrillate."†

"The blood can hardly be said to be organized, yet from the physical characters of coagulated fibrin, it is evident that while circulating in the body it holds a peculiarly endowed animal principle, (fibrin,) requiring only a moments rest to constitute solid, organized (I do not say vascular,) tissue. The texture, formation, cohesion, toughness, and elasticity, are all proofs of its organized nature; and it at once, without further aid or assistance, assumes all these properties, even after its removal from the body in venesection, or after death in its own vessels. There seems then, to be but one step between the microscopic capillaries and the fibrin of the blood; the former are minute fibrinous channels, the latter may (not inappropriately,) be termed *organized tissue, circulating with the blood.*" (*Medical Gazette*, March 26th, 1841.) These are sentiments expressed upwards of five years ago, and subsequent researches have confirmed *the idea* I then entertained. The term 'fluid texture,' may be objected to, nor can I contend for the congruity; but this does not alter the fact that the blood is a *cellular fluid*, and a clot of blood a *fibro-cellular* texture. The incoherency or brittleness of the lower portion of the clot is owing to the predominence of cells; the coherency and toughness of the upper part to the predominence of fibres.

---

* See MOHL's paper "On the Circulation of the Sap in Plants," in the "Annals and Magazine of Natural History," July, 1846. (Translated from the *Botanische Zeitung* for Jan. and Feb, 1846.) This author objects to the term *mucilage*, employed by Schleiden to designate this substance, as the term "vegetable mucilage," in the sense in which it is ordinarily used in chemical works, conveys a totally different meaning. The protoplasma of MOHL is termed "plastic element" in my "Researches," &c.

* *Prot-aphorismus*—the mucus having the same relation to the solid fibro-cellular texture that the *protoplasma* has to the incoherent cells of blood.

(To be continued.)

A CASE OF FATAL PHLEBITIS OF THE INFERIOR VENA CAVA, WITH REMARKS.

By J. Black, M.D.,

Senior Physician to the Manchester Union Hospital.

(Read at the Manchester Medical Society, Jan 6, 1846.)

Martha Wright, aged 26, unmarried, a domestic servant, but who, from the history of her habits, had led somewhat of a wandering and irregular life, was admitted on the 14th of August, 1846, into the Union Hospital, labouring under sub-acute rheumatism of the fibrous character, attended with simple derangement of the stomach and bowels. She was forthwith confined to bed, put upon low diet, and the Vinum Colchici, with Nitre in Julep of Acetate of Ammonia was prescribed for her.

On the 17th, she had, in addition to the above, which was then given in intermittent doses only, a pill every night, of calomel and antimonial powder, two grains of each, along with half a grain of opium.

On the 20th following, from her complaining of a pain in the right hypochondrium, she had a blister applied, and her pill was given in the morning as well as at night.

Under this treatment she was entirely relieved from her rheumatism; and on the 24th, the *colchicum mixture* was omitted, as well as her pill in the morning. She was then considered so far convalescent as to be permitted to leave her bed during the day. On the 27th, her pill at night was also omitted, from her gums becoming a little tainted by the mercury, and she had simply at bed-time, a small dose of *Dover's powder*, along with generous diet daily.

On the 4th of September, she was seized with the diarrhœa that, more or less, prevailed at that season as an epidemic, for which she took the *cretaceous mixture*, and from the complaint being rather persistent, she was again confined to bed, and on the 10th she had a pill every six hours, composed of the *diacetate of lead* and opium, which soon relieved the urgency of her symptoms.

Within the subsequent four days, her diarrhœa had entirely ceased, but along with its cessation, her abdomen began to be very tense and painful, and scarcely allowed the least pressure of the hand. In spite of large emollient poultices, and cooling saline medicines to act upon the kidneys, the swelling and tension continued to increase, with much restlessness and pain.

The case having by the 17th put on a very important and serious character, it was more strictly investigated, and the conclusion then arrived at was, that it was one of rapid and diffuse peritonitis, of an adynamic nature, with effusion into the cavity of the abdomen. This result was supposed to be occasioned by the quick stoppage of the diarrhœa, and the repellent effect of cold, while attempting to go about at the time she was constitutionally influenced by mercury; she was besides of a delicate frame of body, and I had some reasons to think that she had been previously intemperate. Her skin was at this stage warm throughout; her abdomen rather hot to the hand; there was thirst, little urine, the bowels were nearly regular; her tongue clean, but dryish, and her pulse small, frequent, and irregular; she, however, had no cough nor dyspnœa, nor could any *bruit* be heard in the region of the heart. I may also mention, that though her lower limbs were disposed to œdema since she came into the hospital, yet, at this period, the 17th, they had become much infiltrated up to the hips, though they retained their natural warmth. Considering the general debility of her system, it was not thought expedient to apply even leeches, but her saline diuretics were increased, along with half-ounce doses of the bitartrate of potass every second morning, and the constant application of emollient cataplasms and oily liniments.

By these means, the indications that were in view, of promoting a safe hydrocatharsis, and an increased flow of urine, were fulfilled, but there was no amelioration to the increasing tumefaction and tension of the abdomen, and to the swelling of the thighs and legs. In addition to the enlargement, which was early evidently owing to a fluid, from the very characteristic fluctuation elicited, there was by the 24th, observed all over the anterior aspect of the thorax and abdomen, well-marked enlargements of the epigastric and external mammary veins, both of which sets of vessels were perceived to inosculate freely and directly with each other.

This appearance in a few days became still more evident and interesting; the main branches became larger than swan-quills; and in passing the finger across the tract of many of them, a perceptible depression was felt, equal to the depth of half the cylinder of the respective veins, while they became full and distended below, and relaxed above the point of pressure. Some internal obstruction to the return of the venous blood to the heart from the lower parts of the body was now evident, but on what it depended was a problem not easy to resolve. No tumour had been detected nor even suspected in the abdomen during her period of diarrhœa, and nothing could be elicited from the chest or heart that could account for this sudden enlarged and vicarious venous circulation. The only conclusion that was come to at the time was, that the rapid effusion into the abdomen, along with the tensive resistance of the parietes, had acted as a counter pressure on the abdominal cava, and so impeded its transmission of the blood from the inferior parts of the body. With this view our medicines were continued, along with the Linimentum Hydrargyri et Linimentum Camphoræ, and calomel with a little opium was readministered on the 27th.

The disease, however, suffered no remission; for though the bowels acted freely when required, and the urine was kept to a normal amount of excretion, with a diminution of the tension and pain in the abdomen, yet the amount of effusion seemed to increase with more encroachment on the capacity of the thorax; the anastomosing veins continued enlarging, and the vital forces of the body and powers of the mind evidently began to give way under the incumbent affliction.

On the 8th of October, regular medicines were omitted,

and only extemporary anodynes and diuretic carminatives were given, along with strengthening broths, and a little gin daily. By these dietetic and negative medicinal measures, the patient struggled on till the 19th, when it was thought expedient to attempt to give her a little relief by paracentesis, which was performed by Dr. Francis, and sixteen pints of clear amber-coloured serum, without any flakes, were taken away, leaving a considerable quantity still unevacuated in the abdomen. Nothing but very temporary relief was the result of this measure, and our poor sufferer departed very quietly on the 21st of the month.

Post-mortem on the 23rd. The trunk, neck, and upper extremities of the corpse emaciated; abdomen not conspicuously enlarged, but discoloured; and the thighs and legs were much distended with serous infiltration. The large anastomosing veins on the anterior aspect of the body had nearly disappeared. The *lungs* were healthy, without pus or tubercles; the right lung adhered a little to the costæ, by an old band of adventitious membrane, while the left was posteriorly condensed, seemingly from moribund congestion. The heart was natural, only the right ventricle was less than the left; the valves were normal; the inner surface of the right auricle, and the corresponding ostium, with that of the base of the pulmonary arteries were much stained on the depending half by supposed imbibition; there were about four ounces of coloured red fluid in the cardiac sac. The *liver* was somewhat enlarged, obtuse at its margins, and slightly uneven over its peritoneal covering; on section it was very buffy, with the light-coloured element of the organ, or of the acini much hypertrophied, while the interlobular tissue was hyperæmiated. An encysted depôt of thick creamy pus, about two inches in diameter, was found in the posterior and upper part of the viscus, nearly on a line over the track of the inferior vena cava, and close to the hepatic vein; the sac seemed a little dense in its walls, and its interior was villous and soft. The *kidneys* were normal, but hyperæmiated, and a urinary cyst was in the lower end of the left one, and its dark sanguineous condition might have arisen from *post-mortem* gravitation, or from retrograde congestion from obstruction in the cava inferior. The *stomach* and *intestines* were much distended with gas, and had a dark grumous magma throughout the whole tube to the caput coli. The interior coat was thin not villous; in some places of the ileum it was uneven, but no ulcers nor cicatrices were observed. There were about four pints of yellowish limpid serum in the peritoneal cavity, but the lining membrane was natural, with the exception of some suffused and arborescent patches of capillary blood. The *bladder* was empty, and the *uterus* was natural, with the ovaria dense and enlarged.

The *vena cava inferior*, from the opening in the diaphragm to its junction, within a short space, with the iliac veins, was filled with irregular lymphous coagula and shreds, which adhered firmly to the inner coat of the vessel, and were connected with similar deposits in the azygos, renal and lumbar veins, but not to the same extent. Pus was found lodged in several of the upper parts of the vena cava inferior, but especially where it passed under the liver and just through the diaphragm. The right ovarian vein was much enlarged and somewhat tinged with blood; so was the left renal vein. The whole condition of the caval vein thus disclosed, very plainly showed that the returning amount of blood through the vessel must have been for some time previous to death much interfered with, if not totally obstructed.

In making my remarks upon this very interesting case, we may first consider the history of the patient before death, and I am sorry I have not kept a more detailed account of her consecutive complaints. We have next to exercise our pathological reasoning after inspection, as to the morbid sequences, and to see if we can trace anything like cause and effect to have existed among the several lesions.

Little or nothing definite was ascertained concerning our patient before admission, except that she had been leading a rather irregular life, and had been discarded by her near relatives, and from her own account she had for some time been complaining of the same ailment for which she was admitted—namely, rheumatism.

When first prescribed for, this disease had a sub-acute form, from which in about thirteen days she was wholly relieved, with her gums very slightly affected. Diarrhœa then set in in a very persistent form, and from the tormina and discharges there was some fear of ulceration, the remains of which, if it had existed, were not, however, observed on *inspection*. In a fortnight afterwards she was also relieved from this complaint, when the swelling, pain, and tension of the abdomen made their sudden and unexpected appearance. There was a probability that the diarrhœa was occasioned by an impression of cold while she was going about in the ward with her system not free from mercurial influence; but how this third and novel phase in her disease was occasioned was not so easily accounted for.

The first explosion of the entirely new symptoms suggested to us that we had to do with a case of sudden and diffuse peritonitis in a cachectic subject, attended with early effusion. In this view we thought ourselves supported by the pain and great tenderness on touching the abdomen, accompanied as they were with increased heat of skin, thirst, and a more frequent yet small and thready pulse. It was also assumed that the attack might have been accelerated, if not occasioned, in a constitution of so much mobility, by the cessation of the diarrhœa, a fuller diet with wine, and also having suffered a fresh accession of cold.

At this time she had long ceased to complain particularly of any pain in her right hypochondrium, for which a blister had been applied on the 20th of August. In the view then, of our patient being now affected with diffuse peritonitis, but occurring in a very asthenic subject, she was treated accordingly, but with no other result than a mitigation of pain and tenderness, while

the abdomen and lower extremities continued to swell, with increasing exhaustion of the whole system.

On observing the growing anastomoses and enlargement of the abdominal and mammary veins, our views of peritonitis became modified, for it was evident there was some obstruction in the abdomen to the due return of blood to the heart. This diversion of blood to the periphery of the trunk was at first attributed to the counter-pressure of the abdominal effusion, so rapidly generated under great resistance from the enclosing parietes, on the inferior cava and renal veins, and beyond this we had no farther data for speculation, as the patient had no ulcers nor varices in her legs, nor had she been for some time previously parturient. Our diagnosis at length became more doubtful, and I may say subverted, when on paracentesis the effused fluid was found limpid, without any shreds, flakes, or albuminous granules, while it was observed, subsequently to the operation, that the enlarged anastomosing vessels in the outward integuments did not in any marked degree subside. The case was thus left for an opportunity of nature revealing her own secrets and operations.

It will be seen from the record of the *inspection*, that the principal lesions worth notice were found in the purulent cyst of the liver, and in the vena cava, for the length of about six inches below the diaphragm, consisting of adherent shreds and plugs of lymph, along with coagula, extending into the renal and lumbar veins, and scattered depôts of pus, but especially where the caval vein just entered within the tendinous pillars of the diaphragm, and was joined by the hepatic veins. It was now evident that there were sufficient appearances in the state and contents of the vena cava to occasion most serious, if not total obstruction to the returning current of the blood, and that such obstruction was the cause of death. The important question, however, arises,—What occasioned this mortal affection of the vein? Was the lesion independent in its origin, uninfluenced by any previous affection of the bowels? or was it caused by sympathic phlogosis with, or on actual absorption of pus from, the cyst of pus in the liver? Considering how seldom veins do inflame or suppurate in the absence of injury to themselves or their branches, or of any focus of pus within reach of their circulation, and also considering the near allocation of the hepatic cyst to the portion of the vein that was most affected, which exhibited pus very similar to that in the cyst, it must be inferred that there was an intimate morbid connection; and the question is,—Which was the primary lesion that stood in the relation of cause to an effect? The density of the walls of the purulent cyst, and its appearance of some chronicity, compared with the filamentous and shreddy condition of the lymph, mixed with interrupted cysts, in the vein, and its purulent exudations of interspersed pus, which, at the upper part of the cava was to the extent of two to three teaspoonfuls, led to the inference, that the lesion of the vein was posterior to the formation of the purulent cyst in the liver, and that the phlebitis of the cava, was, moreover, either caused by pus being transmitted from the cyst by the hepatic veins, or by mere proximity of morbid action, as the two lesions were in very close collocation of parts.

It may be worth speculation to inquire, how was the purulent cyst occasioned? To fathom its initial steps, the inner surface of the ileum and colon was examined; but beyond what I have noted, no adequate causation could there be placed, whatever abrasion or mucous ulceration might once have existed.

In referring to the history of the case, we find that the patient had been complaining of a pain in the right hypochondrium, for which a blister was applied, on the 20th of August, being about nine weeks before her death. Though this pain was in a short time relieved, and was not specially complained of afterwards, there is every probability, from what was observed in the liver on inspection, that at that period the local phlogosis had commenced in this viscus, that eventually terminated in the purulent cyst. A remote consideration then arises, whether this topical affection of the liver was purely indigenous and original, or was owing to purulent metastasis from some of the other chylopoietic viscera. In the absence of any derangement of the stomach or bowels for the first six days she was in the hospital, beyond those of a simple character, (rheumatism being her chief complaint,) and failing of any exact knowledge of her state of health before admission, we are led to infer that the local phlogosis of the liver was idiopathic, and independent of any metastasis of purulent inflammation, or of absorption of pus from the intestines or other organs, through the medium of the vena portæ.

Taking then, this view of the primary state of the case, and that the purulent cyst in the liver had been slowly forming or of some standing, we have next to consider how the vena cava came to be affected; for the lesion of this vessel and its contents had every appearance of being acute and comparatively recent. The cyst being situate very closely to one of the large hepatic veins, though no ulcerous nor other communication was discovered between these cavities, and from the cyst also being in that part of the liver close to the notch for the vena cava, there seems little difficulty in attributing the lesion of the cava to either a venous absorption of pus from the cyst, or to a radiant irritation and inflammation from it. I should be inclined to assign the lesion of the great vein to the agency of purulent transmission and contamination. We know what disturbance and adynamic phenomema are occasioned by pus getting into the veins, either from purulent ulcers or wounds in the extremities, or from the iliac and hypogastric veins in

cases of puerperal phlebitis, and therefore I need not enlarge upon them,—suffice it to say, as far as our case is concerned, that that part of the vena cava opposite the hepatic veins seemed to have advanced most in the consequential lesions. It was at this spot and immediately below the diaphragm that the most perfect depôt of pus was found, while lower down the pus shaded off intermingled with lymphous shreds and clots, and thence coagula of blood intermixed with fibrinous shreds closely adhering to the inner coat, and irregularly filling the veins, terminated the lesion at the inferior part, to within a short space of the bifurcation.

How far death was specially occasioned by the toxic effect of the small quantity of pus that would thus likely find its way into the general circulation, or from the effects of the great abdominal effusion and œdema of the limbs on the vital and nutrient organs, it may not be easily absolutely to state. That the one lesion materially assisted the other in bringing on so rapidly the mortal event is very probable, as they were severally of a very grave nature. I should however, be inclined to attribute the acceleration of death more to the interruption of the vital and organic functions from the fluid pressure, conjoined with the very probable contamination of the systemic blood by even a small quantity of pus, than to the mere obstruction of the returning blood in the *vena cava*; for the vicarious and collateral circulation by the integumental vessels seemed to have been well established, and there are several instances on record, where this collateral circulation had been observed to go on for a much longer period, and where death was obviously ascertained to be caused by the direct effects of other diseases, as in the kidneys, though almost complete organic or chronic obstruction had been detected in the *vena cava inferior* after death.

Whichever of these several lesions had the greater share in anticipating the fatal issue, the case is very interesting, and as far as my researches have extended is a peculiar one. Instances of obstructed circulation in the cava inferior are recorded by Baillie, Reynaud, Wilson, and Cline;* and also by Rayer, Bright, Cruveilhier, and Dr. Barlow,† in all of which the obstruction was found to have been occasioned by either organic and impervious contraction of the coats of the vessel, fibrinous or bloody coagula, tumours of different kinds pressing on the cava, or from fungoid or medullary deposits in the vessel. I have not been able to meet with any case where *purulent* phlebitis was detected, nor any deposits of pus, either independent or metastatic. In looking over the details of these cases, it is curious to see that the blood in its return to the heart did not always work out for itself the same circuitous route, depending no doubt on the extent downwards of the more or less perfect occlusion of the inferior cava.

In Dr. Baillie's case the returning blood found its way to the heart by the lumbar and azygos veins.

In Mr. Wilson's case, as the obstruction had extended down to both sets of the iliacs, the recurrent blood had worked out a path through the vena pudica into the inferior mesenteric veins, and thence into the vena portæ, through the liver to the heart, a small portion of the cava inferior remaining pervious. Mr. Wilson refers to two similar cases in women dying after delivery.

In M. Reynaud's and Mr. Cline's cases, the vicarious circulation was effected by the abdominal and thoracic veins, as in the case now submitted to the profession.

Dr. Peacock relates a very interesting case in the last volume of the "Medico-Chirurgical Transactions," wherein the abdomen and limbs were much swelled for a month before death, and the patient died of hæmatemesis and hæmorrhage from the bowels. On inspection the liver was found free from disease, but it weighed only twenty-four ounces, though the subject, a female, was 47 years of age. The kidneys were in an advanced stage of degeneration. Coagula filled the cava, from the iliac veins to within an inch and a half from the diaphragm, and at this part the vein was contracted to an impervious ligamentous cord. The spermatic veins were large and firm, and the vena azygos, major and minor, were unusually large. The veins of the integuments of the abdomen were not enlarged, and Dr. Peacock saw no reason to suppose that the epigastric, thoracic, or mammary veins contributed to form collateral channels to the returning blood. No pus was anywhere discovered. He considered the disease inflammatory, but it was not easy to assign its period. He supposed death to have been occasioned by the renal disease.

In Hasse's "Pathological Anatomy," translated by Dr. Swaine, (Sydenham Society,) there is a very full exposition of phlebitis in general, as well as its affecting the *vena cava*; but nowhere is mention made of a case similar to the one above described, or as connected with purulent cysts in the liver. So far as rheumatism has any pathological agency or relation to the disease, there is notice quoted of a case where it seemed to give rise to phlebitis and obstruction in the hypogastric veins of a male. Hasse, however, observes, that "phlebitis from rheumatic affections is less prone to purulent formations than to plastic exudations," though in another part he says, "that in a great majority of instances phlebitis inevitably leads to suppuration."

I may here mention, though I have not noticed any analogous obstructions occurring in the vena cava superior, a very remarkable case of a patient that was presented by Dr. Carson, at the Medical Meeting at Newton, last summer,* after the patient being, with

* Edin. Med. and Surg. Journ., Vol. 43.
† Medico-Chir. Trans., 2nd Series, Vol. 10.

* *Provincial Medical and Surgical Journal*, August 5th, 1846.

much probability, cured of the pathognomonic symptoms, arising from obstruction in the upper cava. The disease seemed to have been well diagnosed, and at the period of exhibition, being twelve months after the sudden and painful attack, the man appeared in robust health. His complexion was, however, of a dark hue, and the veins of the forehead, neck, and upper extremities, and of the anterior trunk, were dilated, while veins as large as a swan-quill proceeded over the anterior part of the chest, to a tortuous cluster of vessels in the epigastrium. From this cluster also ran large veins to the groin, and the course of the blood in all these vessels was, from above downwards, the very reverse to what obtained in our fatal case.

I am afraid that I have enlarged too much upon this single case, but from its variety, if not from its being nearly unique in its special origin, it is presumed it may be somewhat interesting, as shewing the powerful yet ineffectual struggles of nature to overcome one of the most serious spontaneous lesions that can occur in the body. It is also one of those cases that shews us, that the difficulty of a special diagnosis is equalled by the inefficacy of our means of cure or much relief, even provided such lesions were as palpable as they are obscure.

CASE OF HEPATIC ABSCESS COMMUNICATING WITH THE LUNGS.

By John Barclay, M.D., Member of the Royal College of Physicians, Leicester.

A.B., aged 41, Dissenting Minister at a village in this county, first applied to me on the 18th October, 1845. His complexion was dark, his form spare, and his look cachectic. His general health had been good, and he then complained of slight abdominal pain, which was relieved by gentle stimulant tonics. On the 15th of November, he was brought to me much worse. He had had severe rigors and had afterwards spit up half a pint of matter.

Nov. 21st. I saw him at home with the surgeon who had attended him. The auscultatory signs were quite natural; there was no dulness, no resonance of voice, no moist sounds anywhere to be heard, and both lungs expanded properly. He continued to expectorate a very large quantity of most offensive pus, which came up in mouthfuls. From all the symptoms, I formed a diagnosis of an abscess in the liver, communicating with the lungs through the diaphragm. I put him on a tonic plan of treatment, and bid him hope, as it was *not* "consumption."

December 11th. I saw him again at home. The emaciation was now extreme; the expectoration continued in large quantity, and most offensive. Though his friends had all given him up, I continued firm in a favourable prognosis, as by another carefully-conducted examination I could detect no lesion of the lung; and from this day he began to improve. He rapidly gained flesh and strength, so that in April and May, 1846, he was able to resume his duties and preached frequently with no inconvenience.

On the 30th of June he came to tell me that while stooping in his garden some days previously, a mouthful of blood had come up, and his cough had returned.

July 10th. He now expectorated muco-purulent matter of little or no fœtor; the pulse was more rapid and emaciation proceeded rapidly.

15th. He had slightly improved under the tonic treatment again.

August 10th. I saw him with another practitioner, who had occasionally visited him. We could discover nothing amiss in the lungs, and he coincided with my diagnosis.

24th. Still very ill; still nothing to be detected in the lungs.

September 3rd. Since last visit he had complained much of pain in the lower part of the right side, on which he could not lie; decubitus on the back; the cough was very troublesome; the expectoration purulent and fetid. The lower part of the right side of the chest was now decidedly dull on percussion; the expiratory murmur very rough, loud, interrupted by occasional large moist sounds. The voice anteriorly at that part was tubular and snuffling; pulse 90; respirations 36; skin cool; emaciation great; appetite good.

7th. I put him under a course of the iodide of iron.

16th. A little better, I could detect no moist sounds in the lung.

October 6th. Very much improved; getting round, he hoped quite, as he had done last year. He still coughed and the expectoration became fetid after standing some time.

31st. He came to ask my permission to resume his duties, as he felt quite well. I withheld it however, and he continued to improve throughout November and the first weeks of December.

On the 4th, and again on the 6th of January, he had severe rigors, and on the 8th I found him much worse, in bed, with acute pain at the superior part of the abdomen; the cough very troublesome; much exhaustion and debility; pulse irritable, small and weak.

12th. I found him jaundiced all over; urine dark; stools scanty; cough very bad, and expectoration muco-purulent; much dulness and large moist sounds at lower part of right side.

16th. Peritoneal inflammation had evidently now arisen, and the pain was most intense on the left side.

17th. Blistering had relieved the pain considerably, but he was evidently sinking, and unable to expectorate from weakness. He died on the 18th.

Post-mortem examination thirty hours after death. Body jaundiced deeply, and considerably emaciated; the pleuræ of the left side were slightly adherent, but the lung was healthy; the heart was pushed over considerably to the right side; the upper lobe of the right lung was healthy, but the pleuræ were adherent in their whole extent; the middle and lower lobes were very much condensed and contracted, adhering to the ribs by very old strong fibrous connections, and quite

incorporated with the diaphragm. When cut into at the lower part it appeared a homogeneous mass of condensed cellular tissue, in which the bronchi were seen filled with a sanious purulent matter. In contact with the muscular tissue of the diaphragm were several irregular ulcerated cavities filled with the same sanious pus. The upper surface of the liver was adherent in its whole extent to the diaphragm; in some places the adhesions seemed recent, but particularly at the spot corresponding to the abscesses in the lung, they were very firm, and evidently of long standing. When cut into the substance of the viscus was seen to be quite infiltrated with numerous small and some large abscesses, filled with unhealthy fetid pus; it was considerably enlarged and very convex. The peritoneal inflammation had extended to the spleen, nearly the whole surface of which was covered with recently-exuded lymph. The other viscera were healthy.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF WILLIAM SANDS COX, ESQ.

By Peter Hinckes Bird, one of the Resident Medical Officers.

(*Continued from page* 42.)

Case XX.

CARCINOMA OF THE MAMMA.

Mary Ann Mason, aged 49, admitted into the Queens' Hospital, May 29th, 1846, under the care of Mr. Sands Cox, to have the operation for the removal of the breast performed. She is unmarried, and of spare habit. She states that last November she first perceived a small tumour on the left breast, accompanied with a sharp darting pain; the tumour was at first moveable, but afterwards became fixed, and the nipple gradually became retracted; it was lanced about three months ago, since which time it has rapidly increased in size; it has been much inflamed lately, and poultices have been applied; the discharge from it has never been fetid; has bled much at times. She states that she has got much thinner lately, but has no cough; her parents are both alive and enjoy good health; she is not aware that she ever received a blow on the part; is very anxious to have the breast removed.

Present State.—On examination, the breast presents a large open wound with fungous granulations, and an inflamed irregular margin; it discharges a thin, but not offensive, matter, which does not excoriate the neighbouring parts; the parts surrounding the wound feel hard; the nipple is slightly retracted, and the integument puckered; complains of occasional, not severe, lancinating pains, as if "strings were pulling;" no enlargement of the axillary glands can be discovered; has no cough; sleeps pretty well, occasionally disturbed by the pain; appetite good; bowels open; tongue clean; pulse pretty strong, 86.

June 1st. The breast was removed this morning by Mr. Cox in the following manner:—The patient being placed on a well-cushioned chair, and the pectoral muscle being rendered tense by an assistant keeping the arm back, two semicircular incisions were made, meeting at their extremities, including the whole of the diseased mass, and the suspicious integument, the direction of the wound being made obliquely downwards and inwards; the entire mass was dissected out, and every suspicious atom carefully removed; three vessels required ligatures; the lower part of the pectoralis major muscle, to which part of the diseased mass was attached, was completely exposed to view during the dissection. The patient bore the operation with stoic firmness; the wound was after a little time lightly dressed, and the patient put to bed.

Examination of the Breast.—On being cut into, the diseased mass afforded considerable resistance to the knife, and gave the squeak peculiar to scirrhus; septa were seen diverging from the centre to the surrounding parts; in various parts of the breast were also several cysts, containing a yellowish serous fluid; these cysts occupied the place of the true glandular structure. A small portion of the scirrhous mass under the microscope presented the cells peculiar to it, embedded in their stroma.

June 3rd. Sleeps well at night; complains of slight pain in the wound, which looks healthy.

10th. Doing well; granulations healthy; no lancinating pain in the wound; no swelling of the axillary glands; appetite good; getting stronger.

20th. The wound is granulating over, and presents a healthy appearance; health improved.

July 3rd. Doing well; cicatrization is rapidly proceeding.

23rd. Nearly healed over; complains of no pain in the wound; no swelling of the axillary glands.

28th. Quite healed; health much improved; looks better, and is decidedly fatter; no cough. Discharged cured.

Of the organic affections to which the female breast is liable, cancer is incomparably the most common and the most important; the scirrhous species is by far the most frequent; the encephaloid but rarely occurs; while colloid, especially as constituting the mass of a tumour, is excessively uncommon.

It is said to be of more frequent occurrence in women who have not borne children, whether married or single, than in mothers. Sir Astley Cooper thinks it very probable that the natural change which the breast undergoes in the secretion of milk, has some power in preventing this disease; he knew one individual, however, with this disease, who had been pregnant seventeen times. Its evolution seems connected with the disappearance of the catamenia, for it most frequently appears in women who have had their change of life, its occurrence before the age of 30 being extremely uncommon. This patient was in her 49th year. According to Sir Charles Bell, scirrhus of the breast belongs to that period of life when the uterine functions cease; menstruation becomes irregular, both in respect to time and quantity; long intervals occur,

after which the discharge is profuse, with unusual disturbance of the general system, The great sympathy between the uterus and the mamma is very remarkable; and upon this sympathy the affection of the mamma does, in a great measure, depend. Mr. Carmichael has, however, seen scirrhus of both mammæ in a child, aged 12; and Sir Everard Home relates a case in which it occurred at the age of 15. On the other hand, persons of the most advanced age are not exempt from the chance of its development. Dr. Walshe relates the case of a female under his care who was nearly 70; Sir Astley Cooper has seen the disease in a female, aged 86; and Cruveilhier maintains that such facts are of almost too frequent occurrence to be looked on as exceptional.

According to the opinion of Sir Astley Cooper, scirrhus of the breast occupies from two to three years in growing, and from six months to two years in destroying life; but in this case, the patient only perceived it seven months previous to its extirpation. This case is also remarkable for the absence of pain, which was never much complained of, and was seldom attended with exacerbations; the case is also peculiar on account of the number of cysts which occupied the substance of the breast.

The results of the operation for the extirpation of cancer are very unfavourable. Mr. Mayo's experience* has led him to the conclusion that, "after amputation of a scirrhous breast, *under the most favourable circumstances*, that is to say, when the operation is performed at the earliest period at which the structural character of the disease has declared itself in the gland, no other part being yet invaded by it, and the diseased structure being entirely removed, I believe that *in ninety-nine cases out of a hundred the disease returns* either in the cicatrix, or in the axillary or subclavian glands. The operation, therefore, cannot be performed with any reasonable prospect of saving the patient eventually from the disease." Dr. Macfarlane states that he has "never seen a case, *even of the most favourable description, in which the disease did not return*, although every precaution was adopted to render the operation successful." Dr. Macfarlane refers to 118 cases, and although in the majority the parts were freely and extensively removed, at an early period, and under the most favourable circumstances, in many instances no distinct indication of constitutional deterioration being present, yet in *all* the disease returned both externally and internally, and proved fatal.

What then, are the cases in which amputation of a scirrhous mamma may be deemed proper? Sir Benjamin Brodie gives the following reply:—"When the skin is perfectly sound—when the nipple is not retracted—when there is no diseased gland in the axilla—when there is no sign of internal mischief—when there is no adhesion of the breast to the parts below—and when the patient is not very much advanced in life, I should say, that there is a reasonable chance of an operation effecting a cure. I do not intend to say that in all expected cases there will be a permanent cure, far from it; but there will be in some instances, and the chance of it may be sufficient to warrant you in recommending the patient to submit to the operation. I have the satisfaction of knowing, that several persons on whom I have operated under these circumstances, are now alive and well, but who would certainly have been dead long since, had I not had recourse to it."

I may here remark, that the treatment this patient received three months previous to her admission into the hospital was unwarrantable in the extreme; no man, who understands his profession, would ever think of thrusting his lancet into a scirrhous breast; for this imprudent act caused in this case, by the irritation it produced, the rapid increase in the tumour, and the throwing out of an extensive fungus, which, by repeated bleedings, was enfeebling the patient.

* Outlines of Pathology, p. 573.

Case XXI.

COMPOUND FRACTURE OF BOTH THIGHS AND LEGS.

Samuel Hare, aged 40, labourer on the Gloucester railway, admitted into the Queen's Hospital, on July 29th, 1846, at half-past five o'clock, p.m. It is stated that about an hour previously, a loaded luggage train passed over the lower part of his body; he did not lose much blood at the time.

When admitted he was in a complete state of prostration, with cold skin, weak slow pulse. On examination, there was found compound fractures of both legs and thighs, with a large lacerated wound on the right thigh; very slight oozing of blood from the wound. Stimulants were administered, but he gradually sank, and expired at twenty minutes past six o'clock, p.m.

On *post-mortem* examination the next morning, the following extensive injury was discovered:—A compound comminuted fracture of the right femur, about its middle third, with a large lacerated wound, extending more than six inches from above downwards, and four inches across, the muscles beneath on the inner side of the thigh being extensively lacerated and torn; comminuted compound fracture of the right tibia and fibula, the former bone being much shattered at the junction of its middle, with its upper third; a lacerated wound on the outer side of the right ankle, and one also on the sole of the foot; a compound comminuted fracture of the left femur, with a lacerated wound of about half the size of that on the right; a very extensive compound comminuted fracture of both the bones of the left leg.

No wounds or fracture of any other part of the body was discovered; the marks made by the carriage wheels are very evident on the right thigh.

The severe nature of the accident caused in this patient such a prostration of the system, that re-action did not ensue; had he revived amputation of both thighs above the seat of injury, would have been the only chance left for recovery.

(To be continued.)

NORTH STAFFORDSHIRE INFIRMARY.

CASE OF EXOSTOSIS OF THE TIBIA, AND OPERATION.

By J. Seddom, M.D., F.R.C.S., &c., lately one of the Surgeons to the North Staffordshire Infimary.

Joseph Hubball, agricultural labourer, aged 21, married, of florid complexion and healthy appearance, was admitted into the North Staffordshire Infirmary, January 5th, 1846. About two years and a half ago, his attention was first called to a "lump" in the upper and back part of the right leg, by uneasiness in the part, which was attended with occasional numbness in the ankle; there is no very marked swelling of the part, but the muscles of the calf, on examination, seem to be stretched, and a hard tumour can be felt firmly attached to the upper and posterior part of the tibia. A pulsating blood-vsssel can be traced on the outer edge of the tumour. The patient thinks the swelling may have been caused by leaping. Leeches, blisters, and other measures had been resorted to before his admission. He was directed to take Potassii Iodidi, gr. iv., twice a day, and he had a strong compound iodine solution to apply to the tumour.

This plan was unremittingly pursued till the middle of April, but the tumour had become decidedly larger, and the patient was now suffering considerable pain. A consultation of my colleagues was therefore called, when I submitted for their consideration a proposal to remove the tumour by excision; this was decided upon, and the operation undertaken, May 2nd.

A free incision, commencing at the lower part of the poplitieal space, and within the inner hamstring, was extended about four inches downwards, on the inner edge of the gastrocnemius, and parellel with it. This was continued across the muscle, and carried a little upwards, so that the cut had somewhat of a hooked appearance. By this means, a flap was formed of the muscles of the calf, which was turned upwards; two bleeding vessels were tied at this stage of the operation. The tumour now became apparent, covered only by an expansion of muscular fibres. The house-surgeon, Mr. S. Alford, having drawn aside the vessels and nerve, by means of a hooked copper spatula, the muscular fibres were divided so as to expose the tumour clearly; it had an extensive attachment to the tibia, and overhung its inner edge, so as to fill up the interosseal space at this part. By means of a chisel and mallet applied to its inner edge, it was partially divided; the chisel was then worked into the internal structure of the tumour, with the hand alone, and by raising the handle of the instrument, the bony mass was forced from its attachment; a few projecting points of bone were removed by the bone-nipper. Some lint having been applied to the bottom of the wound, the muscular flap was laid down, and a piece of lint placed over it, and this being retained by a bandage loosely applied, the patient was carried to his bed. Sumat Tinct. Opii, min. xxv. e Mist. Camph., oz. j. statim. Hydrarg. Chlor., gr. iv., hora somni.

The operation was effected with much less difficulty than was anticipated. The tumour was as large as a middle-sized potato, had a nodulated appearance, and a flesh colour, having somewhat the resemblance of large granulations; but this appearance was only superficial; internally it had a cancellated bony structure. The diameter of its base was nearly three inches.

May 3rd. The limb somewhat swelled; the bandage and outer dressings were removed, and lint soaked in warm water applied.

4th. Going on favourably; some fever; bowels have not been moved. Med. Efferv. Ol. Ricini, oz. ss. Appl. Catapl. Lini vulneri.

6th. Some erythema about the ankle. Appl. Catapl. Lini parti affectæ.

12th. Going on well; the muscle bulges from the wound, but has a healthy granulating appearance; general health good. Middle diet. White lead cerate spread on lint applied to the wound, and support given by a bandage.

17th. Improving. Lint wet in sulphate of zinc lotion applied to the wound, and support given with adhesive straps and bandage.

From this time the patient continued to improve. He was discharged cured, June 30th. Soon after his discharge he resumed his employment as a farmer's servant. I have lately heard of him, and learn that he is perfectly well, and follows his employment without inconvenience.

The difficulties of the operation which presented themselves to myself and colleagues before it was undertaken were:—First, the danger of wounding the vessels and nerve, passing from the poplitieal space; secondly, it was thought possible that the tumour might extend so far upwards as to endanger the opening of the capsule of the joint; and lastly, if the excrescence were of a firm texture there might be considerable difficulty in detaching it from the bone. However, as it was considered that amputation of the limb would soon be required if the tumour continued to increase, it was decided to undertake its removal, having first apprized the patient of the difficulties and danger of the case. I had no apprehension that the disease was of a malignant character, as the patient had a healthy aspect, and his general health had always been good.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, FEBRUARY 10, 1847.

We have lately had our attention drawn to an important document from Mr. Chadwick, which, although addressed to a local authority, the Town Clerk of Liverpool, and for a special purpose, yet contains the enunciation of sound principles, of general application in reference to the subject of which it treats.

This document is in the form of a letter—a well-merited testimonial to the unwearied zeal,

research, and talent evinced by Dr. W. H. Duncan, of Liverpool, in his labours for the sanatory improvement of that emporium of our commerce. The members of the Association will well remember the series of admirable papers on the epidemic fever of Liverpool, by Dr. Watson, published in the Journal of last year, and it is unnecessary to recal the details connected with the sanatory condition of the town therein recorded. It will be sufficient for our present purpose to state, that among the evidence given before the Health of Towns' Committee, to which, and to the reports made to the Commission of Inquiry, it is mainly owing that the attention of the Government and the Legislature has been drawn to the subject, the information afforded by Dr. Duncan on the sanatory condition of Liverpool stands prominent. As Mr. Chadwick, in the letter to which we are referring, justly states, Dr. Duncan's report on the means of improving the health of the population of Liverpool is "one of the most valuable pieces of service that have in their own time been rendered to that population." This he subsequently characterises, in conjunction with other similar reports by Dr. Arnott, Dr. Kay, and Dr. Southwood Smith, Dr. Laycock, Mr. Roberton, and Mr. P. Holland, Dr. Lyon Playfair, Mr. Clay, Dr. Shapter, and Mr. Baker, on the sanatory condition of the metropolis, of York, Manchester, Lancaster, Preston, Exeter, and Leeds, as "reports which advance the new and most important science of prevention, and indicate the principles of a course of measures, which, if they be completely carried out under scientific direction, it may be confidently expected will do more for the improvement of the moral as well as physical condition of the population than any set of measures that have hitherto been presented for the public attention."

The Corporation of Liverpool, roused at length to the importance of attention to sanatory measures, are making the necessary arrangements for carrying into effect those improvements in drainage, ventilation, &c., which have so long and so loudly been called for. Some details as to the pressing necessity for this are afforded by Mr. Chadwick in his letter:—

"It appears," says Mr. Chadwick, "that during one year the excess in number of deaths in Liverpool was no less than 10,000 above the general average mortality of the country. In the year when Dr. Playfair examined Liverpool, with other towns in Lancashire, the excess in the number of deaths in Liverpool above the rate of mortality in Ulverstone, in the same county, was 3611. The loss of life by all who died that year, as compared with Ulverstone, was, on the average, twenty-one years:—the loss of life of the adults who died in Liverpool, as compared with Ulverstone, was on the average, twelve years and six months to each individual. Supposing the lost labour of these adults to be worth only ten shillings per week, the lost productive labour of that year was, demonstrably, a loss of nine hundred thousand pounds. The loss from the excess of sickness which accompanies the excessive mortality,—supposing twenty cases of sickness to one death, and the expense of cure or alleviation only one pound per case, must have been one hundred thousand pounds:—the loss of expense from the excess of funerals alone, at only five pounds per funeral, must have been eighteen thousand pounds during that one year.

"Now, there were at the time of the census 165,094 adults in Liverpool. The impending loss of life to each of these adults is twelve years and a half—that is to say, of death twelve years and a half—before others whose sanatory condition is better, will have to submit to the general doom. Taking this premature loss of life in the pecuniary view merely,—reckoning the value of each adult's productive labour at no more than ten shillings a week,—the impending loss is at least £325 per adult individual."

Such is the loss experienced by the population of Liverpool in life, health, and productiveness. Let us now see what are the arrangements which are to be made to meet it. Among the foremost of these is the establishment of an efficient system of inspection and the appointment of a qualified inspector. The actual extent and nature of the evil must be detected and laid bare before the proper remedies can be applied; and these again require to be indicated, the best mode of their application to be pointed out, so as to accomplish the end proposed, and their working, also, to be superintended by competent persons.

"The subject matters of the attention of the officer of health," we again quote from Mr. Chadwick, "are those causes which affect the condition of the population in the wholesale, causes which frequently cannot be met by separate and isolated arrangements in single cases. For individual cases, alleviation only is in general available; and the business of alleviation or cure, now engages the chief, if not the sole, occupation in the borough of Liverpool of twenty-seven physicians, 325 surgeons and apothecaries, and 365 chemists and druggists."

To meet this requirement the wealthy Corporation of Liverpool proposes the appointment of a medical inspector, with a salary of £300

per annum! with liberty to engage in private practice!! In reference to the labours of Dr. Duncan, Mr. Chadwick observes:—

"At the very outset, I would say that a *pension* of £300 per annum would be but a sorry recompence for what he has already done for the population of Liverpool, by the preparation of the two reports on their sanatory condition."

He elsewhere shews, in reference to the proposed amount of salary, that—"For the more important business of *prevention*—for investigating and indicating the removable or preventible causes of sickness and mortality, which ravage a population of from 280,000, or more, of persons, it appears that the Corporation propose to appoint one officer only, and to pay very little more than £1 per thousand of the persons whose general health it will be his business to protect, by indicating the general arrangements requisite for that purpose!"—and that the proposed expenditure to ascertain and point out the means of averting the impending loss of £325 per adult individual before alluded to, is "at the rate of half a farthing per annum for each adult."

"My estimate," observes Mr. Chadwick, "of the service requisite for the initiation of measures of prevention in Liverpool was of three or four officers of health at the least, giving their whole time to the service, at an expense of £2,200 per annum, which, if efficiently directed, would be a very economical expenditure, as powerfully tending to reduce the annual charge of £18,000 for the excess of funerals alone. But the intended compensation for the inadequate pecuniary provision, for the services of one officer, that he may take private practice, is entirely destructive of all efficiency, even if a full number of officers were appointed, and the remuneration assigned were adequate."

And again, in reference to the subject of combining private practice with the discharge of public duties:—

"Regular private practice not only acts constantly as an inducement to the neglect of regular public duties, but often as a severe penalty for the proper performance of them. In tracing the causes of epidemics, the officer of health must at least occasionally find it in the mismanaged or neglected state of properties owned by his patients, or by persons holding local public office, persons of powerful influence, who sooner or later may exert it to his prejudice."

It will not fail to be observed, that the foregoing remarks, though applied to the individual case before us, are capable of being extended to other localities, and to other official medical duties performed throughout the country for a very inadequate amount of remuneration, for the smallness of which the opportunities afforded for private practice have been held out as an inducement and a compensation. We rejoice to see Mr. Chadwick taking so just a view of these transactions, and we cannot but think that the intercourse which that gentleman has enjoyed in the course of certain of his official duties with such men as Dr. Duncan, by rendering him better acquainted with the talents, energy, and devotion required for the efficient discharge of medical duties, has tended to remove some early prejudices from his mind.

We shall conclude these observations with one more extract from this admirable letter:—

"It is possible, and probable, that Dr. Duncan might be quite willing to perform the services in question gratis, and even be at expense (as he must already have been,—and I have reason to know he has been) in performing them;—but that does not alter the question or the pernicious character of the example.

"The principle set forth by Mr. Burke in his speech on economical reform, as applicable to public offices of the general government, are equally applicable to such local offices as the one in question. 'I will,' he says, 'even go so far as to affirm, that if men were willing to serve in such situations without salary, they ought not to be permitted to do it. Ordinary service must be secured by the ordinary motives to integrity. I do not hesitate to say that that state which lays its foundation in the rare and heroic virtues will be sure to have its superstructure in the basest profligacy and corruption. An honourable and fair profit is the best security against avarice and rapacity, as in all things else a lawful and regulated enjoyment is the best security against debauchery and excess.'"

Review.

Lectures on the Comparative Anatomy and Physiology of the Vertebrate Animals. Delivered at the Royal College of Surgeons, of England, in 1844 *and* 1846. By RICHARD OWEN, F.R.S. Part I. Fishes. London. 8vo. pp. 308,

At no period, perhaps, has natural history, ancient or modern, been so extensively and successfully cultivated, as at the present day. The Fauna of bygone ages has been illustrated, and the science of zoology, as it now exists, elucidated by the labours of Hunter, Cuvier, Buckland, Owen, Agassiz, and others. The impulse which has been given to science by the British Association, and the interesting expeditions which have been undertaken for scientific, purposes.

have undoubtedly tended to direct the public taste into this channel; but from higher considerations, the importance of a knowledge of the anatomy of the inferior animals, and a familiarity with their habits, has been of late more fully recognised; and there is reason to believe that ere long, natural history will be received as a part of general, as comparative anatomy is now of medical, education. To our illustrious countryman, John Hunter, to the immortal Cuvier, and to Owen, upon whom the mantle of Cuvier has been gracefully described as having descended, are we indebted for the most valuable discoveries in this department of science.

Independently of his other important works, the "Lectures on Comparative Anatomy," by Professor Owen, have been generally recognised as conveying the most valuable and profound information on that subject which has yet been communicated; and we hailed the appearance of the second volume with unmitigated pleasure, which has been increased rather than diminished by its perusal. After a careful consideration of its contents, we pronounce it to be a work which must add greatly to the already high reputation of its author.

It will be recollected that in 1843, Mr. Owen published a volume of lectures "On the Anatomy of the Invertebrata." Various causes delayed the appearance of the present volume beyond the period originally intended for its publication; but we have no reason to regret that circumstance, as the Professor informs us, that "The desire to verify some of the propositions there enunciated, by repeating the observations on which they were founded, has led to many new dissections and examinations of numerous specimens; and that the utility of the present volume has been farther regarded, by ingrafting into the text some remarkable discoveries with which the science of comparative anatomy has been enriched, since 1844; and by adding details, which the time allotted to the Hunterian course compelled me to omit in the theatre."

Our space will not admit of our entering into the merits of the work *seriatim*; we must confine ourselves therefore to a cursory survey of its contents. The Introductory Lecture deserves a careful perusal; and many of its passsges are full of beauty. Take for instance the following:—

"And first permit me to dwell a little on the inestimable privilege which we enjoy in entering on our professional studies, by the portal of anatomy. How vast and diversified a field of knowledge opens out before us as we gaze from that portal? Consider what it is that forms the subject of our essential introductory study; nothing less than the organic mechanism of the last and hightest created product which has been introduced into this planet. Contrast this, which both sage and poet have called the 'noblest study of mankind,' with the dry and unattractive preliminary exercises of the lawyer or the divine. Every new term which the anatomical student has to commit to memory is associated with a recognisable object,—with some part which may be vibrating, contracting, or pulsating in his own frame.

Again, "We know that it has pleased God to grant us faculties, by the right use of which we may obtain a true knowledge of His works; and it seems part of His providence to permit certain parcels of knowledge to be thus introduced from time to time, to the dissipation of the erroneous notions which previously prevailed. By the exercise of these faculties, the true shape of our spheroid was determined, and after some opposition, accepted; next its true relations to the sun, as repects its motion. It has been reserved for the present generation to acquire more just ideas of the age of the world; and anatomy has been, and must be, the chief and most essential means of establishing this important element in the earth's history. But anatomy aids not only the geologist, but the geographer. By comparing the local distribution of restored extinct species from coeval geological strata over all the earth, with the geographical distribution of existing animals, we obtain an insight into the past conditions of continents and islands; we determine that our own island, for example, once formed part of the continent, and obtain data for tracing out much greater mutations and alternations of land and sea."

The following five lectures are devoted to a consideration of osteological homologies, and the osteology of fishes. "The great aim," says Mr. Owen, "of the philosophical osteologist, is to determine by natural characters, the natural groups of bones, of which a vertebrate skeleton typically consists; and next, the relations of individual simple bones to each other, in these primary groups, and to define the general, serial, and special homologies of each bone throughout the vertebrate series."

The opinions brought forward by the author on this subject, bear evidence of acute observation, profound thought, and sound judgment; and will, we think, be found to stand the test of time. Interspersed with the necessary detail—which is as interesting as a description of bones can be—are observations indicative of much sagacity, and a just appreciation of the adaptation of means to ends.

"The predaceous sharks are the most active and vigorous of fishes; like the birds of prey, they soar, as it were, in the upper regions of their atmosphere, and, without any aid from a modified respiratory apparatus, devoid of an air-bladder, they habitually maintain themselves near the surface of the sea, by the actions of their large and muscular fins. The gristly skeleton is in prospective harmony with this mode and sphere of life; and we shall subsequently find as well marked modifications of the digestive and other systems of the shark, by which the body is rendered as light, and the space which encroaches on the muscular system as small, as might be compatible with those actions; besides, lightness, toughness, and elasticity are the qualities of the skeleton most essential to the shark. To yield to the contraction of the lateral inflectors, and aid in the recoil, are the functions which

the spine is mainly required to fulfil, in the act of locomotion, and to which its alternating elastic balls of fluid, and semi-ossified bi-concave vertebræ, so admirably adapt it. To have had their entire skeleton consolidated and loaded with earth's matter, would have been an encumbrance altogether at variance with the offices which the sharks are appointed to fulfil in the economy of the great deep."

Contrasted with the sharks are the sturgeons. "The sturgeons were designed to be the scavengers of the great rivers: they swim low, grovel along the bottom, feeding in shoals on the decomposing animal and vegetable substances which are hurried down with the debris of the continents drained by those rapid currents. Thus they are ever busied, re-converting the substances, which otherwise would tend to corrupt the ocean, into living organised matter. These fishes are therefore duly weighted by a ballast of dense dermal osseous plates, not scattered at random over their surface, but regularly arranged, as the seaman knows how ballast should be, in orderly series along the middle and at the sides of the body. The protection against the waterlogged timber and stones hurried along their feeding grounds, which the sturgeons derive from their scale armour, renders needless the ossification of the cartilaginous case of the brain, or other parts of the endo-skeleton: and the weight of the armour requires that endo-skeleton to be kept as light as may be compatible with its elastic property and other functions. The sturgeons are further adjusted to their place in the liquid element, and endowed with the power of changing their level, and rising with their defensive load to the surface, by a large expansive air-bladder."

The myology of fishes is described in the seventh lecture; their neurology and organs of special sense in the eighth. The ninth is devoted to their digestive organs; whilst the two last chapters treat at length of their pneumonic and renal systems, their generative system and development.

We must here close our hasty sketch, which we do with reluctance, feeling how little such a notice as the present can convey an adequate idea of the merits of the work; but we have at least the satisfaction of knowing, that it may have the effect of attracting attention to the volume itself, the perusal of which will repay any amount of time or labour bestowed upon it.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

November 7th, 1846.

JOSIAH CLARKSON, Esq., in the Chair.

ABSCESS OF THE SPLEEN.

Mr. W. C. Freer exhibited a specimen of abscess of the spleen, taken from a patient who had died of fever.

Charles White, aged 30, single, a servant. At the commencement of August he began to experience deep-seated pain in the epigastric region, and deranged digestion and occasional vomiting. In September fever came on, and he became an in-patient of the hospital. On admission, his symptoms were those of the epidemic idiopathic fever, requiring stimulants. His reason failed for some time, and on recovery he directed attention to an abscess as large as a child's head, on the left side of the lumbar spine, presenting precisely the appearance of the common lumbar abscess connected with diseased bone. He died October 15th.

Autopsy.—An abscess of the spleen at the back of the peritoneum which was unruptured; stomach, liver, and other viscera healthy.

ANEURISM OF THE AORTA: STEATOMATOUS TUMOUR.

Mr. W. C. Freer next presented an aneurism of the arch of the aorta, taken from a woman aged 50; also the uterus from the same patient, which had two small steatomatous tumours between it and the rectum, the os tincæ being a mere point.

Isabella Haines, aged 50, has considered herself asthmatical for some years, and has frequently had attacks of spasmodic dyspnœa. She became an in-patient of the hospital, and died shortly after admission, no opportunity being afforded for an investigation of the case.

Autopsy.—An aneurism of the arch of the aorta, the size of an orange, the cavity being partially formed by distension of all the coats of the artery, and the remainder by a true aneurismal pouch, the aperture of communication being circular, and an inch and a half in diameter. The right lung was much smaller than the left, apparently from pressure upon the right bronchus having allowed but a small quantity of air to enter the lung. The uterus had two small steatomatous tumours between it and the rectum, the os tincæ being a mere point.

ADHESION OF THE PLACENTA: INFAMMATION OF THE UTERUS

Mr. W. C. Freer exhibited a uterus taken from a patient aged 24, who had miscarried, in which a considerable portion of the placenta remained attached over the right Fallopian tube; he gave the following history of the case.

Jane Williams, aged 34, at the commencement of October, suffered from some general derangement of health, and miscarried with her fifth child the middle of October. She lost a large quantity of blood and shortly afterwards symptoms of typhoid puerperal fever presented themselves. She became an in-patient of the hospital on the 4th of November, and had the following symptoms:—Uterine tenderness, acute pain in the right thigh, jaundice, pulse 130 to 150, and extreme prostration. She died on the 6th instant.

Autopsy.—A considerable portion of placenta remained attached over the right Fallopian tube; the mucous membrane of the uterus was disorganized, and the uterine sinuses contained pus. The kidneys were slightly diseased. The other organs of the body were healthy.

MENINGEAL APOPLEXY.

Mr. James Russell, jun., exhibited a portion of a

brain taken from a patient who had died suddenly from effusion of blood over the entire surface of the brain. He gave the following particulars:—

Mrs. T.———, aged 35, for the last three years has suffered from pain in her forehead at frequent short intervals, seldom exceeding a fortnight in duration. Has had no other complaint. On the evening of October 13th she was visiting her sister, and was sitting with her head leaning on her hand, when having just completed a sentence, her head dropped, her hands fell lifeless, and in ten minutes she was dead. Mr. Hinds saw her in about six or seven minutes, he informs me that she made about three stertorous inspirations after his arrival; her face was perfectly pale; the heart was beating.

Sectio-cadaveris forty-five hours after death. Body well nourished; stature rather tall; rigor mortis very firm; face quite pale; decomposition had not commenced; a considerable quantity of blood had issued from the wound at the bend of the arm. On removing the calvarium, fluid-blood flowed apparently from the outer surface of the dura mater, probably from the longitudinal sinus. The pia mater was enormously congested over the whole surface of the brain, excepting at the vertex, in the space of the palm of a small hand; the vessels of the pia mater were all surrounded by ecchymosis in the meshes of its cellular tissue, mottling the surface of the brain with bright red; the same appearance extended down the great fissure on either side at the corpus callosum. On the anterior edge of each hemisphere was a large thick patch of effused blood; and in a subsequent stage of the dissection, on slicing the brain, the cut surface of the convolutions exhibited a bright red line, produced by the processes of the pia mater. Towards the base the effusion became more abundant and more uniform. At the base the olfactory nerves were matted together with blood, as were the optics. The pons was concealed by a dense coagulum, which also completely enveloped the medulla oblongata for the thickness of half an inch. A coagulum also lay on the under surface of the cerebellum; and a very thin lamina of blood covered all the cerebellum. From the examination we could make from the base of the skull, the upper portion of the cord was also enveloped in blood. The great vessels at the base were healthy; the cerebral substance very firm, except the fornix, which was very soft; corpora striata and thalami healthy; the ventricles contained a considerable quantity of serum, apparently tinged with blood; choroid plexures and velum interpositum very pale; the cerebral substance generally very exsanguine, as was especially seen in the grey matter; the integuments of the head were not loaded with blood. Heart quite healthy, small, and rather contracted; right side contained fluid blood, but not in nearly sufficient quantity to fill the cavities; the left side contained a very small quantity of dark fluid-blood; (the state of the cavities was ascertained before any wound of the vessels;) about half a pint of serum in each pleural cavity; lungs very dark, and loaded with bloody serum, crepitated imperfectly; the middle lobe of the right lung, however, presented its healthy appearance; some emphysema at the apex of the right lung. Liver healthy, fluid-blood flowed freely from its divided surface; kidneys very firm, apparently much congested; intestines pale. Vena cava contained liquid blood; aorta nearly empty.

December 5th, 1846.

James Russell, Esq., in the Chair.

HYDATIDS FROM THE UTERUS.

Mr. Brindley presented a specimen of uterine hydatids, discharged by a patient, aged 32, who supposed herself to be in the 5th month of pregnancy. She had aborted six or seven times about the third month, and had been twice delivered of dead children at the full period.

MICROSCOPICAL SOCIETY OF LONDON.

EXAMINATION OF DELICATE ORGANIC STRUCTURES.

A paper was read at a late meeting of this Society by John Anthony, Esq., "On a Method of Rendering the Appearances in Delicate Structures visible by Means of Oblique Transmitted Light." This method depends upon the placing the object in such a position that the fine lines or other delicate markings are exactly at right angles to the illuminating rays, when these lines, &c., will be at their maximum of distinctness, and thus tissues may be rendered distinctly visible whose existence when viewed in the ordinary manner might be considered as exceedingly doubtful. The object employed to illustrate this position was the navicula of the Humber, one of the most delicate of test objects, which, under ordinary circumstances, appears perfectly transparent; but when viewed in this way, not only exhibits a double set of lines, but also transverse lines, giving the whole the appearance of being covered with a delicate net-work.

Four drawings of this object were exhibited, showing it in as many different positions, making a complete revolution of the field in which the markings just mentioned were distinctly visible. In order to bring out these appearances, it is necessary that the light should be very oblique, and must be passed laterally through the "bull's eye," in such a manner that the object (the navicula,) may appear of an intensely blue colour, nearly opaque. The stage is then to be gradually turned round until the shell is in the position to be best seen as described.—*Annals and Magazine of Natural History*, January, 1847.

[This process is obviously equally applicable to the examination of delicate vegetable and animal structures in general. Mr. Legg, in a paper "On the Application of Polarized Light in Microscopic Observations," read at a subsequent meeting of the Society, described a series of polarizing apparatus, capable of being adapted to the microscope, and calculated to effect a similar object, the analysis of the structure of delicate organic textures being thus effected by the action of polarized light.

NATIONAL INSTITUTE OF MEDICINE, SURGERY, AND MIDWIFERY.

We have been requested by the Committee of the National Institute of Medicine, Surgery, and Midwifery, to insert the subjoined address.

TO THE GENERAL PRACTITIONERS OF MEDICINE, SURGERY, AND MIDWIFERY.

GENTLEMEN,—In the expectation that an inquiry into the state of the Laws affecting the Medical Profession in this country will very speedily engage the attention of the Legislature, the Council of the National Institute of General Practitioners in Medicine, Surgery, and Midwifery, have presented a Memorial to the Right Honourable the Secretary of State for the Home Department, describing the anomalous position of the very important section of the Profession which they represent, and calling the attention of the Government of this Country to some of the great and acknowledged evils and disadvantages that press peculiarly upon that section as a class. The Memorial also prayed for the assistance of the Government—on Public as well as on Professional considerations—to obtain the amelioration of those evils and disadvantages with as little delay as possible.

To the document in question, the Council of the National Institute invite the earnest attention and serious consideration of all classes of Medical Practitioners. The Medical Profession in England is at this moment surrounded by the greatest difficulties from inadequate Laws and ill-adapted Institutions; whilst many causes have combined for a long series of years to arrest and to render abortive every attempt to amend and re-construct them. This is surely a matter of sufficiently serious importance to deserve a small share of time and attention from each of its members; and were a body of intelligent and honourable-minded men to enter upon the consideration of the subject in a liberal and patriotic spirit, they would find little difficulty in agreeing upon such a general measure of reform as would be acceptable to a large majority of the Profession.

In the absence, however, of such general accordance, and with a view of clearing away some of the difficulties in the way of a satisfactory solution of this complicated question, the Council of the National Institute beg to recall the attention of the General Practitioners in particular, to the circumstances which immediately followed SIR JAMES GRAHAM'S first attempt at Medical Legislation:—When the details of the proposed Bill were carefully examined, the General Practitioners were for the first time made sensible of their own extraordinary position; that although they numbered nine-tenths of the entire Profession, they were unknown as a *collective body;* that they had no *corporate rights*—no *council* nor *executive* to express their wishes or opinions—nor had they any *Common Hall* wherein they could assemble for the purpose of consultation.

The disabilities above referred to were so manifestly injurious to them, that at the first Public Meeting, held at the Hanover Square Rooms, on the 7th of December, 1844, at which nearly one thousand General Practitioners were present, the following resolution was the first proposed and unanimously adopted:—

"That this Meeting is decidedly of opinion, that prior to the passing of any Bill for the regulation of the practice of Medicine and Surgery, it is of the utmost importance to the interests of the Public, that the General Practitioners of Medicine, Surgery, and Midwifery, should be legally recognized and placed in an independent position; and that the Executive Government be respectfully and earnestly requested to suspend the further consideration of the Bill laid before Parliament at the close of the last Session, until this object has been attained."

The Council refer with confidence to the events of the last two years, for a full verification of the principle contained in the foregoing Resolution. By neglecting to perform, in the first instance, an act of common justice to the great bulk of the Profession, a powerful Minister, with all the Government support at hand, after introducing four successive Bills before Parliament, was compelled reluctantly to withdraw the whole of his contemplated measures—thereby acknowledging his inability to complete what he believed to be a most important and necessary measure of Legislation.

That such will be the fate of every attempt at Medical Legislation,—whether it be a simple matter of Registration, or a measure embracing the whole question, is the opinion of the Council of the National Institute, unless an ostensible recognized head and home be found for the General Practitioners—as an indispensable and necessary preliminary to any more extensive or comprehensive measure of Medical Reform. The Council consider it of the utmost importance that the class of Practitioners to which they themselves belong, should, without a moment's unnecessary delay, meet, and strenuously support, the Council in the prosecution of their just claims to a legal recognition; and they have every confidence that their Professional brethren will see the necessity that exists for immediate action, before the attention of the Government, the Legislature, or the Profession is pre-occupied by the consideration of the claims made by the Medical Corporations, or of the proposed Medical Registration Bill. The latter proceeding is most unquestionably ill-timed, whatever may be its intrinsic merits; for, until the General Practitioners are duly recognized as a collective body, with what security can they consent to a Legal Registration, that may place them irretrievably in an inferior and subordinate rank. With these observations the Council conclude by again directing attention to the Memorial presented to the Government, and they call upon their professional brethren, in the true spirit of patriotism, to merge all minor differences of opinion on this important subject, and with the calmness and deliberation befitting a body of scientific and intelligent men, to unite and determine upon some uniform plan of co-operation that may secure an early and satisfactory settlement of the affairs of the Medical Profession.

Signed on behalf of the Council,
ROBERT RAINEY PENNINGTON,
President.

Offices, *pro, tem.*,

General Retrospect.

ANATOMY AND PHYSIOLOGY.

RUDIMENT OF A UTERUS IN MAN, AND IN MALES OF THE MAMMALIA.

M. Ernest Weber, professor of anatomy at Leipsic, has reported the extraordinary anatomical discovery of the rudiments of a uterus in males of the mammalia. He states:—

1. That in the males of all animals as yet examined by him, including the castor, the hare, the horse, boar, dog and cat, there is a hollow uneven organ placed in the median line, between the extremity of the urinary bladder and the rectum; this he considers to be a rudimentary uterus, and it is called by him the *uterus masculinus*.

2. In man this organ exists in the form of a small elongated bladder, springing from the posterior part of the prostate, and contributing to form the verumontanum.

3. In fœtal rabbits, both males and females, the sex cannot be determined with exactness by the examination of the external genital organs; the internal organs are so similar, that great attention is required to distinguish the male from the female. In both there is a *sinus uro-genitalis*, and a part which might pass for the base of the vagina and the body of the uterus. Into this organ there open in the female the cornua of the uterus; in the male the vasa deferentia, which closely resemble the cornua, with the exception that the latter open into the superior portion, the former into the inferior portion, of the organ. An organ corresponding to a rudimentary vagina, a body and cornua of the uterus, is also seen in the adult male rabbit; it is a non-muscular sac, which contains the semen, and is so irritable that it contracts in the recently dead animal when mechanically excited.

4. In the male beaver, and in the boar, the rudimentary uterus is as in the female, bicornal, situate in the same locality, and covered by a fold of peritoneum.

5. In the dog the orifice of the rudimentary organ appears to be obliterated; as also in the cat. In the horse, and in man, this orifice is also sometimes obliterated, but this is exceptional; in general the *uterus masculinus* of the stallion opens into the urethra, at the verumontanum, by a single orifice.

6. According to the observations of Rathké on the goat and boar, the uterus of the male embryo is at one period so similar to the female uterus as to be scarcely distinguishable from it.—*Archiv. d'Anatomie*, Dec., 1846.

[Sir Everard Home, twenty years ago, pointed out the third lobe of the prostate gland. Is not this the origin of Weber's rudimentary uterus? The organ has been described by Ackermann under the title *uterus cystoides*; and by Guthrie under that of *sinus pocularis*.]

ABSORPTION OF OXYGEN BY THE BLOOD.

The study of the phenomena of respiration was never carried out with an approach to perfection until the chemical knowledge, indispensible to such inquiries, had attained a certain degree of precision. Lavoisier was the first to enumerate the leading proposition:—*Respiration is combustion.* This fundamental proposition being established, it still remained a question, in what part of the system the blood undergoes the changes necessary for the preservation of the economy.

Many theories have at different times been advanced to fill up this hiatus in physiological inquiry. According to Lavoisier, the formation of carbonic acid and water, and the production of azote takes place in the lungs. This theory, against which so many objections have been urged, was nevertheless for a length of time the received opinion, until it was generally abandoned after the publication of the works of Magnus. It was affirmed by that physiologist, that the oxygen of the atmosphere is simply dissolved in the blood of the lungs, and that it is transmitted in this state to the arteries, and that the changes by which carbonic acid is generated take place in the capillaries, the acid so formed, together with the hydrogen, which contributes to the formation of water, being also dissolved in the blood. The blood thus charged is carried to the lungs, and there coming into contact with the air, the carbonic acid is changed for a fresh supply of oxygen, and the same series of phenomena is again reproduced.

The conclusions of Magnus were not, however, destined to remain long without an opponent, for we find that they are combated by Gay Lussac, (*Annales de Chemie*, t. xi.)

There are two leading opinions in the present day concerning the manner in which the oxygen of the atmosphere combines with the constituents of the blood in respiration. According to one of these, the oxygen is dissolved in the blood, and arrives in an uncombined state in the capillaries, and there only unites with some of the elements of the nutritive fluid. Others, without denying the primary solution of the oxygen, suppose that a portion of it enters at once into chemical combination with the blood. They consequently admit that the phenomenon of oxidation takes place in the lungs, while the former limit the production of this phenomenon to the capillaries.

Magnus, in answer to the objections of Gay Lussac, has instituted some new researches into the quantity of oxygen, nitrogen, and carbonic acid held in solution by the blood, which tend still farther to confirm his original opinion. Mulder considers that these experiments do not allow of the deductions which Magnus has drawn from them; as the question is not whether the blood has or has not the power to hold oxygen in solution, but whether this oxygen does not form combinations with the elements of blood, partly in the lungs and partly in the capillaries. In order to examine the question properly, it is necessary according to Mulder, to perform experiments so as to observe, not how much oxygen can be disengaged from blood saturated with air, by the employment of carbonic acid, but how much oxygen is absorbed by venous blood, which does not contain air; in the second place it should be noted how much oxygen can be disengaged in the latter case by the means of carbonic acid. Let us suppose, for example, that venous blood deprived of

air, can absorb $\frac{16}{100}$ volumes of oxygen, and that we can disengage by carbonic acid $\frac{12}{100}$; we are then justified in supposing that this $\frac{12}{100}$ existed in the blood in an uncombined state, and that the remaining $\frac{4}{100}$ had formed chemical unions. Magnus does not allude to such results.

According to Magnus the blood does not contain any substance capable of entering into immediate union with oxygen, but Mulder believes that a fluid of so complex a composition cannot but offer the means of effecting such combinations. He considers, on the contrary, that the action of oxygen on the protein commences at once.

Another question with which Mulder occupies himself, being satisfied that the combination of the oxygen is distributed through the lungs, heart, and capillaries, is the proportion in which the gas combines in each locality. On this point, however, he is not able to offer any definite opinion, but contents himself with further objections to some of the tenets of Magnus.

In considering the different colour of venous and arterial blood, the latter physiologist speaks of the power of the oxide of azote to colour the sulphate of the protoxide of iron by simple solution. It is now, however, says Mulder, ascertained that this colouration is due to a veritable chemical union. In confirmation of this he cites the observations of Peligot. Mulder again denies that arterial is converted into venous blood, by simple solution of carbonic acid, or other acids or alkalies; the change is in his opinion, caused by the production of new transparent substances, which absorb a larger quantity of luminous rays.

Finally Magnus denies the chemical combination of oxygen in arterial blood, because the blood in the lungs is not of a higher temperature than that of the rest of the body. To this, Mulder objects that any augmentation of temperature which might take place is compensated for by the exhalation of water, and by the lower temperature of the venous blood as it arrives at the lungs; and besides, Davy and others have ascertained that the blood in the left ventricle is warmer than elsewhere.

In conclusion, Mulder admits that the solution of a notable proportion of oxygen in the blood is an ascertained fact; but he refuses to acknowledge that with the presence of so large a quantity of oxidizable matters in the blood, the oxidation is deferred until the blood arrives at the capillaries.—*Archiv. d' Anatomie. et Physiologie.* Nov. 1846.

PATHOLOGY & PRACTICAL MEDICINE.

ON VARIOLA, VARIOLOID, VARICELLA, AND VACCINE.

Dr. Koesch, the author of an essay published under the above title, concludes:—

1. That cow-pock is nothing more than small-pox, transmitted to the cow by contact.

2. That persons who have been effectually vaccinated, may in some rare instances contract dangerous small-pox.

3. That small-pox after vaccination, is in the great majority of cases of trifling severity.

4. That the rarity and mildness of small-pox is in proportion to the recency of the vaccination.

5. That small-pox seldom appears after the age of thirty, but is not always less severe when it does so.

6. That the majority of the vaccinated are entirely exempt from small-pox, even though exposed to contagion.

7. The identity of variola and varioloid is demonstrated by their phenomena, development, and by the results of contagion or inoculation.

8. That varicella is in no-wise connected with variola, but is a perfectly distinct disease.

9. That vaccination is the only mode of exterminating small-pox.—*Medicinische Corresp. Blatt.*

PHYSICAL SIGNS OF INCIPIENT PHTHISIS.

M. Dubini has communicated the results of his researches into this difficult subject in semeiology His ideas are for the most part in accordance with those of Fournet, Jackson, Louis, and others, to which he gives valuable confirmation.

In order to study the true signification of modifications of the expiratory murmur, as a diagnostic sign in incipient tuberculization, M. Dubini first endeavours to form an exact appreciation of this murmur in a state of health. As regards its duration and intensity, he adopts the scale of Fournet, which makes it as two, the respiration being as ten, in preference to the evaluation of Barth and Roger. He also lays great stress on the observations of Louis, who found the expiratory murmur prolonged under the right clavicle, but never under the left, in seventeen females exempt from pulmonary disease.

Prolonged expiration is not exclusively confined to the first stage of phthisis; it is met with in chlorosis, in pulmonary œdema, in severe heart diseases, in pleuritic effusions, in bronchitis, and in emphysema; but in emphysema, the expiration is whistling; in bronchitis, which is seldom partial, the whistling expiratory murmur is generally diffused over the chest; and so in other diseases in which the prolonged expiration is present, it exhibits certain peculiarities which distinguish it from the prolonged expiration due to tubercular deposit.

M. Dubini does not regard the above sign as constant in all varieties of tubercular deposit; it is absent when the matter is agglomerated in voluminous masses, (crude turbercle,) between which the pulmonary tissue remains crepitant. The variety in which it is commonly noticed is that which consists in a general infiltration of the pulmonary tissues with miliary granulations. It appears then that prolonged expiration may exist without tubercles, and tubercles without prolonged expiration; but there can be little fear of error when the expiratory bruit is persistent and rough, and more especially if it is unequal, interrupted, and limited to one or other subclavicular region. The diagnosis is rendered next to infallible, if, with this sign, there are accompanying general symptoms proper to the disease. —*Gazette Médicale.* No. 51, 1846.

ON THE USE AND ABUSE OF MERCURIAL PREPARATIONS.

Dr. Sichel gives the following cautions as necessary in the exhibition of mercurial preparations:—

1. The *diet* must be in no-wise stimulant, and as little nourishing as possible. If this is not attended to the plasticity of the blood becomes augmented.

2. All notable change of atmospherical *temperature* should be avoided. Unless this rule be observed, numerous disappointments will occur, and premature salivation is especially likely to be induced.

3. It is a general law that the *special physiological action, or the toxical effect of a medicinal substance, only manifests itself after its action upon the pathological condition* has become exhausted.

The operation of this law is well seen in the employment of narcotics in those affections of the nervous system which afford distinct indications for their use, as neuralgia and tetanus. This last, we know, demands large doses of opium, but the point of saturation must be carefully watched so that the drug may be laid aside when the precursors of narcotism begin to replace the tetanic symptoms; unless we wish to see, as I have often seen in the hospitals, the patient cured of the tetanus to die by opium. The physiological action of mercury is exerted upon the salivary glands, and with the earliest precursory symptoms of salivation, the blood has already lost some of its morbidly plastic character. It is indeed remarkable to what an extent acute inflammation becomes relieved, upon the appearance of the precursors of salivation, and how long these are in making their appearance in intense and essentially exudative inflammations, as iritis, peritonitis, and especially puerperal peritonitis. In this last we are sometimes surprised at finding the abdomen, which the evening before would not endure the weight of the clothes, supporting next day firm pressure of the hand, the precursory symptoms of salivation having manifested themselves in the interval. These are indeed the signs of the system having become sufficiently saturated with the mineral, which must be left off as soon as they appear, our object not being, save in very rare and obstinate cases, to excite actual salivation. Instead of then pushing on the mercury, if the disease does not yield, we must, in the case of inflammation, have recourse to other antiphlogistics; and in the case of syphilis, to iodine, sudorifics, &c., carefully limiting the regimen, and avoiding exposure to cold. When, however, the precursory symptoms are dissipated, and the disease has not yet yielded, we may turn again and again to the mercurial treatment. In syphilis this is almost always necessary.

It is from the non-observance of the above rules, that so much mischief has been caused by this remedy, and so much prejudice has been raised against it. The excitement of profuse salivation is especially mischievous. The anti-plastic action of the drug may, after long use, so diminish the coagulability of the blood, as to produce a *mercurial scorbutus*, very difficult to cure. *Marasmus* may likewise be produced, especially in children and aged persons, if mercury be employed sufficiently long to induce ptyalism or diarrhœa, or the two conjointly. Calomel, particularly, must be given to such subjects with great care. It is not sufficient to withhold it when salivation or purging already exist; but at every visit the condition of the salivary organs and digestive tube must be carefully enquired into. From neglect of this precaution, infants often suffer severely from the prolonged use of calomel.—*Medico-Chirurgical Review*, Jan., 1847, from the *Revue Médicale*, Nov., 1846.

SURGERY.

OPERATION OF MYO-TENOTOMY.

[There can be little doubt that in this, as in all other new operations, there is some risk of abuse, from the want of a due consideration of the cases to which it is safely applicable. It must therefore be a matter of interest to the surgeon, to know what are the veritable indications for its performance, and what are the cases in which mechanical means alone will prove sufficient.]

According to Neumann there is but one pathological condition which is indicative of the propriety of the section of tendons; this is *muscular retraction*. When this is not present, whatever be the state of the parts, the operation will not be followed by its expected results. The muscular retraction referred to manifests itself in general, by a tension and hardness of the tendon or its muscles, which cannot be accounted for by the state of the affected limb. We must be careful not to confound the *retraction* of a muscle, with a *shortening* of its fibres. To shew the importance of a due distinction of these conditions, it will suffice to glance at one of the affections for which tenotomy is most frequently employed, *pes equinus*. A man in perfect health is able, at pleasure, to induce such contraction of the gastrocnemii muscles as shall elevate the heel as much as is commouly seen in *pes equinus*. There is no proof, therefore, that the tendon is *shortened* in this affection; it is only *retracted*, and tenotomy destroys the morbid retraction and rigidity of the fibres, without necessarily causing the elongation of the tendon. And even if it did so, the elongation would be inconvenient, for although the patient would be able to place his heel on the ground, he would walk defectively. Again, it is necessary to separate *morbid retraction* of the muscles and tendons from that which occurs in the aponeurosis and ligaments, forming a real *shortening*.

Among the diseases which require tenotomy, and which depend upon muscular retraction, the author establishes two classes,—those which are general, or those which may appear indiscriminately in any part of the body, and those which are confined to particular localities. The first class includes paralysis and anchylosis, when these are accompanied by permanent retraction of the muscles; certain accidents to which the joints are subject, and which are always accompanied by muscular retraction, such as insensibility, sensation of cold, &c. In the second class he comprises strabismus, ptosis, tortuosities, club-foot, and articular retractions.

Another important question is whether, when several muscles are simultaneously retracted, they should be

operated upon at one or several different times. On this point the author is opposed to M. Guerin, and affirms that it is better to divide several muscles at once if they belong to the same region. If another articulation or limb requires an operation, it should, he observes, be always at an interval of a week at least from the former one.

The author farther states, that tenotomy should never be performed on infants under a year old. The operation for strabismus ought not to be recommended before the age of eight or ten years, as up to this time the resources of nature may prove sufficient. So also for club-foot, we ought never to operate before the age of twelve years, because previously to this age a cure may be accomplished by mechanical means alone. After the age of sixty the author thinks tenotomy useless. Inflammation of a retracted articulation is a potent contra-indication to an operation in all cases.—*Casper's Wochenschrift.*

OBSERVATIONS ON THE INHALATION OF SULPHURIC ÆTHER.

By E. Copeman, Esq., F.R.C.S., Coltishall.

Amongst the novelties of the day nothing has excited a greater or more universal degree of interest than the performance of surgical operations without pain. The reason for this is so obvious that it is needless for me to refer to it. Through the instrumentality of the press, both medical and general, facts are daily brought before the public which prove to demonstration, that by means of the inhalation of æther, the pain of a surgical operation may be avoided; and it is very probable that the wide diffusion of these interesting facts may lead to a trial of the effects of the vapour of æther, not only by surgeons, but also by some who are not educated to the medical profession. But it seldom occurs that a great good is unmixed with evil; and I believe it to be as much a duty on the part of surgeons to represent and warn against danger, as to relieve suffering, and cure disease. Upon this principle I lose no time in communicating the circumstances attending a trial of the inhalation of æther, on the evening of the 23rd instant, in my presence.

The experimenter was a medical gentleman, who requested me to extract a tooth for him, provided he could make himself insensible to pain by means of æther. He breathed the vapour for several minutes without any apparent effect, but soon afterwards thrust the apparatus *suddenly* from him, exclaimed that he could bear it no longer, staggered about the room, and was assisted to a chair. His breathing became very difficult; his arms were stretched out; his fingers extended; and he was perfectly cataleptic. I would then have attempted to draw his tooth, but he showed some resistance, and his breathing was so exceedingly laboured, that it would have been almost impossible to perform that or any other operation. Each expiration was accompanied with a loud *Hah!* his eyelids were closed; his head was hot; pupils not altered; conjunctivæ much injected; pulse 120; and his appearance altogether was so distressing as to excite great alarm in the minds of the bystanders. I applied cold to the head; gave some brandy and water, for his hands were cold; and admitted fresh air freely into the room. Soon the cataleptic symptoms disappeared, and were succeeded by severe hysteria, with about the same degree of consciousness as is usual in that disease. With some difficulty I led him to the outer door, when he exclaimed—"Cover my chest," "cold, cold, cold." He was then removed to the sofa, when he was seized with severe cramp in the legs, the difficult breathing still continuing. I gave more brandy and water; applied hot flannels to the feet, and cold water to the head; admitted fresh air freely, and watched the progress of the case with no little anxiety; for these distressing symptoms continued for *more than an hour*, during which time I had to contend against the most fearful apprehensions of the mother, as well as to administer relief to a near relative who had voluntarily taken a poison, the effects of which I had not before witnessed, and the probable result of which I could not from experience determine. At last a few deep inspirations ushered in a state of semi-consciousness, the patient raised himself to a sitting posture, and looked about him with a vacant stare, the conjunctivæ being very red and suffused. He attempted to rise, but tottered like a drunken man, and suffered a degree of exhaustion and giddiness which lasted until he was taken to bed. He slept well, but next morning complained still of languor. I should mention, that while he was lying on the sofa I applied strong ammonia to his nose, without its producing any visible effect, and he had afterwards no recollection of the circumstance.

The description afterwards given by the patient of his sensations whilst under the influence of the æther, was as follows:—He felt nothing for several minutes, but on a sudden appeared to lose all muscular power. He seemed to take leave of the external world, but experienced a dreadful sensation of universal tremor, and yet a perfect fixedness of the limbs. He felt irresistibly disposed to lie down, and get his head upon the ground; was much distressed with a sensation of cold; also of tightness across the chest; and although he seemed to be aware that persons were talking to him, had no consciousness of what was really passing around him. He said his sensations were so dreadful that he would rather undergo any amount of pain than submit to the same again, which he could compare only to a state of utter helplessness and impending dissolution.

The impression on my own mind was, that I would on no account willingly produce a similar train of symptoms; and that, if such were to be the *frequent* effects of the æther, there would be few who would wish to exchange for them the pain of a surgical operation.

The apparatus employed was a glass jar, with openings at the top, into one of which was inverted a flexible tube for inhalation; and into the other a funnel, containing a piece of sponge, saturated with æther. About an ounce of æther, and several pieces of sponge, were in the jar. The patient was 23 years of age, spare, and of nervous temperament, with a brain very active and excitable. The time at which the inhalation was performed was soon after dinner; I presume,

therefore, that neither was the constitution of the patient suited to the exhibition of æther, nor the time for the performance of the operation judiciously chosen. Certain I am, that it would have been extremely difficult to perform any operation requiring steadiness or delicacy in its execution during the presence of such symptoms as were produced in this instance by the inhalation.

It is clear that great judgment is required in the selection of cases, and that the inhalation of æther ought on no account to be practised by any but competent medical practitioners. The object for which it is employed is so desirable, that in all probability it will become general in the profession; but in order to be useful, *it must be safe*, and I trust the above narrative will prove, as it is intended to be, a warning against the indiscriminate employment of a powerful agent, which, in incompetent hands, or under unfavourable circumstances, is capable of producing very disagreeable if not *dangerous* effects.

Coltishall, January 25, 1847.

AMPUTATION PERFORMED UNDER THE INFLUENCE OF ÆTHER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

The result of operations performed upon patients under the influence of æther, will, for a long time to come, be regarded with peculiar interest both by the medical profession and the public; and it seems desirable that the practice of reporting all the cases which occur, whether favourable or otherwise, should be continued, as affording the best means of enabling us, in due time, to obtain a correct knowledge and form a just estimate of the real value of this highly interesting and, I hope, most happy discovery. I am consequently induced to send you a brief report of a case which I had at the Northampton General Infirmary, on Thursday, the 21st inst.

My patient, a little boy 12 years old, had for two or three years been the subject of scrofulous disease of his left knee. Treatment had proved useless, and his constitution had begun to feel the effect of local disease. Amputation therefore became the only chance of saving life, and to this both the parents and the patient were at length induced to consent. The means so happily discovered for preventing the pain of surgical operations not having been tried at this Infirmary, I determined to avail myself of this case for the experiment, and had arranged to call upon the parents and request their consent, but fortunately the mother, anticipating my wishes, waited upon me, and requested that either this or any other measure might be adopted if it could afford a chance of relieving her child from the agonies of the operation.

I thought it expedient to try the effects of inhalation the day before the operation; and I am inclined to attach some importance to this, believing that some cases of failure, which have been reported, might possibly have been successful, had such a measure of precaution been used. The little boy was at first rather alarmed, and, from the effects of agitation and apprehension, not able to breathe the vapour well, but by a little gentle persuasion and encouragement he soon succeeded in doing so, and in about two minutes the stupifying effect of inhalation was full and satisfactory. By various little means we assured ourselves that he was unconscious of pain. He was pleased when he awoke, and talked about his nice dreams, and, the next morning, when I went to him, a little before the time appointed for the operation, I found him quite cheerful, and apparently feeling confident that he should not suffer any pain. He said he should not be afraid this time, and that he would breathe it well. He did so, when placed upon the table, without any agitation; but the effects on this occasion were not produced so soon as the day before, which I attributed to his seeing so many gentlemen in the room, together with other feelings which might attend the occasion; but in about four minutes the state of unconsciousness appeared to be complete, and I proceeded with the operation,—amputation above the knee. The limb was removed in about two minutes, during which time not the slightest motion nor sign of sensation was observed; afterwards he became partially awake, and capable of conversation, but still seemed to suffer no pain from tying the vessels and dressing the stump. As on the day before he talked about his dreams, but most distinctly assured us that he had not been conscious of any suffering. All the medical officers of the Infirmary were present, and, with one or two exceptions, all the surgeons of the town, and some others, and every one was satisfied that the power of the vapour had been most fully and satisfactorily shown.

I attach no particular value to the apparatus I made use of, not doubting that many better ones are already in use, and that farther improvements will probably still be made; I merely mention, therefore, that it is a common wide-mouthed bottle, holding about one and a-half pint, fitted with a cork, which is perforated by two glass tubes. One of these, the breathing tube, goes in no farther than just through the cork; the other goes nearly to the bottom of the bottle, its lower end being immersed in the æther, of which about half a pint is required. This tube admits fresh air into the bottle as fast as it is drawn out by the breathing tube; and the said air passing through the æther, becomes strongly impregnated by its vapour. A piece of sponge is fixed at the upper part of the bottle above the æther; an elastic tube is attached to the outer orifice of the breathing tube, and to the other end of the elastic tube, a tin mouth-piece of two parts, one for inhaling out of the bottle, the other for exhaling, the latter tube requiring a simple valve.

I have pleasure in stating that my little patient, is going on in all respects perfectly well.

I am, Sir,

Your obliged and obedient servant,

H. TERRY.

OBSERVATIONS ON THE INHALATION OF SULPHURIC ÆTHER.

By Clement Hawkins, Esq., Surgeon, Cheltenham.

The introduction of a new remedy into the practice of medicine and surgery, at all times attracts great attention; and I am inclined to think many useful remedies often fall into disrepute and disuse, in consequence of the indiscriminate application of them.

Those members of the medical profession who have

had an opportunity of testing the efficacy of the inhalation of the vapour of sulphuric æther, in rendering patients insensible to the pain attendant on surgical operations, appear to have pronounced unanimously a verdict in favour of the discovery of Dr. C. J. Jackson, and Dr. Morton, in America. Such appears to be the case, if we may credit the accounts lately promulgated by the daily press. Dr. Bigelow, in the Boston *Medical and Surgical Journal*, has given a detailed account of the effects of this discovery in numerous cases. I have read carefully some extracts from his paper in the last number of the *British and Foreign Medical Review*, and I cannot consider the symptoms which accompanied the inhalation of the vapour altogether free from danger. In some, alarming cerebral symptoms occurred; one patient became excited, and required to be confined in the chair. "Young subjects are affected with nausea and vomiting, and for this reason Dr. Morton has refused to administer it to children."

A short time since, I witnessed the effects of this remedy on the person of a young medical man, of spare habit. He requested my attendance late in the evening to restrain a profuse hæmorrhage, consequent on the application of two leeches to his gum. I succeeded by the use of pure tannin. He informed me, that two days previously, the crown of a tooth had been broken off, in the attempts made by a dexterous dentist to extract it; this operation was followed by great inflammation, aggravated by exposure to cold; the pain he suffered was almost intoterable. The next day, contrary to my advice, he determined on having the stump removed. I cannot imagine a more painful proceeding, considering the state of the parts on which the operation was to be performed. He requested that I should be present, as he was about to inhale the vapour of æther previous to the attempt being made.

A bladder, with a suitable mouth-piece, &c., was prepared by Mr. Ruck, of the Montpellier Baths, in this town, and the sulphuric æther put in it. The patient proceeded to inhale the vapour; in two or three minutes he became quite unconscious; complete relaxation of the muscles ensued; the pupils were dilated; the pulse small and quick. The dentist, with an elevator, proceeded to eradicate the stump, which broke in the attempt. About one minute was occupied in performing the operation, when he started from the sofa, and commenced dancing and singing, placing himself in a pugilistic attitude, and made a desperate attack on a vapour bath which was standing in the room. The face and neck were much congested, and far darker than I have ever witnessed under any circumstances, the pupils enormously dilated. I must say I was relieved from much anxiety, when I saw the countenance restored to its natural state. I should think the whole period occupied in inhaling the vapour, and the return to consciousness, was not more than five minutes. The pain returned with great violence, and he again attempted to inhale the vapour, which proved a failure. Farther attempts were made to eradicate the offending stump in vain. I recommended him to go home and take a grain of muriate of morphia; in the evening he was free from pain. He informed me that although he felt no pain during the operation, he was not altogether unconscious.

I have thought it worth while to communicate the particulars of this case, and to make these observations on the use of this new discovery, and I hope the members of the Provincial Medical and Surgical Association will give a candid statement in the Journal of the effects of the remedy under consideration. Many I know have already operated under its influence, and it is very desirable we should have their experience faithfully recorded.

Dr. Ware, of Boston, in his letter to Dr. Forbes, in the *British and Foreign Medical Review*, says, "objections may arise, of which we do not dream, and evils may be found to follow which we do not now perceive," The violent gesticulations that ensuedin the instance I have detailed, although of no great importance in an operation unattended by hæmorrhage, would have been of serious consequence in one in which it was requisite to divide large vessels. I feel it would have been almost impossible to restrain the muscular exertions of my friend, who informed me that similar effects follow the inhalation of laughing gas.

If I were desirous of performing an operation under the influence of the vapour of æther, I should certainly make a preliminary experiment on the patient some days before the operation was to be done, and in the present state of our knowledge I should decline using it in cases of accident requiring amputation, &c. In plethoric subjects and in those who have a disposition to cerebral congestion, I should consider the use of the remedy wholly inapplicable.

REMOVAL OF A STEATOMATOUS TUMOUR UNDER THE INFLUENCE OF SULPHURIC ÆTHER.

Eliza Morris, a patient of the Chichester Infirmary, aged 29, the subject of a steatomatous tumour, situated deeply in the left lumbar region, and about the size of a goose's egg, was operated on on the 29th instant, in the presence of several members of the profession, whilst under the effect of sulphuric æther, by Mr. Abraham Duke, senior Surgeon of that Institution.

The patient having been placed in a proper position for the operation, and the nose being closed by an assistant, the inhalation was commenced, and in about six minutes it was quite evident that the vapour had produced the desired effect, (this was indicated by the turning up of the eyes, falling of the eye-lids, a fixed but dilated state of the pupils, the lowering of the pulse, and the total unconsciousness of the patient,) when the fingers were removed from the nose for a few seconds. Mr. Duke then began his first incision, and in three minutes the tumour was dessected out, without the patient evincing the least sign of pain, or any unpleasant effects supervening. At the commencement of the operation she moaned occasionally, and says she felt a slight prick, but not anything like pain; in fact she was not aware of having undergone the operation when placed in bed, twenty minutes after it had actually been performed. It was necessary to make use of six sutures, and although

so many were inserted no pain whatever was then experienced; this was the more extraordinary as she was then talking with those standing around her. No vapour was administered after the removal of the diseased part.

Numerous expensive and complicated apparatus have been invented for the inhalation of the vapour of æther, but in this case nothing but a common inhaler, with that portion of Reed's enema syringe containing the valves, introduced between the vessel and the tube, with an India rubber covering for the mouth, was used, and with the most perfect success. This is another very satisfactory instance of the great benefit to be derived from the use of the vapour of æther, and its valuable assistance to the surgeon in difficult and painful operations.

PERSPIRATION IN FEBRILE DISEASES.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In your number of January 27th, you report the proceedings of the last meeting of the Bath and Bristol Branch of the Association. In the discussion on fever which then took place, I am made to observe, "that the peculiar odour emitted in cases of fever was given out by the perspiration."

This certainly was the first observation I used, but I employed it merely as the test to introduce to the notice of the meeting, a more important one, to which a long experience in the treatment of febrile diseases had led me,—namely, that the period of infection in fevers and febrile diseases was that in which the perspiration was offensive in its odour.

The exanthemata plainly prove the part performed by the skin in the relief of fevers; we use a portion of the secreted matter to convey their infection; while in continued fever, as I maintain, this infection is propagated by the diseased perspiration, sensible by contact, insensible by inhalation.

I then took a wider range, and in relation to phthisis pulmonalis, said I had seen many cases where relatives previously healthy, and by no means predisposed, had become diseased in consequeace of their sleeping constantly with those affected by it, more particularly relating instances of husbands and wives, sisters, &c. The night-sweats in this disease have always had offensive odour, and are a diseased secretion; and the disease is infectious under this condition—namely, by contact, and not by inhalation, for nurses and others rarely receive it, and it is from this circumstance that it has neither been considered neither infectious nor contagious.

I proceeded farther to remark, that in rheumatism (a specific disease of a febrile character, attended with offensive perspiration,) I had seen relatives in close attendance attacked with febrile symptoms, complete in every respect excepting the specific characters of rheumatism, while *hired* nurses altogether escaped.

This subject, an interesting and highly important one, is worthy of farther investigation, more particularly in relation to the health of the community, and the prevention of disease. I am well aware that many theories have been put forth to account for the contagion of fever and diseases of a febrile character; into these I have no time now to enter; but I would reiterate, that when diseases are accompanied by unhealthy cuticular exhalation, they are more or less contagious,—that the skin is the organ from which infection is received. Leaving the subject for further inquiry, anxious only, that what appears a trivial and tyro-like observation, should be explained by its sequence of practical remarks,

I am, Sir, your obeedint servant,

JAMES TUNSTALL, M.D.

Bath Hospital, January 30th, 1847.

Medical Intelligence.

OPERATIONS PERFORMED UNDER THE INFLUENCE OF ÆTHER.

Among the more remarkable operations performed at the metropolitan Hospitals under the influence of the vapour of sulphuric æther since our last, are one of Cæsarean operation, by Mr. Skey, at St. Bartholomew's Hospital; and one of lithotomy, where the bladder was diseased, and in an extremely irritable state, by Mr. Arnott, at the Middlesex Hospital.

The following are some of those which have been performed in the provinces:—

At Liverpool, at the Northern Hospital, by Mr. Stubbs, amputation of the thigh, for diseased knee-joint; at the Eye and Ear Infirmary, by Mr. Neill, for hard cataract by depression, in two cases, for soft cataract by breaking down the cataract, and for strabismus.

At the Northampton Infirmary, by Mr. Terry, amputation of the thigh.

At Cheltenham, by Dr. Brookes, removal of the breast.

At Sheffield, by Mr. Beckitt, removal of the middle finger and a portion of the hand.

At the Suffolk General Hospital, Bury St. Edmunds, by Mr. Image, removal of a tumour from the breast.

At Lynn, at the West Norfolk and Lynn Hospital, by Mr. T. Bullen, removal of a scirrhous mamma.

At Maidstone, at the Kent Ophthalmic Institution, by Mr. Woolcott, removal of a tumour from the back of the neck; fistula lacrymalis; and strabismus.

At the Newcastle Infirmary, by Mr. Potter, for fistula; and in a case of diseased bone.

At Bristol, by Mr. Lansdown, removal of a cancerous tumour from the lip; of a portion of nail from the great toe; and amputation of the leg.

At Laxfield, Suffolk, by Mr. Beales, for lithotomy.

Mr. Cotton, of Lynn, has employed the æther vapour in private practice. He says,—"In one case the most perfect composure and serenity was preserved, during a painful operation; whilst in a second case, the most boisterous, hysterical-like spasms (as observed by Professor Parker,) followed, requiring all the force of the by-standers to hold the patient; a farther inhalation, however, effected the required degree of unconsciousness, and the operation was completed without the patient's knowledge, or the slightest indication of pain."

In Edinburgh the inhalation of the vapour has also

been successfully employed by Professor Miller, at the Royal Infirmary; and by Professor Simpson, in a case of difficult labour, a notice of which we extract from the *Edinburgh Weekly Journal*:—"A few days ago Professor Simpson stated to his class that he had practised, with entire success, the inhalation of sulphuric æther in a case of the most difficult form of labour, and where, otherwise, the sufferings of the patient would undoubtedly have been extreme. The mother was lame and deformed. At a former accouchement the labour lasted three or four days; and, from the necessarily protracted use of instruments, the patient's agonies were very great. On the present occasion Dr. Simpson had previously determined to avoid, if possible, the use of all instruments, and to attempt to extract the infant by the feet. He expected to be aided in this by the use of the æther inhalation. Accordingly, when labour had set in for a few hours, the patient was put under the influence of æther, and in a few minutes the child was turned and extracted, while the mother was altogether unconscious of the operation, and that, too, although the delivery was rendered excessively difficult, by the degree of compression to which the child's head required to be subjected. On afterwards awakening, or passing from her 'ætherealised' condition to the state of common consciousness, one of the first circumstances of which the patient became aware was the noise attendant on preparing a bath to resuscitate the infant. A remarkable circumstance pointed out in the case by Dr. Simpson was, that whilst breathing the æther the labour pains or throes continued, and yet the mother (to speak paradoxically,) *felt* no pains. We hear she is rapidly recovering, and was dressed and walking about the house on the fourth day, while on her last confinement she could not leave her bed for four or five weeks."

In Paris, operations have been performed under the influence of æther at the Hôpital St. Louis, by MM. Malgaigne and Velpeau, and at La Pitié. The following is an extract from a private letter, in reference to the practice:—

"Operations have been lately performed upon four patients at La Pitié under the influence of the inhalation of the vapour of sulphuric æther: three of the cases succeeded most satisfactorily, but in the fourth, the usual pain was felt, owing, it is supposed, to the patient not having inhaled a sufficient quantity of the vapour. There are discussions here and differences of opinion, as to the propriety of using this prevention against pain, and the general impression is, that it is inadmissable in cases where violent re-action and excitement of the circulation would be dangerous after operation. Farther experiments, however, are to be made, and the matter is likely to be referred to the Academy of Sciences."

DEPUTATION TO SIR GEORGE GREY.

On Friday, the 5th instant, a Deputation from the Council of the National Institute of Medicine, Surgery, and Midwifery, was hououred with an interview by the Right Honourable the Secretary of State for the Home Department.

MEDICAL APPOINTMENTS.

James Paget, Esq., of St. Bartholomew's Hospital, has been appointed Profossor of Anatomy and Surgery to the Royal College of Surgeons, in the room of Mr. J. F. South, resigned.

Dr. William Pulteney Alison has been appointed First Physician to Her Majesty the Queen, in Scotland, in the room of Dr. J. H. Davidson, deceased. Dr. Robert Christison has been appointed one of Her Majesty's Physicians in Ordinary, in Scotland; and Dr. James Yarde Simpson has been appointed Physician Accoucheur to Her Majesty, in Scotland.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, February 7th, 1847:—R. A. W. Westley; J. K. Baines; W. S. Briggs; E. Govett; J. L. Palmer; J. Harward; M. Morris; C. Downes.

HUNTERIAN ORATION.

The Hunterian Oration will be delivered on the 14th February, in the Theatre of the College, by Joseph Henry Green, Esq.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, January 21st:—George Wilmshurst, Warwick; Wm. Sutherland Meek, Nantwich.

OBITUARY.

Died, January 8th, aged 66, James Ferris, Esq. Surgeon, Truro.

January 15th, at Calais, at a very advanced age, Midford George Leroux, one of the oldest members of the College of Surgeons. In early life he was Staff-surgeon in India; but his love of travel induced him to leave the service and visit countries in all quarters of the globe. About forty years ago he settled at Clifton, near Bristol, where his varied attainments soon secured an ample practice. Becoming the subject of asthma, he withdrew from professional life and resided chiefly abroad; but his zeal to keep pace with the progress of science was unabated by physical infirmities, and he preserved to the last the character of an accomplished surgeon and gentleman.

January 22nd, at Burton-on-Trent, aged 76, John Spender, Esq., M.D.

January 25th, at Denmark Hill, Surrey, aged 27, John Buxton, Esq. M.D.

Jan. 30th, at Ryde, aged 44, A. T. S. Dodd, Esq., Surgeon Extraordinary to Her Majesty, formerly Surgeon to the Infirmary, Chichester

Feb. 2nd, at Bristol, aged 89, Gawen Ball, M.D.

Lately, Isaac Raines, Esq., M.D., Burton Pidsea, near Hull.

ERRATUM.

TO CORRESPONDENTS.

Communications have been received from Dr. W. P. Brookes; Dr. Jeffreys; Mr. G. F. Wills; Mr. Banner; Mr. A. Napper; Dr. Cullen.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

A LECTURE ON PUBLIC HEALTH.

By Charles Hastings, M.D., F.G.S., Physician to the Worcester Infirmary.

(Read before the Worcestershire Natural History Society, January, 1847.)

The importance of paying serious attention to the questions which are involved in the consideration of public health cannot be well overrated; the most casual observation must shew us that we are continually affected by the objects which surround us, and that it has pleased the Almighty to place us on this earth for a brief season, and that our life, and health, and happiness, are day by day dependent on a variety of circumstances, over which it has pleased his Maker to give man some degree of controul. The health, therefore, and length of life of any community are in some degree dependent upon the adaptation of their existence to the laws by which it has pleased Providence this world shall be governed.

The volume of Nature lies open to all, and especially to the medical philosopher; in all regions he is excited to peruse her pages, to interpret her language and explain her laws. In the expeditions, whether of discovery, war, or commerce, made to remote parts, and to every climate of this earth, we see the utmost variety in the condition of mankind. It seems to me that a spirit of inquiry into the actual phenomena going on in this globe is congenial to man, and this disposition should be encouraged and directed to the acquirement of a more precise knowledge of every country and people.

If, in the small space occupied by Great Britain, no variation of climate, properly so called, is to be found, some difference of temperature certainly there is between the coasts of Cornwall and the bleak hills of Cumberland; some diversity of elevation and depression of surface from the summit of Snowdon to the low lands of Cambridgeshire. These accidents of situation, connected with habits of life, influence health in no inconsiderable degree. It is a popular notion that the greater the elevation the more perfect the state of health. The mountaineer is commonly characterized by a robust energy of frame and length of days, denied to the inhabitants of vallies. But the scientific inquirer will refer to a number of circumstances to account for this privilege. This happy state of exemption or partial exemption from disease, will depend much on modes of life;—on diet, exercise, and temperance;—on employments, whether sedentary, manufacturing;—solitary or gregarious;—mining, chemical processes, or agriculture. But all experience goes to establish the fact that a country life is more favourable than a town life to health and longevity.

The question which modern science has to solve is, whether there is not some means by which the unhealthiness of the inhabitants of towns may be averted, and by which they may be placed in a similar position, as to the duration of life, as their, in this respect, more fortunate brethren in the country.

Mr. Chadwick, whose practical experience in the inquiries which have relation to public health is very great, thus speaks to this question in his report to the City Commissioners of Worcester:—

"There appears to be no sufficient reason for not believing that it is within the reach of practical measures to bring the health of the population of Worcester, up to that enjoyed in Tenbury, Martley, and Upton-on-Severn.

"Now, what is the loss of health and life in Worcester as compared with the loss of life experienced in the Tenbury district,—a district not freed, as many public establishments are, from the ravages of epidemics, and therefore not affording a very high standard!

"According to investigations, founded on the largest experience, the proportions of the deaths of infants to the deaths of adults, are the best tests of the sanatory condition of a population, because infant life is the most dependent on atmospheric purity, because the infantine mortality is the least affected by the migration or emigration, or the occupations of the adult population.

"Now, it appears from the Registrar General's annual return, that whilst out of every hundred children born alive, at Tenbury, and the surrounding district, eleven died within the year of their birth; at Worcester, no less than twenty-one died within the year of their birth. Had this increased rate of mortality at Worcester during that year, been in the same proportion as in the Tenbury district, there would have been 151 deaths fewer; if the rate of births had been at the same rate as in the Tenbury district, there would have been 35 births fewer to make up the deficiencies of the increased mode of mortality. In the latter district, the average age of all who died was 41 years and four months, and the average age of all the adults, all above twenty, who died during that year, was 59 years and six months, or nearly three-score years; whilst in Worcester the average age of all

who died was 33 years and four months only; and of all who died above the twentieth year, 56 years and seven months only. Upwards of 31 per cent. were cut off in the prime of life before the natural and insurable term as ascertained in the adjoining district,—that is to say, between 20 and 60 years of age. One with another, each adult who died during that year, lost two years and eleven months of healthful life and working ability, as compared with the durations of adult life in the Tenbury district. The loss of life lost to each individual in Worcester is, therefore, not less than eight years; in other words, supposing that the same proportionate rates of mortality obtained in Worcester as in the Tenbury district from year to year, as there is every reason to believe there would, then the duration of life to every individual born and reared in Worcester, is one fifth less than it would be."

During the whole course of my medical life, and my residence in this city, which now extends to nearly thirty years, the question of the state of the public health of its inhabitants has repeatedly engaged my attention, and it will, I am sure, be in the recollection of many members of this Society who now hear me, that I have, on several occasions, pressed it on their notice. Happily I can now do so under more promising circumstances than formerly, for the endeavour to improve the social condition of the town-population is no longer confined to individual exertion. I may congratulate myself and you, that what a few years ago was almost confined to a few members of the medical profession, has now become a national movement, and that the Government of the country, seeing the immense importance of the improvement of the health of towns, have issued commissions of inquiry, and have thus obtained a great mass of valuable information, which will enable them to legislate with security on this complicated and difficult subject.

Besides which, associations have sprung up supported by the most influential of our countrymen, having for their object the exposition of the causes which operate so injuriously in our large towns, not only on the health and longevity of the inhabitants, but also on their religious and moral improvement, for it cannot be doubted that an incalculable amount of demoralization is attributable to the same causes.

It is, however, a great mistake to suppose that either the possession of wealth, or immunity from labour, are the points which make the difference in the degree of health. The rich man's abundance may expose him to as many diseases arising from excess or indolence, as those which beset the poor man owing to hard fare or scanty clothing. Let the labourer but have a decent house built on a dry soil, well drained, and with all its putrefying refuse properly removed,—let his dwelling have at least two bed-rooms above the ground-floor, and let it have a good supply of pure water and fresh air, and there is evidence to show that he is as likely to enjoy health and length of life, supposing that similar attention is paid to the place in which he does his work, as the most wealthy of his employers. The truth of the above remark has been amply attested by the Report of the Health of Towns' Commission, and it is highly encouraging, as proving that the evils of poverty and sickness which at present weigh down our town-population, admit of great amelioration if the means applicable thereto be philanthropically and energetically employed.

I shall not, however, indulge farther in any general remarks, but engage your attention in considering very briefly some of the circumstances in the city of Worcester which have reference to the public health of the inhabitants. The city of Worcester is one of the most ancient in England, and some of its buildings, although they attest its antiquity, are on that very account not very favourable to health. Its situation is inland, the distance from the nearest sea-coast being about sixty miles. The elevation of the city at the Cross above the sea, is about seventy feet, and the elevation at the Cross above the bed of the Severn is about forty feet. This elevation extends along High Street and Foregate Street, and is to be noticed as affording the opportunity of an easy drainage of a great part of the city into the Severn. The relation of the river to the city is particularly worthy of attention; many of the houses are built upon its banks, and we have now a rapid flowing stream, eight feet deep, continually assisting, by creating a current, to ventilate the streets, and to carry away all impurities. The late improvement of this noble river appears to me highly favourable to the health of the inhabitants, as substituting a full rapid stream for what was formerly in many parts, for portions of the year, little better than a stagnant ditch, with many impurities during the summer season decomposing in the bed of the river. It is much to be regretted that many houses are built upon land liable to be inundated by floods, for not only are the inhabitants of those houses subject to great inconvenience, but I fear on many occasions their health suffers severely.

The appearance of the principal streets of the city is striking, and they are broad and wall paved; but almost all the minor streets, especially those between the High Street and the river, are narrow, and deficient in cleanliness and ventilation.

I may say also, that there has been great inattention to the health of the inhabitants, in fixing upon insalubrious portions of ground for building upon. That portion of the city called the Blockhouse, was, until lately, positively an undrained marsh; and the sickness that for some years prevailed among the inhabitants was very great; but a few years ago an act was obtained to improve the drainage of this locality, and a large sum of money was expended in a culvert, which has greatly improved the land, and has also tended to lessen the mortality of the inhabitants. As on all similar occasions, where it has been necessary to make a rate for raising money for such purposes, a great outcry was made against the promoters of this public improvement; but, independently of every other consideration, the public funds have been benefitted by this outlay, inasmuch, as many a father who would otherwise have met an early grave, by fever or other disease, has been spared to bring up his family in comfort, instead of leaving them a burthen to the

parish. It were well if the system of drainage throughout other parts of the town were as efficient; but I am sorry to say that the substitution of cesspools for drains is a prevalent custom. This is indefensible, for the situation of the greater part of the city is well adapted for perfect sewerage.

I can quote the high authority of Mr. Austin in favour of the advantageous position of Worcester, in respect to drainage. In his very valuable report made to the City Commissioners he says, "The city, moreover, whether fortuitously or not, is so constructed as to present an opportunity, rarely if ever met with, for obtaining a most perfect system of sewerage, without difficulty of any kind, and at comparatively trifling cost, if properly and comprehensively laid out. So much indeed was I struck with this peculiarity, that I would almost venture to state it as an impossibility, that any town in the kingdom could present an equal area that could be more adequately sewered at less cost. For the most part substantially constructed, the thoroughfares are laid out in good and direct lines, the main traversing the thoroughfare—the continuous line Foregate Street, Cross Street, and High Street—forming as it were the ridge or hog's-back of the whole city, from which the diverging thoroughfares, short and at frequent intervals, fall in both directions with ample declivity into lower grounds, which have their outlet in the river Severn."

When we consider that even of late years some of those who have erected houses and buildings in this city have, in many instances, paid scarcely any attention to have the site healthy, and the houses after they are erected well drained and ventilated, we cannot but anxiously hope that the expected legislative measure will contain some compulsory provision under which all future buildings shall be, as far as possible, provided with these necessary requirements, and also some security against the crowding together of large masses of the community in pent-up cellars and other unsuitable dwellings.

But, in looking at the condition of the habitations as affecting health, the transgression of its laws is by no means confined to those inhabited by the poorer classes. Many of the country houses in England are surrounded with circumstances unfavourable to health. They are not uncommonly placed on a gentle acclivity, on the edge of a marsh, and, for the sake of the prospect, exposed on that side, although it may be the east or north; whilst on the other side, where the ground rises, and is more diversified, they are thickly enclosed by trees, frequently being laid open on one side to malaria, and fenced in on the other by hills, woods, shrubberies, garden hedges, or high walls and stables. They become perfect boxes of malarious influences, and are either repeatedly visited by fever, or are the unsuspected cause of declining health of several individuals of the family, for malaria when it does not produce fever, seems in numerous instances slowly to derange the digestive functions, and gradually to undermine the whole health.

After this digression, regarding country houses, I shall not at present farther remark on those circumstances which affect the public health of the inhabitants of Worcester, but I shall now adduce some records of the population of this ancient city, so as to make a comparison between the mortality of late years and that which prevailed in earlier times. In doing this, however, we shall find difficulty in going far back to make any safe deductions, for I have no doubt you are all well aware that our population returns previous to the year 1800 are very imperfect. Since that time a census has been taken every ten years, and from these public documents accurate information may be gleaned; besides which, within the last few years, the Registrar General has published quarterly statements of the mortality in different districts, which will go far in after-times in pointing out the tainted spots, and show in what parts of the kingdom certain diseases destructive of our population most prevail.

The population of Worcester previous to the year 1800 is very inadequately reported. We possess the aggregate number of the inhabitants for two or three distant periods, yet, on this number we cannot depend with any certainty, for if we apply to the parish registers wishing to discover the rate of increase or decrease, such is their incorrectness and incompleteness, that all reasoning from them would be inconclusive.

The whole population of Worcester is stated by Bishop Sandys, during the reign of Queen Elizabeth in 1563, to have amounted to about 10,025, and this population being contained within the old city walls must have been very crowded. We are not then surprised to find that in the following century in 1646, disease had thinned them considerably; and this was found to be the case, for in that year, when the Parliamentary forces surrounded the city, the population only amounted to 7176, and even when the garrison and train bands were added, the numbers were little more than 9000. In those evil and troublous times, we cannot be surprised that the population retrograded. A check must necessarily have been put to trade and manufacture, and the sword did its part in slaying many of the most vigorous of the population. There is no question that the oscillation of the woollen manufactory, once employing so large a portion of the population of this city, had much to do in by-gone times in causing a fluctuation in the number of the inhabitants. In the plan of the city, published by Mr. G. Young in 1779, he gives the number of the inhabitants at 13,104, being an increase of 5000 since 1646, and of 3000 from the reign of Queen Elizabeth.

When we come to the population returns in 1800, we find the population including the suburbs amounting to 13,589; in 1810, to 19,759; and in 1821 to 25,834. In the returns for 1831 and 1841 there has also been some increase, but during the last twenty years there has been a less rapid increase of the population, owing probably to the generally depressed state of the glove-trade, which formerly engaged large numbers of the population. The number of the inhabitants in the city and immediate suburbs of Worcester, does not now, I believe, reach 30,000; so that whereas, from 1800 to 1820 there was an increase of 12,000 in the population, from 1820 to 1846 a

period of twenty-six years, it has not increased more than 4000. It may here be remarked, that the number of houses, in proportion to the inhabitants, has increased since the commencement of the present century, and we may therefore infer that the population are much better housed than they were during the last century.

This certainly is favourable to health, and it is evident that this, with other causes, has been latterly operating so as to improve the public health of Worcester; for this increase of population appears rather to have arisen from the decrease of the number of burials than from any other cause. I infer this from the facts exhibited by the population returns for the last forty years. In the beginning of that period the ratio of burials to the whole population was much greater than at present. The ratio stands thus for the three first decennial periods. In 1801 it was as one to thirty-two. In 1811 as one to forty three. In 1821 as one to forty-eight. Mr. Chadwick, for 1841, makes it as one in forty-four, but again in 1845, according to the returns of the Registrar General, the deaths were as one to forty-eight, taking the population at 28.000.

This result is encouraging, as shewing that since the commencement of the present century, although Worcester is larger and contains nearly double the number of inhabitants, it is become more healthy and more favourable to the prolongation of life. To whatever cause this is to be attributed the fact is such, and it proves that this city exhibits bills of mortality, in which the average number of deaths is smaller than in most other cities of the same population.

If we consider this circumstance in its true light, it is very encouraging to perseverance in the philanthropic efforts that are now making to improve the health of towns; for there was a period not far distant, when Worcester was particularly subject to fever, and in looking into Green's "History of Worcester," you will find that during the two last centuries pestilences have repeatedly visited the city, and have carried off large numbers of the inhabitants. My old and respected friend, Mr. Rayment, who practised for half a century in Worcester, thus writes in relation to the prevalence of fever:—"In 1781 the city and suburbs of Worcester were reported much subject to fever. If we consider the wretched state in which many of the lower classes of the inhabitants then lived and were crowded together in the remains of the former clothing manufactories, the neglected state of the streets in which these dwellings were situated, the open state of the drains in the best streets, the frequent stagnation of their contents giving rise to an impure state of the atmosphere, and these impurities increased by large quantities of decaying animal matter proceeding from the glove manufactories, it appears very probable that these local circumstances made more active the sources of fever." Now, it is desirable just to contemplate the altered state of Worcester as respects health since the time above specified. In 1781 we have the most undoubted evidence that about one out of thirty of the inhabitants died annually. At the present time only one out of forty-six of the inhabitants die annually. Now, let us ask, to what is this improvement owing? I answer, to the exertions that have been made to improve the health of the city.

Credit is due to the City Commissioners for many improvements in the sanatory state. Imperfect as our drainage still is, we have no open drains. Nuisances, although prevalent, are not so noxious as formerly.

The inhabitants too are now better lodged and clothed than formerly. Upwards of two thousand new houses have been built within the last forty years; and although too many of them have been placed in unhealthy spots, yet the manner in which the rising grounds surrounding the city are now studded with single houses and rows of houses, shews that attention has been paid to erect dwellings for the rich and poor, in the elevated, dry, and airy situations. But much remains to be done before this city is placed in the position as to its public health, which it may occupy, if due exertions are made to carry out those sanatory measures, which I verily believe will, at no distant period, be adopted by the legislature. I shall therefore conclude by offering some suggestions as to the nature of the improvements to be wished for.

First, then, I shall mention as deficient, the supply of river water. With so noble a stream passing so close to us, every poor man, as well as every rich man, ought to have an abundant supply of water. Every sanatory consideration points out this as desirable; and fortunately, modern science has shown that this may be done at a very reasonable rate. At Nottingham an abundant supply of water is afforded to each workman for a penny a week. I wish it was so with us.

How indispensable too are baths to the health of a large community; and yet, hitherto, how ineffectual have been the efforts of those who in Worcester have advocated their establishment! So listless indeed have my fellow citizens been in this matter, that I verily believe no public baths would have been established in our day if an act of Parliament had not come to our aid, by which instrumentality we now hope it will be accomplished.

With regard to the water of Worcester supplied from the wells, such is the prejudice entertained against it by some individuals, that you might suppose it was the source of much disease. This, however, is not borne out by facts. Worcester, as you are doubtless aware, is built upon gravel, and the stratum of gravel varies in depth probably from ten to twenty feet; immediately under the gravel lies the red marl or new red-sand stone formation, in which a considerable quantity of lime is found. It follows that the water percolating through the marl becomes impregnated with the salts of lime, the lime being found in combination with the carbonic, sulphuric, and muriatic acids. The incrustations on the pipes used for conveying water, and on the tea-kettles used for boiling it, consist principally of carbonate of lime, and attest that the water holds a large quantity of lime in solution, or so much of it would not be so readily deposited. On evaporation I have found many grains of this earthy-saline deposit in a gallon of water. Dr. Lyon Playfair states the amount

to be as much as fifty grains in a gallon, and I have not found the quantity vary much in several specimens taken from various parts of the city and suburbs. The so-much admired water at Henwick Hill contains a large portion of solid contents, and the circumstance of its containing a large impregnation of carbonic acid gives it the freshness for which it is admired.

The water in Worcester is improved of late years by the deepening of the wells. Until within the last few years most of the wells were only about fifteen feet deep, and the inhabitants were dependent upon the springs in the gravel for the supply of water, which, from the shallowness of the wells, was often mixed with impurities. Since the large drain in the Blockhouse was made, many of the superficial wells have become dry, and this has compelled many persons to sink into the marl for a spring of water. This, although productive of inconvenient expense, to many parties will be found of benefit, by giving a more abundant supply of water.

On the whole, then, I can dispel the alarm of those who are afraid of the water of Worcester directly causing disease by its saline impregnations; but a great evil results in an economical point of view. So hard a water is scarcely applicable for washing purposes, and it is also objectionable in tea-making, and for culinary purposes. I think it right, however, to warn you of a danger of another kind, arising from the prevalence of the custom of using lead for vessels holding water, and for pipes conveying it. This custom of using leaden pipes for conveying pump water has been, in some degree, sanctioned by science. It has been asserted with truth that water containing saline matter does not readily dissolve lead; but facts are stubborn things, and so far back as the time of Dr. Wall, that distinguished physician pointed out instances in Worcester where leaden pipes had been corroded by the action of the water.

This subject was taken up at the late meeting of the British Association, at Southampton. Mr. Osborne adduced facts to prove that it is desirable to avoid the use of lead in cisterns for receiving water, and also in pipes for conveying it. The result of his experiments seems to show that the presence of chlorine in the water of the New Forest is one cause of that water dissolving the lead. He also discovered other solvent principles.

Now, I have reason to believe that the Worcester springs of water not only contain chlorine, but also carbonic acid; and practically I find my suspicions of lead being dissolved by many of the springs of water in Worcester, confirmed by inquiries amongst the plumbers. They tell me that the leaden pipes connected with some of the wells of water remain for years, and are not at all corroded; whilst there are many of the wells of water that are so actively solvents of lead, that they are not unfrequently called upon to repair pipes which are corroded by the action of the water upon them. It is fearful to think that this lead so dissolved is carried by means of spring water into the human system, and becomes the source of insidious and intractable diseases; such diseases often elude the skill of the physician from ignorance of the cause which has produced them. It behoves, therefore, all who value their health to consider this, and if they have leaden pipes or leaden cisterns for their spring water, to ascertain, without delay, whether it is of such a nature as to dissolve the lead.

As the over-crowding of the poorer houses in a city is a frequent cause of disease, we should endeavour to improve Worcester in this respect; for although the number of inhabitants to each house is diminished since the commencement of the present century, being now not quite five to each house, and although many new houses have been erected for them, containing better accommodation, and are better situated as to dryness, warmth, and ventilation, yet those inhabitants who live in the old parts of the town, which were formerly the seat of the woollen manufactories, are not well provided with means of removing the filth which accumulates in them. The lodging houses especially are very dirty, and the average number of inhabitants is excessive, and the means of ventilation are very deficient; so that the effluvia and other causes here operate with intensity, so as in seasons of predisposition to this class of affections to be productive of contagious diseases. The mode in which the streets are laid out—their width or compactness—their pavement—their drainage—their exposure to the sun and to the wind, are considerations of much importance. The difference of a few paces may make a very considerable difference to the health of the inhabitants; thus at Rome, certain streets, nay, certain parts, sides, and even houses of some streets, are more damp, chilly, and exposed to the malaria than others. Certain parts of our own city have, until lately, been remarkable for fever; the Blockhouse-fields especially so, until the large drain was constructed. There are again other parts of Worcester where the dwellings are very old, and masses of building are accumulated together, which prevents ventilation and the access of the solar influence. There is no doubt that the inhabitants of these parts would be more healthy, if many of the old walls and masses of houses were pulled down, and thus open spaces occasioned where the air may circulate more freely, and as it were, percolate these districts.

I have no improvement, except as to drainage, to suggest in our principal streets; they are wide and well ventilated, and whenever a gust of wind comes it thoroughly perflates them, and removes impure exhalations. These exhalations, I am sorry to say, often arise; for the drainage, even in our principal streets, is yet very imperfect. The sewers, if they can be so called, are superficial, and are not constructed on any general and comprehensive plan. All this must be remedied before Worcester can derive, in point of health, all the benefit for which its natural situation appears to have destined it.

Mr. Austin, in his report to the City Commissioners, has submitted to the city a proposition for a most effectual system of sewerage, by which most of the evils arising from deficient drainage we have so long had reason to complain of, may be removed. Great

indeed, therefore, will be the disappointment, if the faithful city should not arouse itself, put forth all its energies, and carry out this necessary hygienic improvement.

There are several other points to which, if there were time, I should allude more fully, but to which I shall now only cursorily direct your notice. It is placed beyond all contradiction that the state of the grave-yards within our cities is a frequent source of disease, and Worcester is open to this evil. The difficulties that have opposed themselves to better sanatory arrangements in this respect are great; but let us hope that cemeteries without our cities may gradually become the approved mode of sepulture by all classes of the inhabitants, and we shall then reap the reward in improved public health.

The slaughtering of animals is another evil which calls for a remedy, as does also the keeping of animals, as horses, pigs, dogs, &c., which a better system of police would render less noxious to the inhabitants.

The clothing and diet of the humbler classes are of much importance. Worcester is not subject to those great vicissitudes to which large manufacturing towns are liable, and consequently the labouring population are not so much affected by them, their prosperity never being very great nor their adversity so appalling. A corresponding condition of their food and clothing is the result.

Vegetable food and tea are in great request, and the failure of the potato crop has been a source of difficulty. I shall not, however, here dilate upon this, but I may remark, that the causes producing disease in the vegetable kingdom, seem also coincidently to have affected the animal. Epizootics amongst horses and cattle have been observed in many places, and the reports of the Registrar General for 1846 shews an increase in the mortality, so that in fact, whilst we are planning and considering what can be done to diminish the insalubrity of towns, Providence sends a visitation which tells us that all our endeavours without his concurrence are vain. For some years past there was reason to believe that the causes of mortality in towns were less operative. The Registrar General in his report for 1845, says, in the last three years the price of provisions was cheaper, the commerce and manufactures of the country were more active, the relief to the destitute more liberally administered, and the wages of artisans higher; and all these circumstances favourable to public health undoubtedly contributed to the reduction of the mortality observed. In the midst, however, of all these pleasing prospects, in 1845 and 1846 there is a visitation of a blight in the potatoes and other vegetable productions,—and what is the result? Why in 1846 epidemic disease to a considerable extent prevails in the three kingdoms; the mortality has increased, and in many parts has been one fourth, and one third, and in some instances double the amount of former years.

Worcester has been leniently visited, and the epidemic affection has been lighter than in many parts, qut still enough has occurred to show that epidemic visitations will come, and that they fall most heavily where the laws of public health are most neglected.

This, then, is our encouragement. Providence puts within our power certain means of prevention. We know them. They are plain before our eyes. Shall we, then, be indifferent to these things? Is our life so long that we can afford to lose a considerable portion of it by neglect? The future must answer these questions. Hitherto indifference to these matters has been abundantly evident amongst all classes.

I feel that I have occupied more time than the nature of these meetings will well allow, but you will excuse me if I have delayed you too long, when you consider that the subject on which I have been addressing you is one in which, as Christians, and as men, we are all deeply interested; for however great may be the honours of those who by brilliant exploits add to the glory of their country, few will deny, that those deserve well, and contribute to her political welfare, who add to the health and happiness of the poor, who are always the mass of the community. Depend upon it, whatever tends to exalt *them* in the scale of moral and rational creatures, tends also in the same degree, to exalt the nation, of which they must always form the largest part in political power.

None but those who are in the habit of mingling with the lower classes can have a notion of the intimate connection which exists between physical and moral degradation. From religious motives alone *then* we may insist upon the necessity of endeavouring to improve the condition of the poor, and we should never weary in our efforts to induce the Legislature to devote their energies to this matter.

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(*Fourth Series of Experimental Researches.*)

By William Addison, M.D., F.R.S., Malvern.

(*Continued from page* 62.)

III. Embryo and Adult Textures.

The microscopical researches of Dr. Martin Barry and others have established the fact, that the first texture of the human embryo and its appendages is *corpuscular*, or incoherent cellular,—that is to say, a texture composed of cells or corpuscles, which have exceedingly thin walls, are very soft and brittle, having but a slight coherency. These cells have many analogies with the cells of the cellular textures of vegetables,—with the protoplasma cells of Mohl, in preceding all the solid formations, and containing a viscous colourless mass, mixed with granules or molecules, and with the incoherent chlorophylle cells of a leaf, in containing a material essential to the growth of the future and more important parts of the structure, in both cases, the material being a secreted or elaborated one.

When the embryo is growing, the transparent membrane or *amnion* formed around it is first

corpuscular, then *coherent cellular*, and then *fibrous*; and the walls of the blood-vessels ramifying upon it, undergo the same changes; they are first *corpuscular*, then *cellular*, and lastly *fibrous*. This then is the order of the morphology, in respect of the membranous envelopes of the embryo,—viz., first corpuscular, then cellular, and then fibrous. In the embryo itself, a month or five weeks old, and half an inch in length, several textural groups, representing the head, eyes, and extremities, the spinal column, liver, and heart, may be discriminated. All these groups, when examined with the microscope (700 linear,) are found to consist wholly of incoherent cells or corpuscles, soft and easily separable from each other; and they are all filled with a *protoplasma*, a viscous colourless matter, mixed with molecules. At this early period, nothing resembling a coherent cellular texture can be found; all is soft, pulpy, and brittle; there are neither blood-vessels nor fibres, nor can anything hard or coherent, resembling cartilage or bone, be detected. When the embryo is four months old and seven inches long, the brain, liver, &c., are groups of corpuscular texture,—soft, brittle, and incoherent. In the lungs, nothing resembling the adult pleura can be dissected, even with the utmost care, from their surface; and the thinnest section that can be made, gives (with a microscopic power of 700,) a coherent cellular texture, mingled with the isolated cells of an incoherent texture. The skin, both epidermis and cutis, viewed with a power of eighty diameters, exhibits a great number of *small dots* or granulations, and so likewise does the pericardium and the other (will-be) fibrous membranes. These granulations, when more highly magnified (700,) are found to be groups of coherent cellular texture, and the whole texture exhibits the same character. The young hair upon the head is very clearly a coherent cellular texture; the heart is a mass of elongated coherent cells; and it is only in the pericardium and other analogous strong membranes that waved fibres have yet appeared. The muscular fibrillæ are more advanced, and have their transverse markings; but nothing resembling nerve-fibres (properly so called,) can be detected, though cells with long projecting tubes, filled with a molecular matter, may be seen mingled with others, especially in the embryo texture of the spinal cord. In the bones of the cranium, the nascent osseous cylinders exhibit small, bony, or hard, cell-like particles, dispersed in a semi-transparent matrix, surrounded and enveloped on all sides in a very vascular fibro-cellular texture.

In the fœtus at birth, the soft corpuscular textures have assumed nearly their permanent characteristics; but this is far from being the case either with the fibrous, cartilaginous, or osseous textures, corpuscles or cells being still the most abundant elements in the fibrous textures, and largely mingled with the young fibres of the walls of the blood-vessels.

During infancy and youth all the later-formed textures are undergoing different phases of metamorphosis, until the adult period or permanent form is established. At the adult period the permanent textural form of the grey portion of the brain, of the liver, the intestinal villa, and the plexus choroides, &c., is *corpuscular*,—a soft, brittle, tender, and incoherent cellular texture. The parenchyma of the lungs is *coherent cellular*. The areolar textures, the dura mater, pia mater, pericardium, &c., *fibrous*; and, without making special reference to nerve-tubes, and muscular fibrillæ, there are also *fibro-cartilaginous, cartilaginous, and osseous textures*.* But, as all these textures were at first soft, brittle, incoherent, and corpuscular, the permanent form of some textures; then coherent-cellular, the permanent form of other textures; then fibrous, fibro-cellular, and cartilaginous, the permanent forms of others; and then osseous; so therefore it is concluded, that *the law of the metamorphosis in the human structure is from soft, semi-fluid, incoherent, corpuscular textures, to the coherent cellular; from these to fibrous, fibro-cellular, and cartilaginous; and lastly to bone.*

I am not aware that there is any difference of opinion among physiologists as to the general order in which the textures of the human structure appear, and I presume they are ready to admit that soft and but slightly-coherent cellular or corpuscular groups, precede the coherent cellular textures; that the cellular precede the fibrous and cartilaginous, and the cartilaginous precede bone. They are at least agreed upon the analogous fact in vegetable structure, "cells containing a viscous colourless mass mixed with granules everywhere," as Mohl observes "preceding the first solid formations."

In the human embryo then, the primary metamorphoses, out of which the future textures arise, take place in groups of corpuscular texture, before any circulating blood, or any blood-vessels can be detected; and the singular variety of the metamorphoses, even in a single organ, may be judged of from the structures of the eye. At this early period, it is by investigations with the microscope in the midst of these corpuscular groups, that the primary changes must be sought; but when blood-vessels or rather blood-channels are visible, and there is blood, a cellular or corpuscular fluid circulating through them, it is then along the inner margins of their walls that the nature of the subsequent metamorphoses,—those which establish the form and quality of the adult organs,—must be looked for.

The growth of the textures of the human embryo prior to the circulation of a current of blood-cells, is

* These are the broad distinguishing types of the textures, but there are many of a mixed character; the pleura is fibro-cellular, and the mucous texture of the air tubes is fibro-corpuscular.

in every respect analogous to the growth of the vegetable embryo prior to the formation of a green leafy parenchyma. And, as in the human structure, the blood current is essential to continued growth and future textures, so likewise in the vegetable structure, in the leafy parenchyma, and moreover, as vegetable structures are disposed to revert to a leafy parenchyma, so an analogous disposition will be shown to exist in animal textures.

IV. Structure of Blood-vessels.

The anatomical or structural elements of the *adult* blood-vessels, as long as their course lies embedded in a fibro-cellular or areolar texture, and whilst merely transmitting the current of the blood, although varying a little in different places, still uniformly consist of sundry layers of fibrous and fibro-cellular textures, the fibres in some of the layers being enlarged longitudinally, parallel with the course of the vessel, others circularly, passing around the vessel. The fibres are thick and strong, especially the outer layers, in proportion to the size of the vessel, or of the column of blood it conveys; and they inclose in their interstices, and are firmly united with, the nuclei of cells, and with a vast amount of granular and molecular matter, sometimes mingled with globules of oil or fat. In the very small branches of the blood-vessels, those which are on the point of leaving the fibro-cellular texture interposed between the lobular subdivisions of the various organs, and which are therefore approaching the scene of the nutritive function, the vascular walls or coats of the vessels are less fibrous; and it is evident from a careful examination, that they more and more partake of forms that are identical with those which constitute t he parenchyma or special texture they supply; until at length in the true nutrient or capillary channels it appears to be impossible to discriminate (certainly it is impossible to observe any *practical* distinction,) between the elements of the parenchyma and the walls of the vessels. Two textures easily examined, may be instanced in illustration:—In the pia mater the walls of the vessels are fibrous,—a transparent *fibrous* parenchyma or membrane; in the *plexus choroides* they are *corpuscular*,—a *corpuscular* parenchyma.*

But, as all the various textures, from the beginning in the embryo up to the period of birth, and from birth to puberty, are gradually ascending to their permanent forms, some reaching it soon, others later, so therefore the elements of the walls of the blood-vessels, and particularly those of the nutrient vessels, vary not only in the different organs, but in the same organ, *pari passu*, with the morphological evolution,—that is to say, in other words, they vary with the age of the organism, differing in the same place in the infant from the embryo; in the child from the infant; and in the adult from the child.

V. Structure of the Lungs.

The air-cells of the lungs are not indiscriminately thrown together in the interior of the organ; on the contrary, they are symmetrical with the branches of the air-tube, and collected or associated in numerous small communities or groups, each group forming what is termed a lobule; many lobules grouped together form a lobe, and five lobes form the two organs called the lungs. A pulmonary lobule is a perfect respiratory organ in itself, the whole lung being but a series of reduplications of the same structure—an aggregate of lobules. At one of the corners or angles of a lobule, a division of the air-tube, and an arterial blood-vessel enter into its interior, and at the same place a vein comes out, and by these three cylindrical structures the lobule is connected with its fellows. The membrane which forms the walls of the air-cells, constitutes the *parenchyma* or proper texture of the lungs, and the capillary vessels so densely distributed upon it have no other coats or boundaries than those furnished by this parenchymatous texture. The practical point to be insisted on, with a view to the correct understanding of the pathology and diseases of the lung, is that involving the relation of the walls of the air-cells to the extremities of the air-tube on the one hand, and to the blood-vessels on the other.

The air-tubes and blood-vessels before entering into the interior of the lobules, run in the spaces between them, and here, cushioned as it were upon an areolar texture, they have severally their own distinctive elements and structures; but within the lobules, after sundry subdivisions, they all terminate in, and their textures become continuous with, the walls of the air-cells,—that is to say, with the parenchymatous texture; and here it is impossible, even with the microscope, to discriminate between the elements continuous with, or prolonged from, the coats of the blood-vessels and those continuous with, or prolonged from, the air-tubes, —that is to say, in other words, the outer surface of the thin transparent wall of every air-cell is in close relation with the interior of the blood-vessels, and its inner surface is as closely related to the air-tubes.

The parenchyma of the lung is usually described by anatomical writers as a mucous texture,—that is, a secreting texture, but it has none of the anatomical characters of a mucous texture, its perfect transparency and elasticity resemble much more the characters of a

* The increasing importance of the elements of the walls of blood-vessels, as the vessels diminish in size, is indicated by the fact, which may be demonstrated in the vessels of a transparent texture, that the thickness of the wall is, as a general rule, *inversely proportional* to the diameter of the column of blood it conveys. In a large vessel, 1-100th of an inch, the thickness of the coat visible on each side as viewed through the microscope (70),) is not more than one third or one fourth the diameter of the column of blood; whereas in a small vessel 1-500th or 1-1000th of an inch, the reverse proportions are frequently seen; the thickness of the wall of the vessel being three or four times greater than the diameter of the blood-stream. Hence there is no difficulty in clearly seeing the stages of nutrition hereafter pointed out.

fibrous or serous texture; moreover, it is well-known that its capillaries have a special function, and no analogy whatever exists between them and the capillaries of a secreting texture. In the adult lung the parenchyma is *coherent cellular;* the areolar texture interposed betwen the lobules is *fibrous* and *fibro-cellular;* the pleura which covers the whole lung, and lines the interior of the cavity of the chest, is both *cellular* and *fibrous*,—cellular on its smooth free surface, and fibrous beneath. The mucous texture of the interior of the air-tube is *fibro-corpuscular*,—that is, composed of fibres intermingled with incoherent cells, and the blood is a *corpuscular fluid*, flowing in streams over the walls of the coherent cellular parenchyma. But in the embryo all pulmonary textures are composed of soft, and but slightly cohering cells; in the fœtus they are partly corpuscular, and partly coherent-cellular; and during infancy and youth the walls of all the nutrient vessels, even of those which have become fibrous, are largely charged with incoherent corpuscles or cells. Hence then, the morphology of the textures of the lung is *corpuscular*, *cellular*, and *fibrous;* and there is nothing, except in the larger branches of the air-tube, of a cartilaginous or osseous texture.

VI. Physiological Analysis of the Corpuscular, Cellular, and Fibrous Textures.

Keeping in view the distinctions insisted on between the *corpuscular* and the *cellular* textures, it is evident that the corpuscular are the secreting textures, and the cellular non-secreting ones,—that is to say, the cells or corpuscles of the secreting textures, with their thin walls and elaborated contents, are temporary and evanescent elements; while the cells of the coherent-cellular textures, with their strong elastic and transparent walls, are comparatively durable and permanent; and as the rapidity of the changes and displacements which the elements of a structure undergo, is in a direct ratio with their importance in the functions of nutrition, secretion, and life, so therefore the cells or corpuscles of the corpuscular textures are more active or energetic than the cells of the cellular.

Again contrasting the corpuscular with the fibrous textures, the latter perform the comparatively mechanical offices of separating, investing, and limiting in bulk, the different groups of the various corpuscular and cellular textures, engaged in the more active functions of life, transmitting the larger columns of blood to and from them. These functional distinctions are indicated by the anatomical fibrous element, and by the species of vascularity observable in the texture. The corpuscular or secreting textures are everywhere traversed by multitudes of nutrient vessels, specially disposed in different organs; whereas the fibrous non-secreting ones, although in some instances extremely vascular, in consequence of having to transmit a multitude of small vessels, have yet comparatively few nutrient capillaries, and these variable and irregular in their disposition. The dura mater and pia mater are both fibrous membranes, surrounding, supporting, and protecting in bulk, the whole brain or central organ of the nervous system. The dura mater, as its name I suppose implies, is an exceedingly strong and coherent texture, transmitting immense columns or streams of blood to and from the brain, yet is itself scantily supplied with nutrient capillaries. But the arterial currents traversing the dura mater, and those still larger ones arising from other quarters, before they can be admitted into the soft corpuscular texture of the brain, must be divided and subdivided many times into the smallest possible streams, and the force of the heart's action subdued by sinuous turns and windings. For these ministerial purposes the much more fine and delicate fibrous texture of the pia mater is interposed, which not only affords space and area for the subdivisions of the blood-current, thereby becoming extremely vascular, but slipping down between all the lobular subdivisions of the organ, (here termed convolutions,) it enters into the recesses, supporting and limiting and conveying vessels, through which the blood reaches and returns from all parts of the soft and tender parenchyma of the great organ of life and being. Lastly, the cellular parenchyma of the lung is not tender, opaque, and brittle, like the corpuscular parenchyma of the liver, but is on the contrary exceedingly coherent, elastic, and transparent, and these anatomical characters indicating, as before observed, that the parenchyma of the lung is not a place of active nutrition or cell-elaboration,—not a secreting texture; and although eminently vascular, more so, perhaps, than any other texture of the body, still the vascularity is analogous to that of the pia mater, a ministerial and not a nutritive vascularity, the analogies of the texture being altogether with the fibrous non-secreting, and not with the corpuscular and secreting textures. This corresponds with facts; the only outlet and inlet to the lungs is by the windpipe; and if the air-cells, which have been computed to number 1.744.000.000 in each lung, or if an expanse of membrane equal in area to 1500 square feet, were a secreting membrane in the ordinary and proper acceptation of the term, persons would be always swallowing, or spitting, or coughing, which we know in health is not the case. The fine transpararent cellular texture of the pulmonary parenchyma allows the finer and vapourous elements of the blood to transude its walls, but it does not, I conceive, in the proper sense of the word, give rise to a secretion.

(To be continued.)

OBSERVATIONS ON SECRET POISONS.

By H. S. Belcombe, M.D., Senior Physician to the County Hospital, and Physician to the Retreat, York.

Under the term 'Secret Poisons,' are to be understood all poisons which can be administered imperceptibly, and which gradually shorten life like a lingering disease. They appear to have been known from very ancient times, and accounts of their use have been handed down to us with much apparent authenticity from both Greek and Roman history. Modern times have also the credit of far exceeding in criminality and horror the ancient poisoners.

Theophrastus speaks of a poison which could be so managed as to have effect in two or three months, or at the end of one or two years, and remarks that the death the more lingering it was, became the more miserable. This poison, which was said to be prepared from aconite, was very much used at Rome about 200 years before the Christian era. As several persons of distinction died the same year at that period, and of the like distemper, upon an inquiry being made into the causes, a maid servant gave evidence against some ladies of the first families, who she said prepared and distributed poison, and above 150 were convicted and punished. As so many had learnt this destructive art, it could not be suppressed, and we find sufficient proofs in Roman history of a belief that it was continually preserved. Sejanus caused such a poison to be administered by an eunuch to Drusus, who gradually declined afterwards, as by a consumptive disorder, and at length died. Julia Agrippina being desirous of getting rid of Claudius, but not daring to dispatch him suddenly, and yet wishing not to leave him time to regulate the succession to the throne, made choice of a poison which should deprive him of his reason, and gradually consume him. This she caused to be prepared by the too celebrated Locusta, an expert poisoner, who had been condemned to death for her infamous actions, but saved to be employed as a state engine. The poison was given to the Emperor in a dish of *mushrooms*; but as on account of his irregular manner of living, it did not produce the desired effect, it was assisted by some of a stronger nature. She was also employed by Nero to despatch Britannicus, and when the first poison failed was compelled by blows and threats to prepare one more powerful, in the Emperor's presence; for this she was pardoned, liberally rewarded, and pupils allotted her, that the art might not be lost.

All these poisons were presumed to be prepared from plants, particularly aconite, hemlock, and poppy, or extracted from *animal substances*. With the stronger and now common mineral poisons the ancients do not appear to have been acquainted; their arsenic seems to have been what is called orpiment, and not that mineral preparation which in later times was in Italy and France brought to such tremendous perfection. Thus Horace, when mentioning the poisonous drugs used by Canidia, particularly dwells upon wild fig trees, funeral cypresses, eggs besmeared with the blood of a loathsome toad, and the herbs brought from Iolchos and Iberia, "Venenorum ferax."

No one has perhaps ever rendered a name more infamous than Toffana, a female who resided at Palermo, about the commencement of the eighteenth century, but who afterwards went to Naples. In Labat's travels through Italy much information is given illustrative of the history of Toffana. She distributed her poison in small glass phials, with this inscription, "Manna of St. Nicholas, of Barri," and ornamented with the image of the saint. A miraculous oil said to drop from the tomb of this saint, is shewn at Bari, and was much lauded and sought after on account of its reputed medical virtues. It was the best name she could give it, as its sanctity prevented its being examined too closely. She suffered at length the punishment due to her crimes; but Keysler says, when he was at Naples, many years after her death, the poison was still secretly prepared and much employed.

The most authentic description of the Aqua Toffana ascribes its properties to arsenic. The dose was said to be from four to six drops. It was colourless, transparent, tasteless, just like water.

Hahnemann gives a very lucid detail of the symptoms: "They are," says he, "a gradual sinking of the powers of life without any violent symptoms—a nameless feeling of illness—failure of the strength—slight feverishness—want of sleep—an aversion to food and drink, and all other enjoyments of life—lividity of the countenance—dropsy closes the scene, along with black miliary eruptions, and convulsions."

It was observed at Rome, under the government of Pope Alexander VII., that many young married women were left widows, and many husbands died when they became disagreeable to their wives. The vigilance of government being excited, suspicion fell upon a society of young married females, whose president appeared to be an old woman, who pretended to foretell future events, and who had often predicted very exactly many deaths. The whole society was by a stratagem arrested, and being put to the torture confessed their crimes. Le Bret, who has furnished a succint account of these things, says that the old woman, Spara, was a Sicilian, and acquired her knowledge from Toffana, at Palermo.

But the art of poisoning never excited more attention than it did in France about the year 1670. The Marchioness of Brinvilliers, a beautiful but infamous woman, having formed a licentious attachment with a young officer named Godea de St. Croix, by the influence of her father he was arrested and thrown into the Bastile. He there got acquainted with an Italian named Exili, who understood the art of poisoning, and from whom he learnt it. In this he afterwards

instructed the Marchioness, who was sunk by dissipation into a low condition, in order that she might employ it in bettering their circumstances. The whole of this terrible and curious history may be read in the Siécle of Louis XIV., (Voltaire.) Suffice it here to say, that St. Croix, when preparing his poison, was accustomed to wear a glass mask, but this happening to fall off, he was suffocated, and found dead in his laboratory. (On this I shall have to make a few remarks presently.) To such an extent was this system of poisoning carried, that a particular court, called the "Chambre de poison," or "Chambre ardente," was at length established; but it is a considerable question whether it was not made use of in a time of public panic or delusion for a political inquisition. It seems certain that only two women were discovered to be the principal perpetrators; and as these furnished a list of several of the first rank who had recourse to their services and sought the use of their remedies, there may be shrewd reason to suspect they furnished other modes of *secret poisoning*.

That mankind were, in an early stage of their existence, not only acquainted with the deadly effects of certain natural substances, when applied in minute quantities, and that they availed themselves of such knowledge for the accomplishment of the worst purposes, the records of history shew; but with respect to the secret modes in which such substances have been supposed capable of acting, the most extravagant credulity has been displayed. Such tales as have been reported of Parysatis poisoning Statira, by dividing a bird with a knife poisoned on one side;—of Livia poisoning the figs which her husband chose to gather himself;—of the kings and potentates who have been destroyed by poisoned boots, gloves, the fumes of a taper or a wassail bowl contaminated with matter extracted from a living toad, may well be consigned to the imagination of a wonder-seeking age, and, perhaps, were invented and related for some purpose of inducing fear or exciting suspicion. They certainly did continue for a long period to alarm mankind, and to perplex and baffle judicial investigation. Indeed, considering how frequently poisons were administered under the insidious forms of charms and incantations, and the difficulty of delivering the mind from superstition, we may, perhaps, less wonder at the strong expressions of the writers of those periods.

It appears to me difficult to believe that in a period of the history of Rome, renowned for the austerity of its virtue, and simplicity of its manners, a set of females should have applied themselves to the knowledge of poisons, and assembled to compose them. Livy himself does not appear to have believed it. He says there was a mortality caused by the temperature of the air, or by human malice, and the story seems as much a fable as the embassy to Æsculapius, and the voluntary embarking of the serpent.

All poets and romancers have taken secret poisons, charms, and incantations, under their most especial protection, and excellent use have they made of their materials. From Shakespeare's "juice of cursed Hebenon," down to Sir Walter Scott's admirable management of them, they have been employed for their various uses. In "Kenilworth" the Earl of Sussex is supposed to have been played upon, and the description given of him while labouring under the malady, accords exactly with the early symptoms I have quoted from Hahnemann; but a more powerful use is made in the novel of the "Fair Maid of Perth," where the death of Dr. Dwining is thus described.

"You see this trifling instrument, said the criminal, shewing a silver pen; by means of this I can escape the power even of the Black Douglas. Give him no ink nor paper, said the Baron hastily, he will draw a spell. Not so, please your Valiancy, said Dwining, with his usual chuckle, as he unscrewed the top of the pen, within which was a piece of sponge, no bigger than a pea. Now, mark this! said the prisoner, and drew it between his lips. The effect was instantaneous, he lay a dead corpse before them, the sneer still on his countenance."

Poisons long continued to be secret because there were no means known of detecting them. In the casket of St. Croix, were found sublimate, opium, regulus of antimony, vitriol, and a large quantity of poison ready prepared, the principal ingredients of which the physicians were not able to distinguish. Many have affirmed that sugar of lead was the principal ingredient, but the consequences of the poison do not seem to have indicated the use of that metal. From information obtained by the Abbe Gagliani, it was at one time generally believed to be opium and cantharides, and many presume that there have been different kinds of these Stygian waters; but Dr. Hahnemann's conjecture of their being arsenical neutral salts, seems most probable.

It has been said that St. Croix wore a glass mask during his manipulations. There is no doubt that the fumes of arsenic incautiously breathed may be of very dangerous tendency. Dr. Christison quotes many cases in his work on poisons. He quotes also an anecdote from Balthazar Timæus,—viz., that the famous Paracelsus, being one day put out of temper by an acquaintance, made him hold his nose over an alembic in which arsenic was subliming, and that the subject of this severe joke nearly lost his life in consequence. It would appear, also, that the poison acts with great rapidity when its fumes are respired. Poisoning through the lining membrane of the nose has also occurred. One case is quoted by Dr. Christison, where an arsenical lotion had been used by mistake. The individual was attacked with profuse discharge from the nostrils, and then with stupor, approaching to coma. Weakness of sight and of memory continued

after sensibility had returned, and he died two years afterwards, death having been preceded for some time by convulsions.

Beckman concludes one part of his history of secret poisons with these words:—"The more it is to be wished that preventives and antidotes were found out, and that the symptoms were ascertained; but this is hardly possible, as long as it is not known of what the poison properly consists." Much of what was thus wanted has in later times been supplied by the intelligence and industry of various persons, and perhaps splendid as are the discoveries of modern chemistry, nothing has aided more than the labours of Orfila upon this particular subject. It is only since toxicology began to assume an accurate and systematic form, that the physician can be truly said to be in possession of antidotes. It is to very recent times that he owes the discovery of the virtues of albumen as an antidote for corrosive sublimate and verdigris;—of bark for tartar emetic,—of the alkaline sulphates for sugar of lead,—of the alkaline and earthy chlorides for hepar sulphuris, (sulphuret of potass,)—of ammonia and chlorine for prussic acid;—also for ascertaining the superiority of magnesia and chalk over other antidotes for the mineral acids and oxalic acid; and the superiority of vinegar or oil for the mineral alkalis.

To those who have watched the rapid strides with which physiology has advanced within the last twenty years, it will at once be apparent, how powerful an instrument of research that science has found in the effects of poisons on the animal body. The observation of these effects has led in a peculiar manner to our present enlarged knowledge of the laws of absorption; it has greatly aided the experimentalist in ascertaining the respective part performed by the veins and the lymphatics in the discharge of this function; it has contributed to the discovery of the permeability of the living tissues, and the influence which this property has in producing many of the phenomena of absorption; it has helped to unfold the power exercised by absorption in the development of many vital actions, formerly ascribed to nervous operations. In short, it has been one of the principal guides by which Brodie, in this country, and Majendie, in France, have been directed in the progress of their brilliant discoveries; so that by a curious transition, what formerly was dreaded as the exterminator of life, and made available for acts of tyranny and deeds of infamous oppression, has now, by the guidance of a sound philosophy and active industry, become the means of investigating the laws of life, and of improving the art of preventing and curing disease.

If, however, they were employed in former days, as instruments of terror and distress, I grieve to say, that in these times, they can be, and have been, made available for the basest purposes of selfishness and dishonesty. I believe there is little doubt that race-horses have been drugged previously to running; morphine is said to be the article used; horses like it, and a small quantity is sufficient for the required purpose. A friend of mine told me, that having to ride a very unruly horse in a procession, a small quantity of opium was given it, and he went through his work with as much lazy indifference as if he had drawn a state carriage all the days of his life. It is from this source, perhaps, that whisperers and other horse-magi derive their power of taming.

I have mentioned that some of the ancient poisons were said to be extracted from animal matters, and it is certain that a poison can be generated from such substances.

I have thus run over cursorily the subject of secret poisons, with some reasons for my disbelief of their frequent use, arising from the superstition, the ignorance, and the want of scientific research belonging to those days. I will conclude with two observations, which may be considered as aphoristic deductions. At a time when a preparation of gold was strongly extolled for its various powers, particularly as a poison, Dr. Fordyce said he believed gold to be only a cordial for the pocket, but a poison for the mind. An ignorant physician, and even a learned but inattentive one, is often a poisoner; and a good cook is a certain slow poisoner, if temperance does not regulate our obedience to her mandates. Mr. Addison concludes one of his papers with the following observations—"That secret poisons were much in request, and sought to be employed in former days, I think there seems to be no doubt, and even excellent and well-judging writers appear to have believed in them. Whether in this time of greater knowledge they are not likely to be so employed, or whether the farther advance of science will lead to such a discovery of them as to baffle their use, I will not determinine, but one poison has been handed down from an early age of civil society, has been used through most conditions of life, and yet continues its operations; its only antidote is a more genuine love, and practical action of examining before believing,—I mean the poision of secret defamation."

CASES OF CYNANCHE STRIDULA, TREATED WITH THE SULPHATE OF COPPER.

By John Bryan, Esq., Surgeon to the Northampton Victoria Dispensary.

Case I.

John Penn's child, aged 18 months, living at Ecton, five miles from Northampton. October 26th, 1844, I was called in to this child, who was exceedingly robust, at ten in the evening, and found her with stridulous breathing and severe exacerbations, with spasm, threatening suffocation, and having all the characters of confirmed croup. She had been ill with hoarseness and

fever for three or four days previously. The following remedies were used:—

Hirudines iv. gutturi statim. R. Vin. Ipecac., dr. vj.; Oxym. Scillæ, dr. ij. M. Capt. dim. statim.

This remedy having produced vomiting, in about two hours the following medicine was commenced:—

R. Cupri Sulph., gr. xij.; Syr. Simpl., dr v.; Aq. Destillat., dr. vij. M. Capt. coch. min. omni vel bihor. To have a warm bath.

October 27th. There had been retching of thick mucus all the night without severe vomiting, and although the child was a good deal collapsed, the breathing was more free, but still there was some croaking sound. The bowels were freely opened. Warm bath repeated.

R. Cupri Sulph., gr. iv.; Syr. Tolut., Aquæ, utrq, oz. ss. M. Capt. coch. min. quartis horis.

28th. Breathing better; croaking sound nearly left.

Rept. Mist. Cupr. Sulph. R. Mist. Oleos., dr. v.; Syr. Tolut. dr. iij.; Vin. Ipecac., dr. ss. M. Capt. coch. min. iij., quartis horis.; at intervals with the Cupri Sulph. mixture, which was now given only twice or three times in the twenty-four hours, or whenever the phlegm seemed at all accumulating.

30th. Improving. Continue medicine.

31st. Improving.

November 3rd. Left off the Cupri Sulphas, which had only been given once or twice the last two or three days. From this time the child rapidly improved.

Remarks. The case at first appearance seemed hopeless, the croup being fully confirmed, the breathing of a suffocating character, and the child, independently of being robust, disinclined to take anything in any quantity, therefore the small quantity required of the medicine answered perfectly well.

Case II.

August 28, 1845. Mr. Wichens' little girl, aged 5, of Black Lion Hill, was taken ill on this day with catarrh or influenza, with slight hoarseness. The following remedies were prescribed:—

R. Pulv. Jacobi, gr. iij.; Hydr. Chlorid., gr. ij.; hora somni sumend. R. Liq. Ammon. Acet., Mist. Camph., Aquæ, sing. dr. x.; Spt. Æther. Nitr. dr. j.; Syr. Tolut., dr. iij.; Vin. Ipecac., Oxymel. Scillæ, utrq. dr. j.; Potas. Nitr., scr. j. M. Capt. cochl. ampl. iss., quartis horis.

August 29th. The breathing at the chest appearing tightened a blister was applied to that part.

Rept. Mistura. R. Pulv. Jacobi, gr. iss.; Calom. gr. $\frac{1}{3}$; Pulv. Ipecac., gr. $\frac{1}{3}$. Fiat pulvis cum sing. dos. mist. sumendus.

30th. The symptoms took on the form of croup, with stridulous breathing, and the croaking noise so characteristic of that complaint.

The powders were continued, and at the same time—R. Cupri Sulph., gr. xij.; Syr. Simpl., dr. v.; Aquæ Destillat., dr. vij. M. Capt. coch. min. ij., secunda quaque hora.

Gentle retching of mucus and phlegm was immediately induced after each dose with great relief to the breathing. The Tinct. Iodin. Comp. was applied freely to the throat over the situation of the larynx and trachea morning and evening.

Sept. 1st. Symptoms mitigated. Rept. Mist. Cupri Sulph. et Pulv.; et appl. Tinct. Iodini mane et vespere.

2nd. Improving. Rept. Med. et appl. Tinct. Iodini.

3rd. Improving. Repeat the medicine.

From this time the croaking sound in the breathing ceased, the Cupri Sulphas, therefore, which appeared to depress the powers considerably, was left off, and the mixture first prescribed given twice or thrice daily, the child all the time improving.

In this case, which was seen sooner than the first, the symptoms primarily indicated inflammation of the superior part of the chest, and were succeeded by inflammation of the larynx, which was speedily arrested by means of the Cupri Sulphas, with the application of Tinct. Iodini Comp. The child was of very weakly habit, and bleeding in any form appeared contraindicated.

Case III.

Mr. Wilson's child, aged 11 months, Cow Lane, Northampton. I was sent for late at night to this child, who had been ill for a few days with what the mother thought to be a common sore throat, with hoarseness, and she had noticed the croaking breathing the preceding night, so that the symptoms of croup, when I first saw him, were quite confirmed. He was very plethoric, but considerably depressed, and at first sight I thought the case hopeless, the spasms in breathing being so severe as to threaten suffocation.

Empl. Lyttæ sterno admov., et Tinct. Iodini Co. gutturi. R. Pulv. Jacobi, gr. iss.; Calomel, gr. j.; Pulv. Ipecac., gr. ss. Fiat pulv. tertia quaqua hora sumend. To have a warm bath. R. Cupri Sulph., gr. iv.; Syr. Tolut., Aquæ Destillat., sing., oz. ss. M. Capt. coch. min. tertiis horis.

Nov. 11th. 10 a.m. The symptoms were mitigated; retching of mucus and phlegm had quickly taken place after each dose of Cupri Sulphas, which relieved the breathing very much; and although there was considerable uneasiness from the application of the tincture of iodine and the blister, the child slept at intervals.

Cont. Mist. et Pulv. R. Pulv. Scam. Co., gr. iv.; Calomel, gr. j. statim; the bowels not having been relieved. This acted well in two hours.

Nov. 12th. Improving. Cont. Mist. et Pulv. The application of the tincture of iodine having taken considerable effect on the throat in producing vesication, was not repeated.

14th. Omitt. Cupri Sulph., et Pulv. cum Hydrarg. Chlorid. R. Pulv. Ipecac., gr. ss.; Pulv. Jacobi, gr. iss.; ter die sumend. R. Mist. Oleos., dr. ix.; Syr. Tolut, dr. ij.; Vin. Ipecac., Tinct. Camph. Co. utrq, dr. j. M. Capt. coch. med. ter die.

The symptoms now continued improving, with the exception of rather a hard cough, which ceased in two or three days.

Remarks.—Two of these cases were such, as I had, previous to trying the Cupri Sulphas, found intractable under the usual remedies, as leeches and blisters, with

ipecacuanha and squill emetics, and calomel and James's powder; and I have every reason to think that the Cupri Sulphas was the main remedy in effecting a speedy cure; but it seems to me to require constant watching, (as of course does also the complaint itself,) for there appears to be great collapse and paleness induced, with retching and usually purging of green stools. I first received the hint respecting this remedy from "Braithwaite's Retrospect," vol. 8, Art. 28, by Dr. Schwabe, and found the effects exactly the same as they are described in this article. I am disposed, however, also to attach some importance to the application of the tincture of iodine at the same time with the other remedies.

CASE OF POISONING BY EXTRACT OF BELLADONNA.

By John M. Banner, Esq., F.R.C.S., Senior Surgeon to the Northern Hospital, Liverpool.

T. N., aged nine, was affected, on the 27th of October, 1846, with mild scarlatina. The fever ran its course in about eight days. On the third day after the disappearance of the eruption, jaundice presented itself; the skin was highly tinged, the stools white, and the urine highly impregnated with bile. Although the eruption disappeared, it was not until the 27th of December that the process of desquamation was completed.

At the latter end of December (the 20th,) I was requested to see Master N., in consequence of the obstinacy of the jaundice, and considered it necessary to prescribe an ounce of extract of dandelion, to which was to be added two wine-glassfuls of water. Of this mixture he was ordered to take three tea-spoonfuls three times a day, and did so regularly until the 4th of January, when the pot which contained the extract was again sent to the druggist to be re-filled, and at night the water added as usual. For some reason unassigned, the night dose was not administered.

At eleven, a.m., of the 5th, the first dose of the mixture or fluid extract was given by the mother, at which time the boy was in good spirits, and in every respect much better; the secretion of bile was passing into the bowels; his appetite was improved, and we had good reason to consider him fast approaching to recovery. The mother left the patient in the charge of her maid for a few hours, having occasion to absent herself for that length of time. She had not been gone more than half an hour, when the servant states that she observed a strange and unnatural appearance about the boy, but did not feel any alarm, nor did she think it necessary to state the circumstance to the family until about half an hour later, (twelve o'clock,) when the boy began to talk very incoherently, and was extremely restless; the delirium became very high, but quickly passed off, when he became quiet, though constantly affected with twitchings in the arms. Not knowing what to do, and ascribing the state to exhaustion for the want of food, she administered a large quantity of hot tea, which caused *great sickness*.

When I saw the case at three o'clock, I was told that the boy had vomited twice after taking the tea, and had thrown from the stomach a large quantity, which had not been preserved. The patient appeared in a comatose state; the breathing was slow; the eyes fixed; the pupils dilated to the fullest extent, and insensible to the admission of light; the hands and feet were cold and moist; the pulse was remarkably quick and weak, and slightly intermittent. If roused the patient tried to seize hold of the person touching him, and would shout, and occasionally laugh loudly, and would throw out the arms as if striking at an object; he could not articulate, though he often muttered as if attempting to express something; there was twitching of the flexor muscles of the arms, particularly of the left; he frequently seized hold of the bed-clothes, and attempted to draw them up, as if to cover his head. I ordered wine and hot water to be given freely; warmth to be applied to the surface, and cold-spirit wash to the head, and a large enema of salt and gruel was administered. After this injection the patient became very restless, constantly trying to get up. Thinking it probable that he wanted to pass stool, we carried him to the chair, when he passed large evacuations, which would prove some degree of consciousness. There was great disinclination to swallow fluid; it required more than ordinary force to effect this object. After a considerable excitement, for a minute or two he would fall into a quiet state, scarcely moving; he would suddenly begin to throw about his arms, and strike them forcibly from him, and then seize the bed-clothes, and endeavour to draw them over his face and head. The arms occasionally twitched convulsively. I remained with the patient for a considerable time; the first impression was that he had taken some narcotic poison, contained either in an embrocation or cough mixture. We carefully examined the room, but could not find anything confirmatory of this.

Having explained to the family the great danger the child appeared to be in, and the difficulty I felt in assigning a cause for the sudden change in the case, Dr. Duncan was requested to meet me in consultation. We met at five o'clock, five hours after the first attack, at which time the symptoms continued as before related, with the exception that the surface generally was warmer. The wine and water had been *forced* into the mouth, and he had swallowed a considerable quantity, on various occasions

Dr. Duncan was equally at a loss with myself as to the cause of the symptoms; at first he was inclined to attribute them to the jaundice, or some intestinal irritation, but from the fact that the child had been so much better, and the bile beginning to pass into the bowel, at once did away with the first supposition. On questioning the mother (who had by this time returned home,) we for the first time learnt that fresh medicine had been procured on the previous night, and she did not at the time of mixing it think it quite the same as before On examining the extract we immediately considered it a wrong medicine, and pronounced it either belladonna or henbane. To make ourselves fully satisfied we visited the druggist who had furnished it, as well as the former pots of extract. He unhesitatingly acknowledged that he had sent the extract of belladonna, and for the moment did not appear aware of

the mistake. It appeared that he had to send out some of the extract of belladonna on the night in question, and the impression on his mind was, that the same extract was wanted for T. N., and thus the mistake arose. I mention this circumstance to prove that there is no mistake as to the extract of belladonna being given, nor of the quantity taken.

The mode of treatment was persevered in; the lotion to the head, the wine and water drink, and a powder containing rhubarb and calomel given, which acted freely. The evacuation was dark-coloured, and from the peculiar odour, we considered it to contain a considerable quantity of belladonna. The delirium continued during the night, little varying from the symptoms enumerated; the pulse became more intermitting and fuller, so that it was thought proper to discontinue the stimulants.

At four, a.m., of the 6th, sleep for the first time overcame the patient; he slept lightly for two hours, after which the delirium was less violent, the pulse more tranquil, though very intermittent. He again slept lightly until near nine, a.m., and appeared more conscious afterwards; the pupils were still fully dilated, and he did not appear to see objects clearly, for on taking his hand, he felt with the other hand at what touched him, and laughed very much; he had less disinclination to take fluid, and partook of a small quantity of gruel. During the whole delirium he showed, from his peculiar restlessness, that he either wished to pass water or stool, neither of which passed involuntarily. There was not the least appearance of eruption.

From this time the symptoms gradually disappeared, the pulse became more regular, the pupils gradually became less dilated, though very irregular in their action; it was not until the expiration of five days that they acted more regularly; at that time the right pupil remained more dilated than the left. He complained for several days of pain in the head and difficulty of vision; he could not see to read with ease for some time, indeed I may say, that it was ten days before he got from under the influence of the poison.

From the calculation made, we consider that at least thirty grains of the extract of belladonna was given. The belladonna did not appear to have any effect on the jaundice, beyond the fact of its deranging the system for some days.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF WILLIAM SANDS COX, ESQ.

By Peter Hinckes Bird, one of the Resident Medical Officers.

(*Continued from page* 69.)

Case XXII.

SCROFULOUS CARIES OF THE SPINE.

James Riley, aged 25, labourer, admitted March 25th, 1846, into the Queen's Hospital, Birmingham, under the care of Mr. Sands Cox. He states that rather more than two years ago he first felt a pain in his right side, which afterwards flew to the back; it was treated as a rheumatic pain; he gradually got worse, and eighteen months ago he was obliged to give up his occupation, as he got very weak, and was soon tired; the use of his legs was gradually impaired, and his back became weak, and he perceived that the backbone became prominent. He states that his legs have at times been drawn up at nights; his urine dribbled away, and he had not perfect control over defecation; has never had abscesses in the back nor in any other part of the body; had swelling of the submaxillary glands a short time since. He states that he contracted syphilis two years ago, for the cure of which he took mercury; has been under medical treatment for eighteen months; enjoyed good health previously,—that is to say, about two years ago.

He complains of dull aching pain in the dorsal region, and of slight tightness across the chest; he cannot stand or walk upright, but is much bent forward; his legs feel numbed and cold, and the sensibility is diminished; can retain his water perfectly; urine rather turbid, of natural quantity; pulse strong, 86; appetite good; has a slight cough; the muscles of his limbs are soft, flabby, and atrophied; has no pain in the arms. On examination of the back there was found projection of the spinous processes of the middle dorsal vertebræ; there is no abscess there, nor on any part of the body.

Ordered to be cupped on each side of the spine, and to remain in bed in the recumbent posture.

April 3rd. About the same; legs still numbed; appetite indifferent; bowels rather confined.

R. Quinœ Disulph., gr. xij.; Acid. Sulph. dil., dr. j.; Aquæ, Oss. M. Sumat oz. iss., ter die. Pil. Rhei Comp. ij. hora somni sumend.

6th. Better; bowels open; appetite improved.

20th. Much better; can walk in a more erect posture; appetite improved; cough quite gone; bowels regular; his urine presented this morning an iridescent pellicle; this he states he has noticed frequently before. On examination of a portion under the microscope, the beautiful prisms of the neutral phosphate, mixed with imperfectly-formed crystals of the neutral phosphate, and a few penniform crystals, with epithelium.

Contin. mist. tonica.

23rd. Bowels rather confined. To take Pil. Rhei Comp. ij., statim.

26th. Complains of pain in the back. To have an issue applied on each side of the diseased vertebræ.

29th. The sloughs have separated. To have the issue kept open by the daily insertion of peas.

May 6th. The issues have discharged freely; feels better; legs not so numbed; the pain has disappeared from the dorsal region, and occupies the lower part of the lumbar, extending from hip to hip; can walk much better.

14th. Can walk upright; pain in the hips not so severe; the urine, which was pale, and of a light amber colour, when examined under the microscope, presented

the simple stellæ of the neutral salt;* they appear adhering to a fine transparent hair.

22nd. His legs do not feel so numbed, the left is more so than the right; the pain in the hips is worse towards night; general health improved; issues discharge freely.

27th. Complains of dull aching pain in the hips, which is considerably increased towards night. Ordered to have the moxa applied in three places on each side at the upper part of the sacrum.

June 5th. The moxa afforded considerable relief to the pain. In other respects about the same.

27th. Pain in the hips better; more motion in the legs, which feel stronger; general health improved. Discharged relieved.

In this disease, of which the true cause is a morbid state of the spine, the actual curvature must be preceded by a disease of the parts, unaccompanied with any visible deformity, and cannot take place until the caries has made considerable progress, therefore the diagnosis in the early stage must be very obscure. The absence of abscesses may assist the diagnosis. More frequently the disease begins in the bones; when it does so, abscess commences early. According to Sir Benjamin Brodie, in many instances caries of the spine has its origin in an ulceration of the intervertebral cartilages, afterwards affecting the bodies of the contiguous vertebræ. The pain is most manifest when it affects the intervertebral substance. In this case it is most probable that the disease began in the intervertebral substance, as no suppuration took place, at least externally, and the pain was a constant symptom. Curvature in the spine, in the direction forwards, may arise from other causes, as a weak condition of the muscles, or a rickety affection of the bones; but in these cases the curvature is always gradual, and never angular, a circumstance by which it is distinguishable from the curvature produced by caries.

One common effect of scrofulous caries of the spine is the production of abscesses around the diseased bone; but it frequently happens that caries goes on to an immense extent, and even so as to demolish the bodies of certain vertebræ, without any abscess being produced. The venereal disease is said to be sometimes the cause of caries; but in this case it appears that the symptoms of caries were prior to those of syphilis. This disease is extremely frequent in children, (there are now two children in the Hospital affected with it,) but adults are by no means free from it.

In most cases of scrofulous caries of the spine, paralysis of the lower extremities, and even a more extensive paralysis, will come on sooner or later, and is more commonly met with in the more severe cases than in those less advanced; yet this is by no means universally the case, and it is really surprising to what an extent caries of the vertebræ may reach without the supervention of paralysis. Professor Cruveilhier† gives the particulars of a case of scrofulous disease of the vertebræ, in which no paraplegia existed, though no less than five of the bodies of the dorsal vertebræ had been totally annihilated, and the alteration in the shape of the vertebral column was such, that the upper half formed with the lower an extremely acute angle, which would have been still more acute, if it had not been prevented by the eleventh and fifth actually touching one another.

The appearance of the phosphates in the urine which is usually indicated by the iridescent pellicle, is of frequent occurrence in cases of diseased spine.

In the treatment of this case the two following indications were to be fulfilled—1st, to retain the spine in the most favourable position for anchylosis to take place; and, 2nd, to improve the state of the general health.

To fulfil the first indication, recumbency is necessary; for it will be obvious, that until anchylosis take place in a more correct position, there must always be a tendency towards a re-production of the deformity, should the patient attempt to walk or move about in the erect position, because then the weight of the head, chest, and upper extremities, would press upon the diseased portion of the spine, which would naturally give way as before, at the carious point.

To accomplish the second indication, the state of the digestive organs is to be strictly attended to, so that by a course of tonic medicines, assisted by mild purgatives, when required, the health may be so much improved, that a more healthy action of these parts may be re-established.

Anchylosis or bony union of the vertebræ is the only permanent cure when caries of these bones has taken place; but some believe that when there is caries of the vertebræ, anchylosis can only take place by the remaining portions of the bodies of the vertebræ being brought into absolute contact, under which circumstances the deformity must, of course, remain permanent, or, what is more probable, be increased. But the resources of nature are by no means so limited, for when caries of the spine occurs, the periosteum, the anterior common ligament, and the surrounding textures become thickened, so as to form a firm membrane or sac in front of the diseased bones, and thus prevent the pus which is formed being effused into the neighbouring parts; but should the sac be incomplete, or from perforation or other cause, allow the escape of the puriform matter, then lumbar, psoas, or other abscesses are formed, or the still worse consequences of effusion into the pleura or peritoneum follow, a circumstance which, however, rarely occurs.

If the progress of the caries cease, and the health improve, nature attempts, by the formation of new bone to repair the injury done, and to fill up the space produced by the greater or less absorption of the bodies of the vertebræ. If the remaining portions be allowed to continue in juxta position, union between them taking place, any improvement in the spinal deformity will be rendered impossible; but if the spine by suitable means be got straighter, and retained in that position, until a healthy osseous deposit take place in the diseased part, the resulting deformity will be much lessened, and sometimes rendered comparatively trifling, and the cure will be both complete and permanent.

PROVINCIAL
Medical & Surgical Journal.
WEDNESDAY, FEBRUARY 24, 1847.

We have lately received another of that valuable series of reports—the Quarterly Returns of Health and Mortality, issued by the Registrar General. It will be remembered that the return for the quarter ending September 30th, 1846, shewed a great increase of the mortality during the preceding three months, much of which was attributable to an epidemic of diarrhœa, cholera, and dysentery. From the return for the last quarter ending December 31st, 1846, we learn that, notwithstanding the decline of this epidemic, there is still a great increase in the mortality over the corresponding quarter of the preceding year, and over the calculated average. The excess of deaths in the one hundred and fifteen districts, included in these returns, the population of which in 1841, was 6,579,693, amounts to 7311 above the calculated number, to 12,943 above the corresponding quarter of 1845, the actual number of deaths being 52,905. It is obvious, therefore, that other causes of fatal disease must have been added to, or taken the place of, those in operation, during the previous quarter.

The early severe cold, setting in considerably before Christmas, seems to have had much effect, as bronchial, catarrhal, and pulmonary affections, were frequent, severe and fatal, especially amongst persons affected with heart-disease. Rheumatism is another disease to which a portion of the increased mortality in some districts is attributed, and diarrhœa still continued to prevail, in some of the northern districts especially. Other diseases which contributed to the mortality in certain districts, are measles, scarlatina, and typhus. In London, the deaths from cold and want were nearly doubled; and we are informed that "the sad condition, and the habits of the poor Irish emigrants, have no doubt contributed to deteriorate the health of Liverpool, Glasgow, and Bristol—the ports through which they enter—as well as to raise the mortality of Manchester, and other inland towns." It would seem therefore, that the mortality of the quarter is mainly attributable to the effects of cold, combined probably with scarcity, and the remaining influence of the epidemic constitution of the preceding quarter.

"It is well known," says the return, "that the decaying matters of marshes give rise to agues, dysenteries, and fevers; and it is proved satisfactorily by the facts collected under the Registration Act, that the excessive mortality from diseases of the zymotic and other classes, observed in towns, is occasioned by animal or vegetable poisons, with which the atmosphere is charged, in different degrees of concentration, depending on accumulated filth, crowding in dwellings and workshops, the closeness of courts, imperfect supplies of water, and the want of efficient sewers. The high temperature of the summer of 1846, in which the mean thermometer ranged from 0°2 to 7°7, above the average, during ten weeks out of thirteen, accelerated the decomposition, and increased the virulence of these effluvial poisons, as well as of the diseases which they promote. Once grown epidemic, the diseases continued to rage during the rest of the year. Thus the mortality of 1846 may be accounted for. If it took place in obedience to any cyclical law, or to a general cause acting simultaneously in Asia and Europe, the great fact remains, that the deaths were nearly twice as numerous in ill-constructed towns, where the poison is concentrated, as in the country, where it is diluted and destroyed by the fresh air."

The return proceeds to shew that the precise degree of influence which the various agencies of want of water, sewerage, or ventilation—crowding of the population—neglect of children—the practices of quackery—want of skilful medical advice—intra-mural interment—noxious emanations, &c., exercise in causing the high mortality of towns, is not easily determined; and then refers to the known improvement in the health of the navy, in consequence of the adoption of the enlightened views of our great navigator, Captain Cook. In ten months after leaving England, Anson lost 626 men out of 961 in three ships, from scurvy, dysentery, and putrid fever. In the year 1780, the Channel Fleet sent 11.732 sick to the Haslar Hospital, 1457 of whom had scurvy, 240 dysentery, and 5539 fever. In the year 1772, Cook sailed round the world, and returned in the space of three years, with the loss of only four men by accidents, and *one* by disease. After the adoption of his principles by the Admiralty, the health of the navy was raised to a satisfactory standard, and in Captain Parry's three voyages to the Polar region, only seven men died out of 334.

Captain Cook, continues the report, "did not wait till it had been settled how much of the sickness at sea was caused respectively by bad ships, dirty water, rotten provisions, the want of ventilation, and of lemon-juice. He procured, amidst great difficulties, *all* that he believed was requisite to the health of the men. The experiment, though not an *experimentum crucis*, as applied to any one cause, was successful. It did not solve a physiological

problem, but it saved the men's lives. If the general measures for the health of towns announced are proceeded with, they will no doubt be as successful as the similar measures introduced into the navy, and crowned in Cook by the award of the Royal Society in the last century."

Review.

Practical Remarks on Near Sight, Aged Sight, and Impaired Vision; with Observations upon the Use of Glasses, and on Artificial Light. By William White Cooper, F.R.C.S., Senior Surgeon to the North London Ophthalmic Institution, &c. &c. London, 1846. Post 8vo. pp. 216.

There are few subjects of greater interest to the comfort and enjoyment of a very numerous portion of the community, than those which Mr. Cooper has here selected for remark. Near sight is an extremely prevalent, and there is some reason to fear, an increasingly prevalent affection; what is termed aged sight or presbyopia is, more or less, the common lot of all who pass the middle term of life; and impaired vision of various degrees, the penalty which the artisan, the close student, and the man of science, are called upon to suffer, from a heedless use, or rather misuse, of the organs of sight, to which the love of knowledge, ambition, and too frequently also necessity, impels them.

Upon these several states Mr. Cooper's work contains much interesting and useful information, and sound practical directions, on the means proper to be employed in the alleviation of the original or natural defect, the remedies to be used when the sight has become impaired from want of due care, and on the adoption of certain precautions in the use of this first blessing of intellectual man, by which the powers of the eye may commonly be preserved intact, or at least in a state of efficiency, until the gradual failure of the entire organism gives impressive warning that mortality is the lot of all.

Neither is it the least recommendation of Mr. Cooper's Essay, that it is written in plain and intelligible language, fitted for the comprehension of the many who are so deeply interested, and who, yet in unconscious ignorance, are pursuing a course which, unless the warning note reaches them in time, may bring on a state and induce mischief beyond the power of human means to alleviate or control. Myopia, for instance, is an affection which by proper adjustment of the optical means at our command, admits of much alleviation. The vision of the near-sighted, by the use of glasses, from being confined and indistinct, becomes clear and defined. But the very perfection of the relief at first experienced too often leads to the increase of the mischief; the first sharpness of the newly acquired power of distinct distant vision, in certain cases (more especially when it is the power of adaptation of the eye to varying distances which is at fault,) after a time wears off; the glasses do not suit so well as they did at first; others of increased power are perhaps had recourse to, and with the same effect, until the original defect is greatly aggravated. On these several points Mr. Cooper's work contains information which the community at large, and even many professional men, are much in want of. The cause is pointed out, the remedy indicated, and the necessary precautions to prevent farther mischief duly enforced.

The observations on the use of glasses are extremely judicious, and, with those on the effects of artificial light, ought to be carefully considered by all who are in the habit of studying or working during the hours of night, or from whatever cause are compelled to have recourse to the aid of spectacles. We select the following case of the effects of the destructive use of the eye to which modern habits compel very many of the working part of the community:—

"Harriet Porter, a delicate-looking female, aged 19, applied at the North London Ophthalmic Institution, February 17th, 1846. She was apprenticed to a milliner, and had been for some time in the habit of working with her needle for ten hours each day. During the London season it was no uncommon thing, she stated, for her to work twelve, and even fourteen hours, daily. Her eyes, she said, felt strained and ached, after sewing for a short time, and she experienced great difficulty in working, especially at night, in consequence of a mist which came over her sight, and rendered all objects indistinct. This mist had been gradually increasing, and of late she had seldom been free from it. She was subject to headache, and frequently experienced a weight over the brows, with aching of the eyes, muscæ volitantes after the slightest exertion, and occasional flashes of light. The movements of the pupils were slow, the irides dull, and in the left eye I detected two minute adhesions of the margin of the pupil to the anterior capsule of the lens.

"Rest to the eyes, an alterative course of mercury, in connection with tonics, and continued counter-irritation to the forehead and temples, produced a highly beneficial effect; and the patient was discharged at the expiration of four months, greatly improved in health, and with her vision nearly perfectly restored."

This case needs no comment. It is unhappily but too frequent, and the records of our Ophthalmic Institutions could supply not only many such, but many more in which the over-tasked organs have become, from continued misuse and neglect, structurally and irremediably impaired. In conclusion, we would recommend a perusal of Mr. Cooper's work to all who are suffering from the defects of vision of which it

treats; to the consumer of midnight oil; to the philanthropist, and especially to the medical practitioner, as conveying sound information on subjects of such every-day occurrence, as notwithstanding their importance, from their very frequency often escape the attention to which they are so prominently entitled.

BIOGRAPHICAL NOTICE OF THE LATE MR. DODD.

[The loss which the Association has sustained by the decease of Mr. Dodd, of Ryde, (late of Chichester,) one of its warmest supporters and most distinguished members, was briefly announced last week. The subjoined notice by a gentleman who had opportunities of knowing his worth and estimating his talents, will, we doubt not, prove interesting to the Members of the Association.]

Died, at Ryde, Isle of Wight, Jan. 30th, having just entered the 45th year of his age, Ambrose Thomas Sturges Dodd, Esq., Fellow of the Royal College of Surgeons of England, and formerly surgeon to the Chichester Infirmary.

Mr. Dodd was the son of the late Rev. Moses Dodd, of Fordham, in Essex, and was born at Chichester, January 16, 1803. In his early days he displayed no particular talents beyond considerable intelligence, but he was of active mind and habits, and very early evinced that remarkable amiability of disposition which so strongly characterized his after life. While a boy he conceived a most restless desire for a sea life, and at the age of 13 years, was permitted to take a voyage to China, a circumstance he ever after reverted to with pleasure and amusement. Shortly after his return he decided on the profession in which he was destined to attain so high a reputation, and he commenced his medical studies with the late Mr. Lightford, of Oxford Street. While there he had a serious and dangerous illness; it was some form of thoracic inflammation, but, as was the case with his subsequent ailments, the exact nature of the attack was involved in some obscurity.*

He subsequently entered Guy's Hospital, where he distinguished himself as an intelligent and persevering student, and soon acquired such a standing that he was appointed Curator of the Museum, and Demonstrator of Anatomy. His connection with Guy's was between five and six years in duration.

In 1828, he was invited by Mr. Guy, a general practitioner at Chichester, to join him in his practice, to which he subsequently succeeded. Within a few months of his first coming to Chichester, he was appointed surgeon to the Infirmary of that place, a situation he held with much honour and success. He devoted himself to this Institution with so much zeal, and with so great satisfaction to the governors and subscribers, that on his eventually retiring from his office, he was presented at a public meeting convened for the purpose, with a piece of plate and a magnificent purse, in token of the high estimation his services had obtained, and of the respect in which he was held.

While at Chichester, he also took a warm interest in the Literary Institution of that city, in which he delivered several interesting and instructive lectures. He was also very active in the formation of the Institution Museum, particularly the ornithological department, which he collected and arranged.

Mr. Dodd suffered habitually in the spring and early summer from hay fever. This, for many years, continued to be increasingly severe, until in the summer of 1843, he became seriously out of health, suffering from coryza, with cough and general debility. While taking change of air and relaxation by the sea side, he was attacked with hæmoptysis. He had had a similar attack thirteen years previously, from which he recovered, and enjoyed subsequently tolerably robust health, but from the attack in 1843 his health declined. During the next two years, a voyage to America, and visits to Ryde and Clifton, with improved health, were alternated with returns to Chichester and practice, with relapses of his attacks of hæmoptysis, and increase of cough, accompanied with dyspnœa. In 1845 he determined on giving up his practice, and fixed himself temporarily at Ryde, where shortly after he was invited to join in an established practice. Some improvement in health stimulated him to his wonted energy, and in December, 1845, he called a public meeting for the purpose of establishing an Infirmary for the Isle of Wight. He himself accepted the duties of secretary to the undertaking, which soon prospered in his hands, and a large sum has been subscribed for the purpose. Although Mr. Dodd has not lived, even to see the foundation laid, he may yet be said to be the founder of this Institution, which may be looked upon as his last and posthumous work. It is a matter of deep regret in the Isle of Wight, that the yet embryo Hospital is deprived of his valuable aid.

In August last, while in better health than he had enjoyed for a considerable period, the hæmoptysis recurred. This attack proved more severe than any previous one, and from it he very slowly and only partially recovered. As soon as he was able he removed for a few weeks to Trent, in the neighbourhood of Tunbridge Wells, whence he returned in October, and resumed his practice. But this was now a labour ill-sustained, and during the last week in December he was compelled to keep his house. From this time his disease made rapid progress.

In the practice of his profession Mr. Dodd was always *au niveau* with the day, and he possessed a quick and ready discernment. As a surgeon, he was bold and enterprising, and evinced much tact and dexterity in operating. In his intercourse with his professional brethren he was always frank and honourable, and obtained a high rank in the good opinion of his compeers. He was an early member of the Provincial Medical and Surgical Association, to which he was much attached, and at the Anniversary Meeting held at Southampton, in the year 1840, the Retrospective

* It is probable that in this illness he contracted the adhesions mentioned in the account of the *post-mortem* examination.

Address on Surgery was read by him. He contributed frequently to the periodicals of the day, and furnished able articles to Dr. Todd's "Cyclopœdia of Anatomy and Physiology."

Mr. Dodd was married in 1832, and has left a widow and four children to deplore his loss. In his domestic relations he possessed very strong affections. He was much beloved by all who enjoyed his friendship, and very highly esteemed by a large circle of acquaintance. He bore his illness with patience and resignation, and met his death with all the fortitude inspired by a Christian's hopes.

Mr. Dodd was many times seen by some of our leading stethoscopists, and as these gentlemen had generally expressed great doubts as to the real nature of his case, he expressed a wish that his chest might be examined, which was accordingly done by his partner, Mr. Marriott, in conjunction with his friends Dr. Engledue, of Portsea, and Dr. Salter, of Ryde. The following is the result:—

Examination forty-nine hours after death. Whole body extremely attenuated. On opening the chest, only a small part of the left lung collapsed. The lungs generally were very much charged with carbonaceous matter, and with the exception of the posterior part of the right lung, studded with tubercles. The pleura pulmonalis and pleura costalis were nearly throughout adherent, mostly by old adhesions. Under the right clavicle the adhesion was densely fibrous, and the corresponding portion of the lung contained also much fibrous deposit, in addition to the tubercles which were more numerous on this side than on the left. The tubercles under both clavicles were in the state of softening, and there were several small cavities; the largest, on the right side, was about the size of a walnut. There was much gravitation in both lungs posteriorly, but principally in the right, where the greater portion of the posterior lobe was gorged with blood and was very friable. There was, however, in this situation neither fibrous nor any other deposit, except the infiltration of blood, nor hepatization or any adventitious growth, though it was in this situation, and this only that disease had been long suspected. The heart was pale and flabby but presented no appearance of disease.

General Retrospect.

PATHOLOGICAL CHEMISTRY.

COMPOSITION OF THE BLOOD IN PUERPERAL FEVER.

M. Hersent, who has taken this investigation as the subject of his inaugural thesis, terminates his researches with the following conclusions:—

1. The chief modification of the blood in severe puerperal fever consists in a great increase in the water; great diminution of the globules; and also in very considerable decrease of albumen.

2. These modifications are proportionate to the severity of the disease.

3. The proportion of fibrin is generally unaltered, and the blood is therefore not diffluent.

4. There are, nevertheless, some few cases in which the blood is more fluid than natural, in consequence of a loss of fibrin.

5. It is probable that the vitiation of the blood precedes the development of the disease.—*Recherches sur la Composition du Sang dans les Fièvres Puerperales* 1845.

COMPOSITION OF THE BLOOD IN CANCEROUS DISEASES.

Dr. Florian Heller has investigated the chemical and microscopical characters of the blood in a case of uterine cancer, and gives the following as the result of his enquiries:—

1. The blood-globules are of very variable size, some being smaller, others larger than natural; the smaller have generally a finely granulated outline, the larger are always smooth. As this condition is also observed in blood containing pus, it is not characteristic of the cancerous diathesis.

2. Cells perfectly analogous in form and size to those which are present in cancerous tumours, are also seen to exist in the blood.

3. The shining particles like fragments of gold are sometimes also met with. These particles vary much in aspect, being either yellowish or bluish, according as the field of the microscope is placed in respect to the light; they are in many cases perceptible to the naked eye, after coagulation of the blood, either in the clot itself, or floating on the surface of the serum.

4. The fibrin is constantly and absolutely augmented in all forms of cancer, whether the blood be obtained from the affected part or from the general system.

5. The albumen is either normal or below par.

6. The amount of solid matters generally is diminished. *Archiv. für Physiologie und Microscopie*, 1846.

PATHOLOGY.

ON THE CAUSES OF EXUDATION.

The author of an essay on this subject, Dr. John Hughes Bennett, observes, that the term exudation is applied not only to the act of passing out of the liquor sanguinis through the vascular walls, but also to the deposit in the tissues of the fibrinous portion of the blood. This confusion of the act and the result under the same term is, however, a failure in terminology, which is not confined to the point in question. The series of changes which precede exudation, are stated by Dr. Bennett, to be:—1. A narrowing of the capillary vessels, with consequent increased rapidity of circulation. 2. A subsequent dilatation of the same vessels, with retardation of the current. 3. Irregularity and oscillation of the current of blood. 4. The motion of the blood ceases, and the vessel appears fully distended. 5th and lastly, the liquor sanguinis, sometimes accompanied by the blood-corpuscles, is exuded through the capillary walls, which in the latter case are ruptured.

Dr. Bennett remarks, that this view of the changes preceding exudation, is perfectly in analogy with the effect of stimuli on other muscles,—namely, at first increased contraction, and afterwards paralysis, and is therefore sufficient to account for the initiatory portion of the process, the contraction and dilatation of the

vessels, with the increased and retarded flow of the blood, but it does not account for the stoppage of the blood, nor for the exudation.

The latter phenomena are generally attributed to obstruction, the blood-globules becoming merged together. This explanation, however, Dr. Bennett considers opposed to observation; for, 1st—the stoppage of blood does not, as is supposed, proceed from one point; and 2nd—the lymph space near the walls of the capillaries is still evident when the blood moves slowly, and only disappears at the moment it is arrested. He then examines the theory advanced by Dr. Williams and Mr. Addison, that the obstruction is due to the generation of a large number of colourless corpuscles which adhere to the sides of the vessel. He observes, that he has long doubted the truth of this assertion, and has recently performed experiments, the result of which convinces him of its fallacy. He thinks that the above named physiologists may have been deceived by the rendering distinct of the nuclei of the epidermic cells in the web of the frog's foot; which nuclei closely resemble the colourless blood-corpuscles. The explanation, the author observes, is also negatived by the recent investigations of Remak, who has noticed that the proportion of the colourless corpuscles is increased by abstraction of blood, and that the portions first drawn in inflammation contain very few. Dr. Bennett concludes, therefore, that the cause of the obstruction is yet to be discovered, unless we are content with the hypothesis of increased attraction between the blood and the parenchyma. In the last place, Dr. Bennett criticises the opinion of Dr. Robinson, that exudation is caused by lateral pressure exercised on the walls by the *vis a tergo*. He denies the trustworthiness of Dr. Robinson's experiment of tying the renal vein, and asks whether the changes in the capillaries are not due to direct mechanical irritation, (drawing the kidney out of the abdomen,) with exposure to the air. *Monthly Journal of Medical Science*, January, 1847.

CANCER OF THE BONES.

M. Nelaton, who has contributed materially to the elucidation of this disease of the osseous system, distinguishes four forms of cancer:—

1. In the first, nodules of cancerous matter are found in cavities in the interior of bones, which they exactly fill; the osseous tissue is in these points entirely destroyed. In the vicinity of this loss of substance, the bone does not appear to have undergone any alteration beyond a trifling increase of vascularity. As the disease progresses, the mass of cancerous matter increases in size, and at length forms a greater or less prominence on the external surface of the bone. In the long bones the cancerous matter frequently extends up the medullary cavity, a fact which is to be taken into account in performing amputation.

2. In the second form, the *osteo-sarcoma* of authors, the tissue of the bone has undergone profound alteration; it presents a voluminous swelling, the section of which exhibitis a number of irregular cellular spaces, filled with cancerous matter, in various degrees of softening. The bony tissue between these compartments appears to be rarified.

3. The third form is that in which cancerous matter is deposited in the interior of a bone, and in its development pushes the bony tissue outwards, which yields gradually, and becomes at length so thin as to form a mere shell, within which the cancerous matter is inclosed. This is the *spina ventosa* of authors.

4. In this form the cancer is developed external to the bone, and beneath the periosteum. But it is readily seen that the bone is altered; in fact it gives rise to a net-work of osseous matter, mingled with spiculæ, which projects into the cancerous deposit.—*Gazette des Hôpitaux*, Decembre, 1846.

PRACTICAL MEDICINE.

BLISTERS IN CONFLUENT SMALL-POX.

M. Piorry has for some time past derived great assistance from the use of blisters as a means of preventing the scarring of the face by the cicatrices of confluent small-pox. The pus, retained so long in contact with the tissues, and altered in character through the agency of the air which passes through the pustules by endomosis, causes extensive local destruction, and proves very injurious to the system when re absorbed. Various practitioners have proposed measures for obviating this inconvenience, as by cauterization of each pustule, (impossible in the confluent disease,) the opening them by scissors, needles, &c., &c. Experience, however, shews that over such means the blister has the advantage of—1st, opening at one time the whole of the pustules over which it is applied; 2nd, evacuating their entire contents, and preventing the consequences of the sojourn or re-sorption of pus; 3rd, counteracting the attendant erysipelas by diminishing the swelling; and, 4th, causing the scabs to fall off much sooner from the face than from other parts of the body. It has an advantage over mercurial plasters in not risking the excitement of salivation, the extent of evil which results from its use being a slight ischuria. The various plasters applied as abortives in this disease have been reproached with exerting a repellant action, and directing the morbid action upon the brain and its membranes. A blister, on the contrary, rather acts as a derivative.—*Medico-Chirurgical Review*, Jan., 1847, from the *Gazette des Hôpitaux*, No. 101.

ALUM IN PERTUSSIS.

Dr. Davies thus speaks of the employment of alum in pertussis:—After a long trial, I am disposed to attach more importance to alum, as a remedy in hooping cough, than to any other form of tonic or anti-spasmodic. I have often been surprised at the speed with which it arrests the severe spasmodic fits of coughing; it seems equally applicable to all ages, and almost to all conditions of the patient. I was formerly in the habit of taking much pains to select a certain period of the illness for its administration, and of waiting until the cough had existed at least three weeks, taking care that the bowels were open, the patient free from fever, the air-passages perfectly moist, and the disorder free from complication of any bruit. A continued observation of the remedy, however, has induced me to be less cautious, and I am disposed to think, that a very large amount of collateral annoyances will

subside under its use. The fittest state for its administration will be a moist condition of the air-passages, and freedom from cerebral congestion; but an opposite condition would not preclude its use, should this state not have yielded to other remedies. It generally keeps the bowels in proper order, no aperient being required during its use. The dose for an infant is two grains three times daily; and to older children, four, five, and up to ten or twelve grains may be given, mixed with *Syrupus Rhœados* and water. It is seldom disliked.—*Underwood's Diseases of Infants*, last Edition, p. 432.

CHLORATE OF POTASS IN SALIVATION.

Mr. Alison states, that having had many opportunities of observing the beneficial effects of the internal use of the chlorate of potassa, ($KO.ClO_5$,) in the various forms of pure anæmia, in which the intolerance of mercury is notorious, he was led to believe that as these closely resemble in many particulars the state of system produced by the full action of mercury, the medicine might be equally beneficial in the latter, and that the result of numerous trials exceeded his expectations. He warns us, however, that certain precautions are necessary in the use of the chlorate, as if it be given in injudiciously large doses, or for too long a time, it is apt to give rise to inflammatory symptoms. He thinks that it and mercury are antagonistic in their action.—*Medical Gazette*, Nov., 1846.

NEW REMEDY FOR MERCURIAL SALIVATION.

An American physician, Dr. Robertson, of Harrodsburg, has discovered that one of the commonest plants of his district, the *Ambrosia trifida*, has more prompt remedial powers in cases of excessive ptyalism, than anything he had previously tried. The patients are described as being generally relieved in six or eight hours of the more urgent symptoms, and completely cured in two days. The preparation employed is an infusion of the green leaves used as a gargle. Dr. Robertson suggests that the plant may also be found useful in other profluviæ, as leucorrhœa. The plant is known under the popular term of horse-weed—horse-mint. Dr. Robertson was induced to try it from observing that it completely cured a horse affected with slabbering. The effect is simply local.—*American Journal of the Medical Sciences*, October, 1846.

BISMUTH IN DIARRHŒA.

Rayer uses the tris-nitrate of bismuth in the diarrhœa of phthisical patients, and in that which occurs in typhus, with great success. It is also much employed in the diarrhœa of infancy.—*Gazette des Hôpitaux*, September, 1846.

Guérard recommends, under similar circumstances, injections of nitrate of silver, ten grains to the quart of water. In children the strength should be diminished. *Monthly Journal of Medical Science*, January, 1847.

CHENOPODIUM OLIDUM IN AMENORRHŒA, &c.

Mr. Houlton states that he has had frequent opportunites of watching the medicinal action of the Chenopodium olidum, and is perfectly convinced that it is a very safe and important remedy, in many cases in which the catamenial function is not duly performed. He employs the spontaneously evaporated extract in the form of pills, from five to ten grains, night and morning. In general, if the pills are taken regularly for a fortnight previously to the expected return, the beneficial effect of the medicine is manifested; should this not be the case, he repeats them in the same manner,—that is, for a fortnight previously to the expected change. He does not advise this medicine to be given in all cases in which the catamenial flux is suspended, for there are many cases in which attention to the general health will effect a cure, which it would be superfluous to detail. It is in those cases in which the uterus itself requires medicinal aid that the peculiar benefit of the chenopodium is shown.—*Medical Times*.

SURGERY.

TREATMENT OF PROTRUSION OF A WOUNDED INTESTINE.

When a wounded intestine protrudes, surgeons are by no means agreed as to what practice should be adopted. Among the older surgeons, Heister, Garengeot, De la Faye, Dionis, Sharp, Palfin, and others, inculcated returning the intestine without suture when the wound is small. Le Dran and B. Bell, on the contrary, recommend the smallest orifice through which the contents of the gut could escape to be sewed up. Among modern surgeons, Mr. Travers, though he concludes from experiments that very small wounds may with safety be returned, yet recommends the wound, however small, to be secured by suture, though M. Jobert represents him as attributing with Scarpa the most mischievous consequences to sutures, and utterly rejecting them. ("Traité des Malad. Chirurg. du Canal Intest., t. i., p. 73.") Mr. Lawrence dispenses with the suture in mere puncture, but recommends its employment if fæces could possibly escape through the aperture. Boyer considers the suture indispensible in wounds of the intestines exceeding four lines in length; Richerand rejects it in wounds not more than two or three lines long; Vidal de Cassis recommends its application when the wound is two lines long; and Jobert says we may safely return a wound three lines long, and, *á fortiori*, a puncture, even though a little fæces exude from it. Callisen, Richter, Marjolin, Begin, and Gibson, say that the suture should not be applied in small wounds of the intestines, but none of them specify what extent of wound may safely be left to nature; and Mr. Gibson, as if mistrusting his own precept, during an operation for strangulated hernia, successfully imitated Cooper and Lawrence, by tying a ligature circularly round a small aperture in the intestine. Mr. Syme speaks doubtfully on this matter, but thinks it prudent to make a point of suture when the wound exceeds a mere puncture. Finally, the suture is altogether rejected by some, as, for example, Scarpa; who, however, admits that a "timorous surgeon," afraid "to commit the whole to nature," might "with impunity, pass a ligature through the mesentery opposite the seat of the wound of the intestine,"—a proceeding, which others, with J. Bell, more timorous still, replace by stitching the wound of the gut to that of the parietes of the abdomen.—*Brit. and For. Med. Review*, Jan., 1847.

FORENSIC MEDICINE.

CLOSURE OF THE DUCTUS ARTERIOSUS.

The subjoined conclusions, by Professor Brenut, are quoted from a recent number of the *Medical Gazette* :—

1. If the child has lived only a *few seconds*, the aortal end of the duct appears contracted, and the vessel instead of being cylindrical throughout, acquires the form of a truncated cone.

2. If the child has lived for *several hours*, or a *whole day*, the duct becomes again cylindrical, although shortened and contracted in diameter. The size is about that of a goose-quill; it is therefore smaller than its root, and about as large as either of the two branches of the pulmonary artery, which have, in the meantime, become increased in size.

3. If the child has lived for *several days*, or a *whole week*, the duct contracts to a diameter of a few lines, about equal to a crow-quill; while the two branches of the pulmonary artery are equal in size to a goose's quill.

4. The duct is met with perfectly closed and quite impervious, at a much later period—*i.e.*, after the lapse of a very uncertain number of weeks, or even months.

Among the exceptional conditions, Brennt remarks that the contraction may be first observed at the cardiac instead of the aortal end. In one instance of a still-born child which was resuscitated, and breathed freely for a short time, and in which the thymus gland was absent, the duct was found of the size of a crow-quill, as in children which have lived for several days. He also states, on the authority of Joseph Schallgruhu, that the duct is sometimes entirely absent.

NEW METHOD OF DISTINGUISHING ARSENICAL STAINS FROM THOSE OF ANTIMONY.

M. Cottereau proposes a new proceeding for the above purpose, which consists in submitting the stain to the action of the vapour of phosphorus. The phosphorus is divided into small fragments, and placed on a plate, upon which the porcelain containing the stain is reversed. The experiment is conducted at the ordinary temperature. Spots produced by the arsenic disappear after a few hours, while those of antimony remain from twelve to fourteen days. These also disappear at length, but re-appear as the red sulphuret of antimony, by the exposure to vapour from a solution of hydro-sulphuric acid. Arsenical spots thus treated re-appear with the characteristic yellow of the sulphuret of arsenic.—*Gazette Médicale*, No. 37, 1846.

OPERATION FOR SCIRRHUS OF THE LEFT BREAST PERFORMED DURING THE INHALATION OF SULPHURIC ÆTHER.

By W. Philpot Brookes, M.D., M.R.C.S., Surgeon to the General Hospital and Dispensary, Cheltenham.

Having occasion to perform the operation of extirpation of the left breast for a scirrhous tumour, but in which the glands of the axilla had not become diseased, I gladly availed myself of this the first opportunity I have had of trying the effect of the inhalation of æther, and its being the first time it has been used in this town for any capital surgical operation, (although Mr. Tibbs, the dentist, had succeeded with it for the extraction of stumps of teeth,) I invited the following members of the profession to be present:—Dr. T. Smith, Mr. Eves, (one of the surgeons to the Hospital,) Mr. Dalton, Mr. Ocrell, Mr. Fagan, Mr. Tibbs, surgeon-dentist, Mr. Gregory, and Mr. Peart.

The great importance of this invention as regards operative surgery, renders it necessary that surgeons should make known all the cases that come under their observation, and on that account I have given the full notes of this one.

The inhalation of the sulphuric æther was kindly managed for me by Dr. T. Smith, (one of the physicians to the Hospital and Dispensary here,) who administered it with a simple gum elastic tube, with an ivory-mouth pipe attached to a damp bladder, placing in it about two ounces of æther, and putting the bladder in warm water. The æther used was Howard's sulphuric, which had been washed and re-distilled by Mr. Smith, chemist, of this town. At first we had some trouble to persuade the patient to inhale properly, but after a short time, and becoming herself anxious to have the operation performed, she did so vigorously, and the æthereal effect was produced in about four minutes from that time. She fell back in bed, the arms dropped to her side, the pupils dilated, eyes turned up to the orbit, and sensibility apparently gone.

I commenced my operation, which was performed by two elliptical incisions of about four inches in length, extending fully round the nipple to the border of the axilla, dissecting out the disease; one small artery had to be tied. The operation occupied about two minutes.

After the lapse of six minutes the patient recovered her consciousness, and when asked if she had felt any pain, said, "None whatever,—you have not done the operation, you are only deceiving me," and we had some difficulty to persuade her to the contrary; in fact, she would not credit it until I gave her the breast to look at. Since the operation she has been questioned by several parties how she felt, and her answer is, "It was a pleasant sensation, no pain of any kind, and she could not now even believe it possible the disease was cut out with a knife."

The patient had not any bad symptoms from the æther either during its inhalation or afterwards. The pulse rose from 80 to 125; she complained shortly after of a little pain in the region of the heart, but this left her in a short time; one wine glass-full of brandy and water was given her after the effect of the æther had left, and at night the pulse was soft, 100; patient very tranquil; skin moist; complains of some difficulty in voiding the urine. A sedative draught was given her.

All the gentlemen present, whose names I have deemed it advisable to give, felt perfectly satisfied that the operation was performed without the slightest sensation of pain or uneasiness, and expressed themselves highly gratified with the result.

On reviewing the cases of operations already performed under the influence of æther, we cannot regard

the invention in any other light than as one of the greatest boons ever offered to operative surgery, in alleviating the greatest distress of mind and body which patients always suffer when they are told they must undergo a surgical operation, and it must now become the duty of every surgeon to watch well the progress of this remedy, and judge for himself whether or not it is not capable of being brought into very general use. I am only sorry the talented inventor should have clogged it with a patent, which I trust will never be allowed to stand; he deserves a far higher reward than that of turning it to a mere mercantile production.

I cannot close this article without publicly thanking Dr. Smith, for the trouble he has taken in trying the effect of æther on healthy subjects, preparatory to giving it this patient, and the judicious manner in which he administered it for me.

Albion House, Cheltenham,
January 28, 1847.

INHALATION OF THE VAPOUR OF ÆTHER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I can imagine your readers to be almost saturated with "*Æthereal vapour*," in consequence of so much public attention having been directed towards this powerful agent; nevertheless, should you consider the accompanying comments, emanating from one of the oldest members of the Provincial Medical and Surgical Association, in any manner worthy of notice, they are at your service.

I understand it is generally admitted, that the chief difficulty that has attended the process of inhalation, has been the violent spasms and cough that accompanied it; and in some cases the operation has been brought into disrepute by the cerebral disturbance produced. I witnessed two cases last week at the Royal Berkshire Hospital of tooth-extraction in young females, and in each case there were considerable paroxysms of coughing when under ætherization; indeed, so much so, as to render them almost unsuccessful. I had a tooth removed afterwards by the house-surgeon of the Institution, being entirely unconscious of the operation when under the influence of the vapour, administered by Hooper's apparatus. From what I have read and witnessed in reference to this subject, and more particularly from what I have experienced by inhalation, the effect of which was charming after the *first* stage of *coughing* and *suffocation* had disappeared, by no means to be considered trifling, and only to be explained by persons who *have* experienced it, I cannot but imagine the chief difficulty would be remedied, provided the operator has the means of adminstering the æther in the *smallest* proportion at the *onset*, either by regulating the stop-cock or valve, as may be most convenient, or in a diluted state, as has been recommended, to direct the patient to inhale for the first minute or so, as softly and gradually as possible, and above all, not to hurry the operation by the introduction of the vapour too rapidly; for, with regard to the success of it, quite as much depends upon the manner of inhaling, as it does upon the operator who administers it.

I remain, Sir,
Your obedient servant,
S. W. KIDGELL.

Pangbourn, Reading,
February 9, 1847.

AMPUTATION PERFORMED UNDER THE INFLUENCE OF ÆTHER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The cases in which the inhalation of the vapour of sulphuric æther has been successfully employed in the provinces, for the purpose of rendering patients insensible to the pain of surgical operations, are now so numerous that it seems almost superfluous to record another, especially as the instances in which this powerful agent fails to produce the desired effect, or is attended with unfavourable or dangerous symptoms, are more instructive to the profession, and therefore better entitled to a place in your columns. I am, however, induced to send you the following case, which you can either insert at length or shortly announce in your usual summary:—

Mr. Neate, master of the British School, at Corsham, a few years ago, met with a severe accident by machinery, and was obliged to have his left arm amputated, about the middle of the humerus. As the bone protruded an inch and a half, and was merely covered by very thin skin, the patient was desirous of having a less painful and a more sightly stump. He suffered a great deal of pain during and subsequent to the first amputation, and therefore was very anxious to try the effects of æther. Mr. Washbourne, of this place requested me to assist him in the administration of the vapour and the operation. A common inhaler was employed, some pieces of sponge being placed in the æther, and a small piece so as to prevent any of the fluid entering the breathing tube. Three minutes *perfect* inhalation were sufficient to produce intoxication; another minute (as the flap operation was performed) was of course only required to effect the removal of the parts necessary for the formation of a new stump.

There were several small arteries to be secured by ligature, and the veins bled more freely than usual, and consequently delayed the dressing of the stump, a circumstance which I mention because I see in a report of some experiments upon animals under æthereal influence, just presented to the Academy of Sciences at Paris, that æther produces congestion in the veins and capillary vessels; and this state we might naturally expect to follow a great and sudden diminution of arterial action, as indicated by the state of the pulse, &c.

The inhalation was repeated two or three times; the patient was quite ravenous for its continuance, and in

proof that his muscular powers were very little diminished, it required some little force to take the inhaler from him. He felt no pain nor subsequent inconvenience, although ætherealized for more than half an hour. He not only heard but was the first to reply to any remark made in the room, and at times with a degree of levity somewhat amusing.

This is the fourth day after the operation. The stump has been dressed; it is partly healed, and the patient highly pleased with the result.

I am, Sir,
Your obedient Servant,
G. W. DYKE.

Corsham, Wilts, February 16, 1847.

EMPLOYMENT OF MATICO IN MALIGNANT DYSENTERY, AND IN WOUNDS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I cannot resist the privilege allowed me by Dr. Hartle, of making known, as speedily as possible, the good effects of matico, so judiciously employed by him in cases of epidemic dysentery, accompanied with profuse intestinal hæmorrhage. As the communication is of importance, and has been so kindly transmitted to me, uncalled for and unexpectedly, I shall feel personally obliged, if you will afford it early insertion in our provincial periodical publication.

Will you allow me also to avail myself of this opportuuity of stating, that the previous day's post brought me "A correct and amended List of Bosquet's Medicinal *Hydroids*, or Concentrated and Chemical Solutions of the Organic Alkalis," in No. 32 of which is that of matico. The dose is only from one to two drachms, or eight times the strength of my form of decoction, a novel mode of exhibition, which may prove a valuable improvement, and convenient for those who may not have access to the dried article itself.

I am always, yours faithfully,
THOS. JEFFREYS.

Great George Square, Liverpool,
January 26, 1847.

Port of Spain, Trinidad, West Indies,
20th December, 1846.

My dear Sir,—My druggist, of London, kindly sent me some of the Piper angustifolium, (Matico,) accompanied by the third edition of your remarks on the efficacy of this Peruvian styptic. It fortunately arrived at this time that a most malignant dysentery was prevailing in this town. The disease was ushered in with pyrexia, and the most malignant concomitant symptoms of the malady, accompanied by profuse hæmorrhage from the bowels, with extreme relaxation of the sphincter ani. In some of the cases tenesmus was distressing, while in others there was no pain whatever; yet in all, the blood was constantly streaming from the rectum, while the anus was extensively dilated. The Spaniards, aborigines of this island, call this disease, where it assumes such a malignant type, with dilated anus, "bischeo;" and they solely depend, as a restorative, on the use of lime-juice, taken as lemonade, *ad libitum*, glysters of lime-juice and water, baths of the same, and the dilated anus is plugged with a lime, which is nicely peeled, then cut round from the core, inverted, and introduced into the rectum. No inconvenience, pain, or difficulty, attends the introduction of the lime, for the sphincter ani appears to have lost all sensibility and power of contracting; for as fast as one plug is ejected another is immediately introduced.

The first patient I had suffering under this malignant type, was a youth, seven years old, son of a merchant in this town. My preliminary treatment consisted in clearing out the primæ viæ with an infusion of radix ipecacuhanæ, and immediately after I commenced the lime-juice treatment, (until I could obtain my matico from the vessel,) which I persevered in until the fifth day, when, finding my little patient was losing ground, that the hæmorrhage was increasing, and that the dilation of the rectum was more alarming, I instantly commenced with an infusion of the matico, (one ounce to the pint of boiling rain-water,) and gave a tablespoonful every third hour, and a glyster of the same infusion one hour after he had taken each dose of the infusion. His recovery was rapid, and a few days after he became convalescent, he quitted this place with his parents, and arrived safely in England.

The next case I had was a child of eighteen months old. The symptoms were in all respects the same as I have already stated, with the difference of pain; the first patient had very little, and that without tenesmus; this infant suffered severely whenever he had the inclination to stool, yet nothing was passed but blood. In this case I began with the infusion of ipecacuhana; and as soon as the little patient had recovered from the effects of the vomiting, I commenced with the infusion of matico, in doses of one teaspoonful every second hour, and one ounce of the same infusion to be injected into the dilated anus, one hour after taking each dose. The change which took place in the malady in twelve hours was far beyond my most sanguine expectations; the sphincter ani had recovered its sensibility and contracting power, and the child is now in perfect health.

I have chosen to give the summary treatment of these two cases, because they were my first; and again, they were children; yet I must state, that in like manner I treated every case (with the matico,) of this malignant malady that came under my care; and it is with satisfaction that I report its proving successful in every instance.

Two cases of wounds came under my care:—

Mr. John Coune. This man received by accident, a severe wound from a large iron wheel falling, the edge of which divided the scalp on the lower and front part of the right parietal bone, dividing a branch of the temporal artery, which caused a profuse and alarming hæmorrhage The mouth of the vessel was so visible, that no trouble could attend taking it up, but it was too good a case to allow to pass without giving a trial to the matico, and accordingly I applied a piece

of a leaf to the mouth of the vessel, and pressed it closely for some time. On removing my finger I found the bleeding was arrested; I remained for some minutes before I dressed or bandaged it, no bleeding took place, and in nine days the wound was healed, and the man returned to his work as a blacksmith.

Mrs. Murser. This woman accidentally received a wound on the thick part of the thumb, two inches long. When she came to me the wound was bleeding most profusely from two small arteries, which I could very easily have taken up, but as I was anxious to give the matico another trial, I immediately applied a piece of leaf, which covered the mouths of both vessels, and by pressing the edges of the wound on the leaf for a few moments the hæmorrhage ceased. I then put a piece of adhesive plaster round the hand and wound, leaving the piece of matico in the wound. On the fourth day I opened it, when I found the piece of leaf detached and the wound uniting generally. On the ninth day it was completely healed; and now, three weeks since, it continues so, without any inconvenience.

I beg to assure you that I shall continue to avail myself of every opportunity of using the matico, and I shall have much pleasure in communicating my observations. Permit me to say that you are at liberty to make any use you please of these observations, and with every hope that they may prove useful,

I remain, my dear Sir,

Your most obedient servant,

ROBERT HARTLE, M.D., F.R.C.S.E.,

H. P. Deputy Inspector General of Army Hospitals.

To Thomas Jeffreys, Esq., M.D., &c.,
Liverpool.

ON SCORBUTUS.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

It seems generally admitted that true scurvy is now of rare occurrence,—that it is one of those diseases which the operation of an amended dietary, or of some other change in the general habits of the people of this country has happily nearly extirpated. That this may be mainly owing, as has been stated by some, to potatoes having become a staple article of food for many years seems not improbable; and if the reappearance of scurvy should unhappily be amongst the *mille mali* consequent upon the failure of the potato crop for the last two years, all the force of proof will be given to the opinion.

Be this as it may, I had not seen a case of scorbutus for the last twenty years, when about two months ago my friend Mr. Ince, surgeon to the County Gaol here, requested me to see with him three male prisoners then labouring under the disease in an aggravated form; extreme general debility, fœtor of the breath, teeth loose, turgidity and sponginess of the gums, livid subcutaneous spots and ecchymoses on the limbs and muscular contractions were among the symptoms. One of them, a man of dropsical habit, died; the other two recovered and are now quite well.

Nitrate of potash internally, and the chloride of calcium in solution externally, were evidently productive of benefit; but the beneficial effect of change of diet was demonstrated in a very striking manner. In consequence of the scarcity of potatoes, peas were ordered as a substitute in the prison rules, and under the use of the pea food the disease made its appearance. By a very proper regulation in the prison management the surgeon has the power of altering the diet, and Mr. Ince judiciously ordered bread instead of peas, with some porter also. This was immediately followed by improvement in the two cases, and after some time the peas food was resumed, when the symptoms returned, but again yielded to the amended diet.

These seem the only points of interest in the occurrence, and to enter into minute details of particulars would occupy your space and the attention of your readers uselessly.

I cannot, however, conclude without asking leave to express my concurrence in the decision come to by the Committee, to continue the Journal fortnightly. To those, who, like myself, feel a desire to submit a question, as it arises, to the judgment of a numerous and influential body of practitioners like the Provincial Association, the Journal affords the easiest, best, and pleasantest mode of making the communication.

I am, Sir,

Your obodient servant,

A. W. DAVIS.

Presteign, Jan. 20, 1847.

MANIPULATIONS OF A CORN-CURER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Having read in your valuable publication, for December 23rd, 1846, p. 615, a communication headed "Committal of a Corn-Curer for obtaining Money under False Pretences," I now take an opportunity of stating the result of the trial of the chiropodist, and forward to you, for the information of my professional brethren, a particular detail of the artist's mode of operation, and the result of it in the discovery of a nursery of corns, where the most eminent men in our profession appear never to have thought that they were ever grown.

Joseph Wolff, tried at the sessions for the county of Suffolk, held at Beccles, on the 4th instant, on a charge of having, in the borough of Southwold, in that county, on the first of December last, obtained from a gentlemen resident in that town, the sum of one pound by false pretences, represented in the calendar of prisoners as thirty-five years of age, a labourer of the city of Norwich, but who, by his hand bills, had represented himself as Dr. J. Wolff, chiropodist, patronized by a crowned head, and every grade of nobility and gentry, from the throne downwards, was acquitted by the jury on the ground, as it would appear, of insufficient evidence, arising, perhaps, out of the loss of materials, pretended to have been extracted as corns, and the difficulty of shewing that the whole sum

charged was a fraud, as what is usually called a corn had been operated upon, and the patient felt ease from it.

The theory of the chiropodist, as frequently stated, is, that corns are generated in considerable numbers in, and spring from, the bone immediately under what has never before been doubted to be a corn, and in order to the extraction of which, in the cases alluded to, and at which I was present, the following was the ceremony of operation:—Seating himself with his face towards the light, and taking care to object against any person placing himself in a situation distinctly to see the whole operation, the operator threw a handkerchief over his knee, upon which the foot of the patient was laid. The visible corn was then pressed somewhat unceremoniously, to give, it is presumed, the patient a sufficient idea of the pain occasioned by such things, and the value of the service rendered by the removal of them. The chiropodist then proceeded to pare the uppermost layer of the thickened cuticle of every corn upon the same foot, using a number of variously shaped scalpels. He then proceeded to loosen, by means of a set of instruments, like gum lancets of different shapes, and some of them much rounded, the entire natural corns, turned them up and on one side; then cut off the more callous part of each, leaving the under layer of the cuticle, of which he continued to form a sort of flap, which he subsequently made use of. With crooked scissors of various sizes, having clipped away all uneven surfaces from the different corns under operation, then with suitable solemnity the operator took from a round box a bottle of mysterious oil, somewhat resembling blood, which he represented as having the power to raise the corns. This oil was with abundant care rubbed over each toe operated upon, and into each excavation made in it until it foamed, and at this perhaps *critical period* of the operation, the operator *invariably* resorted to some manœuvre to attract the attention of any bystanders, and each flap before spoken of being carefully closed over the orifice, and the oil wiped from the outer part of the toes, the chiropodist then by means of an instrument, like a large silver tooth-pick, with great adroitness, disengaged what he called the corns, and brought them one by one to view, exclaiming—"See de corn." The object being thus made visible, the operator taking up a pair of long broad forceps, deeply grooved, and closing with a slide, proceeded to lay hold of it, and suiting the action to the *extremity of the case*, he affected to exercise the utmost judgment and care in the ceremony of extraction, which, having with apparent difficulty effected, the self-created corn was usually triumphantly exhibited, and its point applied to the back of the patient's hand, no doubt that its power to give pain might be felt. In conclusion, the flap before spoken of was trimmed off, and if there was any appearance of blood, the chiropodist applied small pieces of charpie, dipped in a yellowish brown astringent, and every toe operated upon was bound neatly up, and secured with adhesive plaster.

The Wolff corns, or the spiculæ designated by Dr. J. Wolff as corns, are horny, bristly, or bony substances, which may be manufactured, either of the parings of horses' hoofs, or the bones of fish; but I have great reason to believe they were manufactured from the parings of horses' hoofs. In length they are about one quarter of an inch, some jagged, some smooth, and some curved, and in size do not exceed that of a small pin. The members of our profession will have no difficulty in forming a correct opinion of his talent in practical imposition, which appears to have been carried nearly through the length and breadth, not only of our island, but into Ireland, to say nothing of the continent. In Ireland I have evidence of the extraction of eight pounds from the purse of a lady; and in my own immediate neighbourhood, of six pounds for twenty-five spiculæ. From London I have received various communications, and amongst them, of the extraction of fifteen guineas from two gentlemen residing in that fountain-head of medical and surgical knowledge, besides similar, and indeed greater impositions, practised elsewhere. The most gratifying communication, however, has been from Cheltenham, where it appears that the impostor for his mal-practises on the feet of his patients, was sent to exercise his own feet on the treadmill.

The object from first to last in the proceedings against Dr. J. Wolff has been to expose the absurdity of his theory, and the extent of his trickery, and the object of addressing to you this exposition of the mystery of his operations has been to shew the necessity of great caution, particularly in our profession, in certifying anything not well understood. In my own case I considered myself perfectly secure from imposition, not simply from the personal recommendation of Dr. Wolff by the gentleman whose house he had just left, but from a splendid book of certificates containing the autographs and seals of several noblemen, and printed testimonies from many members of high eminence in our profession, on which I could but rely as fully justifying a recommendation of the operator to my friends, by whom they were so grossly deceived, and the deception upon whom well warranted in my opinion the proceedings which I thought proper in justice to them to adopt.

ROBERT WAKE, M.D., M.R.C.S.

Southwold, Suffolk, January 18, 1847.

Medical Intelligence.

OPERATIONS PERFORMED UNDER THE INFLUENCE OF ÆTHER.

Operations continue to be successfully performed under the influence of æther at the Provincial Hospitals. Among them may be mentioned the removal of a scirrhous mamma, and of a portion of the middle finger, by Mr. Cotton, of Lynn; and a very severe operation on the foot with the most perfect success, at the Worcester Infirmary, by Mr. Carden; with others, by Dr. Brookes, of Cheltenham; Mr. J. H. Stallard, of Leicester; Dr. Barker, of Bedford, &c. &c.

MEDICAL APPOINTMENT.

Eusebius Arthur Lloyd, Esq., has been elected Surgeon to St. Bartholomew's Hospital, in the room of Mr. J. P. Vincent, resigned.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, February 4th:—William Philip Harrison, Sheffield; Edward Simpson, Swadlincote, Derbyshire; John Frederick Stevenson, Birkenhead.

Gentlemen admitted Licentiates, Thursday, February 11th:—William Cadge, Hoveton St. John, Norfolk; Richard Charles Skettle, Mapperton; John William Abell, Mitchell Dean; Henry Ashton Ramsbotham; William Weston, Ellaston, Staffordshire; Samuel Lawrence Gill.

OBITUARY.

Died, January 16th, at Nice, aged 43, M. Leon Mirza Labat Khan, Doctor of Medicine of the Faculty of Montpellier, Chief Physician to the Shah of Persia.

January 31st, aged 78, Lynch Conway Gent, Esq., Surgeon, Fenny Stratford, Bucks, in which town he had practised upwards of fifty years.

February 4th, aged 69, M. Dutrochet, a distinguished philosopher, well-known as the discoverer of the property of endosmosis.

Lately, M. Ranque, M.D., Chief Physician to the Hospital and Prisons, and Dean of the Faculty of Medicine of Orleans.

Lately, aged 73, M. le Baron Pasquier, Surgeon in Chief to the King of the French.

Lately, at Plymouth, aged 90, James Watt, Esq., Senior Surgeon of the Navy. Mr. Watt served as Assistant Surgeon and Surgeon, on board the *Ramilies* and other ships, in several naval engagements, under Keppel, Rodney, Saumarez, and Sir Richard Strachan.

MEDICAL & SURGICAL JOURNAL.

A COURSE OF LECTURES ON CLINICAL MEDICINE.

By W. R. Basham, M.D., Physician to the Westminster Hospital.

Lecture VII.

Fatal case of acute Bronchitis, preceded by pulmonary or chronic catarrh: History of the case, and post-mortem appearances.—Distinction between pulmonary catarrh and bronchitis.—Catarrhal affections of the pulmonary mucous membrane; their frequent tendency to recur.—Pathological state of the mucous membrane in acute catarrh.—Catarrhal irritation always extends from above downwards, from the larynx to the bronchi, never reversely from the bronchi upwards.—Microscopic characters of catarrhal secretion.—Pathological characters of acute bronchitis; stethoscopic signs; secretion.—Plastic exudation in the severest forms of bronchitis.—Heart-disease, and pulmonary catarrhal affections, tend mutually to aggravate each other.

Gentlemen,—At our last meeting I had occasion to explain to you the pathological conditions of broncho-pneumonia; and at that time I made allusion to another case in the same ward, of a patient suffering from symptoms of acute bronchitis, but which had supervened upon a chronic affection of the mucous membrane of the air-passages, and from which he had suffered for some time, amounting probably in its earlier stage to little more than pulmonary or chronic catarrh, a complaint but too often neglected, from its being usually at first unaccompanied by any great disturbance of the general health, but which is constantly prone to pass into very serious and fatal lesions of the pulmonary tissues.

A. B.———, aged 40, a German watchmaker, was admitted on January 6th. He was suffering from urgent and suffocative cough; distressing dyspnœa; face livid from venous turgescence; profuse sputa; has suffered from cough and dyspnœa during the last two months; the cough has occurred in paroxysms; the countenance is very anxious; features turgid; lips livid; eyes protruding and glazed; intellect torpid; there is also general anasarcous swelling of the surface of the body, trunk as well as extremities. The chest appeared well proportioned, was resonant throughout, but more so than natural in the mammary and lateral regions of both sides; the respiratory murmur was not audible; cooing and wheezing sounds present in every region, but more particularly in the interscapular space; mucous rhonchi of large bubbles also in each region; the heart's sounds were rythmical, but somewhat sharper than usual. The bowels had been relieved; tongue moist; pulse 108, small and compressible; sputa very profuse, frothy, and stained with blood; urine very high-coloured, and loaded with urates.

These symptoms were palpably indicative of an inflammatory condition of the whole extent of the bronchial mucous membrane, and from the existence of cough and dyspnœa for two months preceding, it was considered as an attack of acute bronchitis, supervening on pulmonary catarrh. The nature of this complication will be presently explained. It was obvious that the treatment must be conducted on the principle of relieving the congestion of the bronchial mucous membrane, and by medicinal agency preventing the further throwing off the products of inflammatory action. To this end he was cupped between the shoulders to eight ounces, a mode of relief to the congestion of the pulmonary organs, in general very efficient, and in most cases of this kind preferable to general blood-letting from the arm. A blister was applied to the anterior part of the chest, and he was ordered Hydrarg. Chloridi cum Opio, utrq., gr. j., sextis horis, and the Mistura Salina Ammoniata, quartis horis. This latter medicine was prescribed with the view of obviating any tendency to prostration and collapse, as well as at this stage to promote secretion from the bronchial passages, with free expectoration, which object is well obtained by saline draughts with ammonia in excess.

On the 7th, the day following, the report states that he was relieved much by the cupping, and for an hour or two breathed freely and comfortably, the lividity of the countenance subsiding, and the expression being less anxious. He, nevertheless, passed a very restless night, with much wandering and moaning; and on the examination at the daily visit, cooing and sibilant sounds were heard everywhere, with much expiratory wheezing, and mucous rhonchi of both large and small bubbles. The sputa were very plentiful, frothy, fluid, and sanguinolent; urine loaded with urates; the pulse was very small, soft, and compressible, 90. Later in the afternoon the lividity and congestion of the countenance again returned; the respirations 48, hurried, gasping, and laborious. A remarkable amount of venous congestion of the vessels of the scalp appeared, which was followed by a state of coma, and he died at 4 a.m.

Sectio cadaveris twenty-four hours after death. The body was œdematous over the entire surface; plentiful serous exudation from every tissue as the knife passed through the abdominal and thoracic parietes; a moderate amount of clear serum was present in the cavity of the abdomen. The lungs did not collapse on raising the sternum, but were attached by firm bands of tissue to the pleura costalis; no trace of recent plastic exudation could be detected; the lungs on their anterior surface, and particularly about the middle lobe, presented many emphysematous patches, one or two of the size of a filbert; the margins of the inferior lobes were also covered with emphysematous vesication; the posterior and inferior portions of the lungs were dense, with cadaveric infiltration, a plentiful sanguinolent serum (frothy,) exuding freely on a section being made. The mucous membrane of the bronchial tubes was turgid and swollen, of an intense dark, madder-red colour, and from them into the lesser series the colour passed into a purplish violet, and presented the appearance as of intense venous hyperæmia; the larger tubes were smeared over with a glutinous, tenacious, and very adhesive secretion, and many of the smaller tubes seemed quite blocked up with this gelatinous mucus. It was of a faint fawn-colour, and at no point could any appearance of yellow muco-purulent secretion be detected. Under the microscope this exudation had a fibrinous appearance, and exhibited many granular cells; none could be found that presented any of the characters of pus-globules. The heart was much enlarged, but uniformly so; no valvular thickening nor opacity; the walls were relatively thin in respect to the increased capacity of the auricles and ventricles; it weighed twenty ounces. The liver was not unhealthy in appearance, presented indications of a large amount of portal congestion, and weighed forty-eight ounces; the kidneys were free from any morbid appearance, the right weighed six ounces, and the left five and a half. The brain was not examined.

This case explains to us many of the pathological conditions of pulmonary catarrh, bronchitis, and emphysema. Pulmonary catarrh is one of the most frequent and commonest precursors of the severer and more fatal forms of bronchitis. Pathologically it can be said to differ from bronchitis only in the amount and intensity of the preceding hyperæmia; the usual products of inflammatory action, pus, and plastic exudations, being the result of the more intense morbid action; while in the milder affection, epithelial cells, granular corpuscles, and fluid mucus, are generated and expectorated to a greater or less extent. To the latter the term catarrh, or pulmonary catarrh, is usually applied; while, to express the former, we employ the word bronchitis. I propose to examine the pathological conditions of these affections somewhat minutely, as the case before us presents me with a favourable opportunity practically to illustrate these morbid conditions.

Catarrhal affections of the mucous membrane of the trachea and larger bronchial tubes may be reckoned among the most frequent derangements of the system, and except in rare cases, are from the first treated as trivial, and receive no very great attention on the part of the patient; nevertheless, a condition apparently so trifling, and accompanied by no great amount of physical disturbance, may, by its tendency to recur again and again, under favourable circumstances, and often does, lead to serious mischief, and ultimately even to fatal consequences. According to the best authorities, in the earliest stage of acute catarrhal affection, distinct portions of the bronchial mucous membrane exhibit patches of a fine rose-red injection, which are not circumscribed by a definite boundary, but gradually become diffused, and insensibly lost in the surrounding pale tissue. This increase of colour arises from the injection of the capillaries of the spot, and expresses the condition of true, though limited, capillary hyperæmia. If the catarrhal irritation increases, the patches extend and coalesce, and the colour of the affected part becomes darker; and when the irritation has reached its maximum of intensity, the membrane assumes a bright vermilion-red hue. At this period there is a deficiency in the natural secretion of the membrane, and when the affection is seated high up in the wind-pipe, or extends no farther than the larynx, it is at this stage that hoarseness exists. It may be observed here that catarrhal irritation invariably proceeds from above downwards; and that, supposing the trachea to be the seat of the original catarrhal attack, there would be almost a certainty, that if it extended, it would descend to the bifurcations of the bronchi, rather than ascend to the larynx. This is more particularly noticed in epidemic catarrhs, where the original attack, commencing as coryza, and seated in the Schneiderian membrane, extends to the pharynx, thence to the larynx, and if the attack be severe and neglected, continues to the trachea and bronchi, and ultimately extends to the minutest branches of the air-passages. But the reverse is never observed, the catarrhal irritation never proceeds from within outwards,—from the smaller tubes upwards to the wind-pipe and larynx.

I have already observed, that in the earliest stage of the affection, there is a diminution, even total absence of the ordinary lubricating secretion of the part. The air irritates the undefended and irritable surface, and excites a dry, frequent, and harrassing cough. In the mildest cases, this state of capillary congestion and deficiency of secretion is soon followed by the pouring out of a thin pituitary fluid, which soon presents many minute grey points or striæ, mixed with many air-bubbles. Under the microscope, this secretion is observed to be composed of epithelial cells—even layers of them—in great abundance, suspended or floating in a clear mucous fluid, and often mixed with many granular corpuscles. Proportioned to the intensity of the preceding capillary injection, changes take place in the secretion; it becomes thicker, opaque, slate-coloured, greyish yellow, even yellow, and then assumes a more evident muco-purulent character. As the irritation subsides, this secretion gradually diminishes in quantity and consistence; epithelial cells in diminished number are alone visible, and the mucous membrane gradually and slowly

returns to its normal and healthy condition, regular epithelial layers being formed, as the more superficial are constantly and uniformly thrown off.

In the more severe forms of bronchial catarrh, where a more extended surface of mucous membrane is from the first the seat of morbid action, and where the capillary hyperæmia is not confined to the superficial mucous layer, but involves a more expanded series, and injects even the vessels of the sub-mucous tissue, the term bronchitis more usually applies. The several pathological conditions before noticed, are here much aggravated. The mucous membrane is no longer of a bright rose-red colour, but presents a deeper tint, even madder red; in the case before us purple madder. Consequent on this large amount of turgescence of the capillary vessels, (upon which this change of colour depends,) is tumefaction of the entire series of mucous tissues. A swollen turgid state of the mucous membrane is now observed; the effect of this is a diminution in the calibre of the air tubes,—a coarctation of them,—a lessened diameter. An increased frequency in the respiratory movements now compensates, or is an effort to compensate, for the diminished capacity of the air-tubes; and we notice in the severer forms of the disease, a gasping effort during inspiration, attended by very distinct wheezing sounds on expiration; these are distinctly heard, even without the aid of the stethoscope.

Now all these conditions were present in the case under consideration; and the physical signs recorded in the case book are very expressive of the conditions just explained. There is no respiratory vesicular murmur to be heard, the only sound at first is a sonorous rhonchus, either accompanied or followed by a variety of irregular murmurs, sometimes simulating the gentle cooing of a pigeon, at others whistling and wheezing. The lessened diameter of the air-tubes from the tumefaction of the sub-mucous tissue, is the cause of these sounds. As secretion becomes established, the turgescence of the membrane is relieved, but the air passing and re-passing over and through the tenacious matters in the tubes, produces the bubbling sound, heard so soon as secretion is accomplished, and to which the term mucous rhonchus or mucous gurgling is applied. This sound differs somewhat, according as it emanates from the larger or smaller tubes, and the study of that distinction is of much practical consequence. The mucous gurgling of the small tubes was very palpably present in this case, and you had an opportunity of hearing its peculiarity. When the catarrhal irritation extends to the smaller tubes, a similar series of changes takes place; the secretion at first scanty and thin, accompanied by frequent, urgent, and almost suffocative cough, becomes more abundant, opaque—a yellowish mucus, tenacious and frothy,—and in urgent cases, assumes the qualities of a muco-purulent fluid, in some cases possessing an almost cream-like consistence. This, as convalescence proceeds, becomes again thinner—more fluid, till in the stage of chronic bronchitis it has become a perfectly white frothy fluid, colourless, and oftentimes extremely abundant.

There is yet one other pathological condition in the severe and more acute forms of bronchitis, and of which we have some evidence in this case, which must not be omitted, and that is the presence of plastic exudation; it is also known as fibrinous exudation, and is the inflammatory exudation of Vogel and other modern pathologists. The mucous membrane is as capable of generating this product of inflammatory action as other tissues, although it is certainly not so frequently observed as in the serous and cellular series. It would appear to be dependent on the amount of pre-existing capillary hyperæmia, the intensity of which, instead of generating granular cells, which are rapidly converted into pus-globules, and thus forming a true muco-purulent secretion, is attended by the exudation of a plastic lymph, which fills the smaller tubes and takes their form; and if the disease be fatal at this stage, this coagulated matter may be drawn out from the smaller branches, and in this case you witnessed its tenacity to be sufficient to allow it to be drawn out. In croup this exudative product extends over a large portion of the tubes, and explains the peculiarity of the stringy shreds expectorated in this disease. In the adult, if life be prolonged, this inflammatory exudation soon becomes purulent, pus-globules being very soon generated in it. This change facilitates its excretion, rendering it more fluid, less tenacious, and consequently more easily expectorated.

There can be no doubt, notwithstanding the imperfect history of this case antecedent to admission, that pulmonary catarrh had existed for some time, perhaps in a chronic form, and that in all probability the patient had experienced repeated attacks for some winters past. The enlarged condition of the heart strongly favours this view, for derangement in the structural condition of this organ is one of the most frequent causes of the perpetuation of chronic catarrhal affections of the pulmonary organs. A catarrhal predisposition in the bronchial mucous membrane, and heart-disease, tend to mutual aggravation. The catarrhal condition gives rise to frequent cough, often paroxysmal and suffocative; venous turgescence results. The violent expiratory efforts of coughing convey an impulse back on the right ventricle; in consequence of the disturbance the current of blood suffers from the circulation from the right side of the heart into the lungs being impeded, dilatation of this cavity follows, with a corresponding increase in the general mass of the organ. Increase of volume produces increase of power, and causes the blood to circulate in the pulmonary tissues with a force proportionate to the augmented volume. A condition of passive hyperæmia is perpetually present, which promotes, if it does not originate, the susceptibility to catarrhal irritation. With such predisposing causes it is not to be wondered that acute bronchitis should supervene, and should run a rapid and fatal course. Inflammatory exudation forms in the smaller bronchi; blood imperfectly oxygenated circulates through the left side of the heart, and reaches the great central organs of the frame; its action on the brain is first to induce torpid senses, the countenance becomes livid and purple, the surface becomes œdematous, the dyspnœa becomes more and more urgent, coma supervenes, and death then closes the painful and distressing struggle. The existence of emphysema

on the inferior margins, and on the surface of the lobes, must be taken as collateral proofs of the existence of some long-standing affection of the pulmonary organs, attended most probably by violent expiratory efforts, as in coughing; but the subject and pathological conditions of emphysema I propose to treat of on some other occasion.

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(*Fourth Series of Experimental Researches.*)

By William Addison, M.D., F.R.S., Malvern.

(*Continued from page* 93.)

VII. The Process of Nutrition, or the Reciprocal Action between the Blood and the Solid Textures.

The growth and preservation of all parts of the human body, and the renewal of its textures and secretions, whether healthy or diseased, depend upon a reciprocal action between the blood and the solid parts, termed the process of nutrition, in which certain elements or forms of matter withdrawn from the circulating current, become portions of the fixed solid. If the newly withdrawn matter assume the form of the pre-existing elements of the solid, and the quality of the pre-existing secretion, the process is said to be *normal* or healthy; but if the elements of the solid be changed, or the quality of its secretion altered, in consequence of any unusual change or unconformable transformation which the new matter undergoes, then the process is said to be *abnormal* or unhealthy.

If the circulation of the blood be observed with the microscope, in the nutrient vessels of a transparent texture in the living animal, without any previous rude handling or irritation, the stream is seen rapid and uniform, and it is impossible, from the rapidity of the current, to discriminate its cellular or corpuscular elements, except that here and there colourless cells are seen clinging to the walls of the vessels, slowly gliding along in close contact with them. If the part under observation be irritated, the regularity of the stream is immediately disturbed in a very remarkable manner, and, as if in consequence thereof, colourless cells, in increasing numbers, are observed separating themselves from the red current, and becoming fixed to the walls of the vessels. Soon afterwards, a clear colourless material appears between the stream of red blood and the solid texture, in which the colourless cells seem to be embedded; so that the irritating cause, of whatsoever nature it may be, is productive of an actual and visible separation between the colourless and the red elements of the blood, which is seen to take place within the vessels, the red flowing onward, sometimes with the utmost rapidity, whilst the colourless remain stationary, and form a new interior coating to the vessels (the protoplasma.) We are precluded from making this direct satisfactory and conclusive observation in the human body, because there is no accessible part sufficiently thin and transparent for the purpose; but we have cogent reasons in the analogies of life and function—in the composition of the textures and the blood—for concluding, that in man, analogous or similar irritants are followed by similar results. This conclusion, drawn from analogy, is substantially corroborated by the fact, that in the human body, colourless cells greatly abound in the blood drawn from vessels that are experiencing any irritative or inflammatory action.

But the real nature or meaning of the phenomenon, thus seen in the living vessels of animal structure, and presumed from strong analogies to exist in the human body also, must be interpreted by the result or product—and this clearly proves it to be a phenomenon of nutrition, for the irritated animal textures become thicker, and new layers and new matter appears;—so in the human body where textures are becoming thickened, where new products and new results are appearing,—in pimples, boils and vesications,—in the skin in scarlet fever and erysipelas,—colourless cells are exceedingly abundant in the nutrient vessels, sometimes equalling in amount the number of the red cells.

Hence, therefore, it appears, from proofs accumulated on all sides, that the separation of the colourless cells and protoplasma or lymph of blood, from the red cells, and their distribution in a stationary form over the interior surface of the nutrient vessels are phenomena of nutrition; and it would farther appear from the cellular or corpuscular nature of pus, and from the ready healing by pressure of wounds discharging pus, that if the colourless elements withdrawn from the blood fail to undergo a conformable metamorphosis, or the cells to deliver up their contents, they change the character of the walls of the vessels, alter the anatomical type of the texture, and subsequently appear in the discharges or secretions,—in which case *the whole thickness* and the whole of the matter in the walls of the vessels experience a progressive alteration from within, there being no membranous septum or *structureless membrane* under these altered conditions, standing as a barrier to the retrograde morphology.

The process of nutrition here described from observation and experiment, comprises three intelligible and visible stages:—*First*, the separation of the colourless cells and protoplasma of the blood from the red current; *secondly*, the metamorphoses of these colourless elements in their progress through the walls of the vessels; and *thirdly*, the ultimate product which constitutes the permanent form or textural type. The first stage takes place within the vessels, along their interior boundary; the second takes place in, and gives the form of, the elements of the walls of the vessels; and the third, or ultimate product, appears at the outer

margin and is in fact an extension, of the vascular wall.

These stages of nutrition will be more readily comprehended by referring to the wood engraving, which represents *one half* of the diameter of a small blood-vessel in the transparent membrane of a human embryo, at two months, that is to say, in a texture in a state of rapid growth or active metamorphosis. It was copied from the microscope, and is magnified 750 diameters linear. The dark portion, *a*, is one half of the column of red blood lying in the centre of the vessel; the red cells are many of them nucleated, and larger than in the blood of an adult, and lying obscurely amongst them are several colourless-cells—various in dimensions—some very large and filled with a colourless matter mixed with molecules. At *b* is a transparent layer of colourless matter or protoplasma, lying between the column of the red blood and the wall of the vessel;

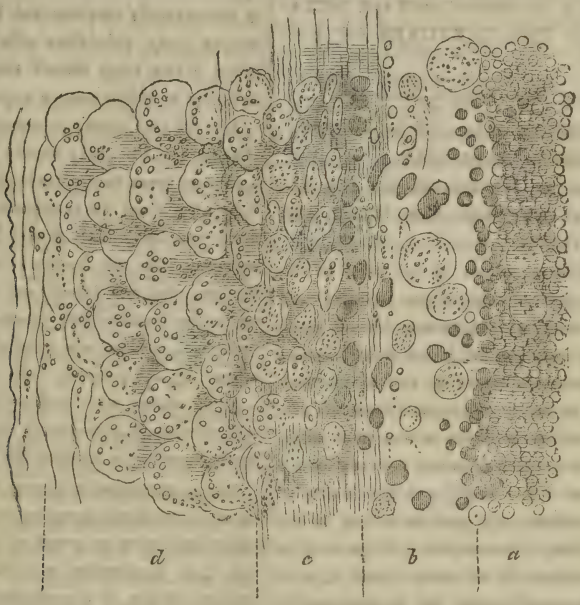

Fig. I.—Half the diameter of a small blood-vessel in the transparent membrane of the human embryo at two months. *a*, column of red blood, *b*, layer of colourless matter, with cells, granules, and molecules, between the red blood and the coherent wall of the vessel. *c*, a texture composed of fibres, cells, and nuclei, forming the wall of the vessel. *d*, the coherent cellular texture forming the membrane.

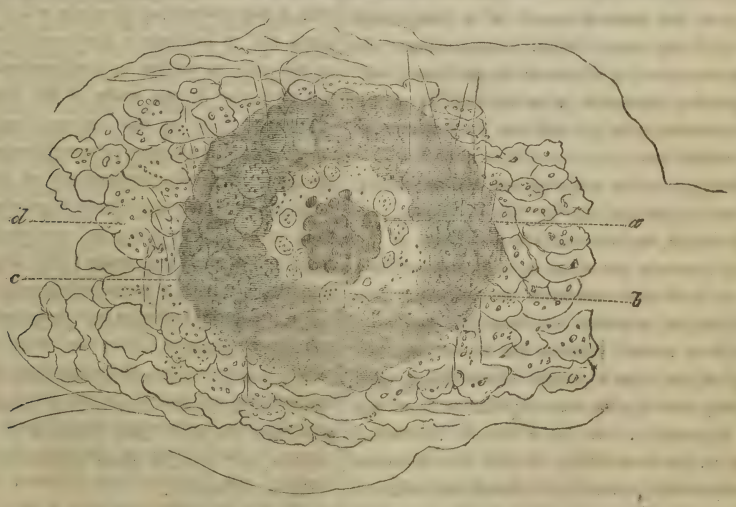

Fig. II.—A section of the same vessel perpendicular tot he axis, shewing the same series, blood, protoplasma, texture, (*πρωτον υφασμα.*) and cellular parenchyma. It appears to me, that the subject of secretion, the growth of the embryo structures, and the phenomena of inflammation, would be more intelligible were we to use terms expressing more accurately *the stages of nutrition*, as revealed by the microscope:—(*a*) blood—(*b*) protoplasma—(*c*) prot-uphasma—(*d*) parencehyma. I well remember the late Dr. George Pearson, five and twenty years ago, insisting upon the distinctions between *coagulable* and *coagulated* lymph.

in it are seen several colourless cells of various sizes, filled with molecules, also smaller granular particles; and numerous isolated molecules. At *c* is the wall or coat of the vessel, (the *prot-uphasma* or first texture,) composed of numerous colourless cells or nuclei embedded in a mass of nascent fibrils, which have, in this example, hardly more coherency than the fibrils of a tough mucus. Granular particles and molecules are seen within these colourless cells or nuclei, and the fibrils pass around and between them. Numerous red cells of irregular shape are seen mingled with the colourless elements,—cells, nuclei, and fibrils,— of the vessel's wall, or coat; but these have all the appearance of being accidental and due to the manipulation necessary to render the texture a microscopic object. At *d* is a portion of the transparent cellular membrane itself—the *parenchyma;* it is evidently an extension or expansion of the wall of the vessel, and no unalterable barrier exists to separate it from the *protoplasma—every element is in progress of change.*

If a section of this vessel were made across it, perpendicular to its axis, we should have a column of blood in the centre *(a)*, consisting of red and colourless incoherent cells, suspended in the blood-fluid; next to it will be a layer of colourless lymph or protoplasma (*b*), consisting of a viscous matter, mixed with molecules and colourless cells; next to that is the proper coat of the vessel (*c*), the first texture varying with the morphology, and consisting in this case of delicate fibres, intermingled with molecules, granules, and colourless cells or nuclei; and lastly, as an extension of the vascular wall, the proper texture or parenchyma (*d*),—this texture shewing what the morphology has been, and the existing vascular wall indicating what it is or will be. A similar section of a vessel that has been irritated in the frog's foot, would exhibit the same thing. Hence, then, the conclusion stated in the *"First Series of Researches,"* p. 30, respecting the analogies between active growth and inflammation, is fully borne out by these subsequent investigations.

These things, let it be observed, are not matters of surmise and conjecture, but of demonstration, and cannot, therefore, be set aside because they do not square with received and hypothetical notions. It is very easy to throw discredit upon microscopical facts and conclusions by a flourish of the critical pen, and a flippant style of remark, little suited to the occasion; but Nature marches on, although the critics write, and is ever ready with intelligible answers to those who faithfully interrogate. A florid appeal to existing sympathies may be for a time successful. Warm-hearted spirits contend stoutly for their convictions; and settled opinions are difficult out-works to carry, though Nature herself be battering at the walls. But those who, in the ardour of their defence, merely uphold their own opinions, when truth and science are rolling onward in new directions, must find themselves at last protecting shadows in the rear.

In bringing my observations for verification to the test of the microscope, I would fain remark, that the observer should bear in mind the minuteness and delicacy of those portions of structure that can alone be submitted to high microscopic power, and the unavoidable disturbances that necessarily ensue when it is requisite to take very thin sections, and therefore that decisions *pro* or *con* should be based not so much upon the isolated results of one or two hasty trials, but rather on the tenor of the indications derived from a greater number.

In any departure from the law of the nutrition of a texture,—from the law of the morphology,—it must be a very difficult question to determine where the first unconformable step commences, whether in the blood *a*,—in the lymph or protoplasma *b*,—in the wall of the vessel *c*,—or in the texture *d*? It is very common to read about diseases of the blood, yet all must be dark and unsatisfactory to any one that has observed the relations between the blood and the textures by means of adequate power through the microscope; and certain it is, that no *practical* conclusions can be established respecting health and disease until the stages of nutrition, the reciprocal actions between the blood and the solid textures, be established. At present the notorious fact of red blood, administering to the rapid increase or deposition of colourless textures, lymph, mucus, and pus, remains, in respect of any well-directed scientific investigation, a *glaring instance* of theory, hypothesis, and conjecture. Critical physiologists seem afraid of using their eyes, though they battle boldly with assertions.

VIII. Inflammation.

When the growth and nutrition of a texture of any kind, whether animal or vegetable, is *normal*, its elements are reproduced or multiplied, its form evolved, and its characteristic qualities and secretions established by a metamorphosis of the nutritive elements, supplied from without, in accordance with the law originally in force in the primary conformation of the parent organism from which it sprung. Every change,—every metamorphosis,—every action,—and every product, yielding or conforming to the law, is an integral element of the complex phenomenon termed health; and every action or product deviating from it, is an element of disease.

It is not my intention now to enter upon the multiplied details of inflammation or inflammatory products; hereafter we shall have occasion to return to the subject, and examine more particularly the nature of its manifold results.

We have seen that any irritation of a vascular texture, is productive of an increased amount of nutritive matter, which is deposited from the circulating blood, upon the walls or inner boundary of the vessels.

The *increased* amount of matter so deposited is a deviation from *the law* of the texture, and therefore a phenomenon of disease; but the sensible or visible effects upon the texture depend upon the times, stages, and forms, of the subsequent morphology, which may conform to the law of the texture, or deviate from it. For example—the *fibrous textures* are not secreting textures; they do not evolve a viscid mucus mixed with cells; this is not the law of *their* nutrition. These textures are therefore on this account called *serous textures*. But there are other textures that do evolve a viscid mucus, mixed with numerous colourless cells, and these are therefore termed *mucous textures*. Now, an unusual amount of nutritive matter, deposited upon the walls of the blood-vessels of a fibrous texture, *and a conformable morphology*, necessarily give rise to an increased amount of the elements of the texture, which becomes thickened by abnormal fibres; and if adhesions are contracted between contiguous surfaces, it is by fibres; and the serous fluid which naturally lubricates the texture, is increased in quantity. On the other hand, an unusual amount of nutritive matter, deposited upon the walls of the nutrient vessels of a mucous texture, *and a conformable morphology*, give rise to an increased quantity of mucus, mixed with a larger number of colourless cells. In either case, an unconformable morphology would produce different forms and qualities—fibrous forms, for instance, upon the mucous textures, and corpuscular forms upon the fibrous textures.

"Inflammation," says a recent and talented author "must needs occupy a large share of the attention both of the surgeon and the physician; it is continually the object of his treatment and watchful care. It affects all parts that are furnished with blood-vessels; and it affects different parts very variously."—"A great majority of all the diseases to which the human frame is liable, begin with inflammation or end in inflammation, or are accompanied by inflammation during some part of their course, or resemble inflammation in their symptoms. Most of the organic changes of different parts of the body recognize inflammation as their cause, or lead to it as their effect; in short, a very large share of the premature extinction of human life in general is more or less attributable to inflammation."—"Again, inflammation is highly interesting, not only in its morbid phenomena and destructive consequences, but in its healing tendencies also. It is by inflammation that wounds are closed, and fractures repaired,—that parts adhere together when their adhesion is essential to the preservation of the individual,—and that foreign and hurtful matters are conveyed safely out of the body. A cut finger, a deep sabre-wound, alike require inflammation to re-unite the divided parts. Does ulceration occur in the stomach or intestines, and threaten to penetrate through them? Inflammation will often anticipate and provide against the danger, glue the threatened membrane to whatever surface may be next it, and so prevent that worst and universal inflammation of the peritoneum which the escape of the contents of the alimentary canal into that serous bag would infallibly occasion. Inflammation, limited in extent, and moderate in degree, becomes conservative by preventing inflammation more severe and more widely-spread, which would be fatal."*

This being the graphic picture of inflammation by a practical physician, the question very naturally arises, what *can* this inflammation be?

In the first place, the answer appears to me to be clear upon this point,—that the inflammation which is conservative,—closes wounds—repairs fractures—has healing tendencies—and preserves the life of the individual,—must be different from the inflammation which produces destructive consequences—morbid phenomena—organic changes—and prematurely extinguishes human life; and therefore, that two very different, nay, opposite and incongruous things, are brought together under the unscientific and silly term of inflammation. The difficulties of the subject obviously arise, not from an oversight of the primary phenomenon, the disturbed circulation of the blood, and the increase of nutritive matter in the vessels of the affected texture, but from an utter neglect of the physiological elements involved, and therefore, necessarily of the conformability or unconformability of the morphology. A nutritive element,—that is, an element of growth, nutrition, or secretion,—which is conformable and therefore healthy in one texture, is unconformable, and therefore an element of disease, in another and different texture. An unusual abundance of colourless corpuscles or cells and an increased mucous secretion in a mucous texture, may pass under the term inflammatory product; but mucus and mucous cells are conformable products, and an unusual amount denotes no more than an increased amount of the elements natural to the texture; whereas, the very same elements in a fibrous or serous texture or in the fluid evolved from it, are *the* proof of an unconformable metamorphosis, because such incoherent forms are not natural to this texture.

If so complex a subject as normal and abnormal nutrition,—of conservative and destructive inflammation—be susceptible of a short definition, it may be said, *that simple healthy inflammation consists of an increased amount of protoplasma with a conformable morphology; and destructive unhealthy inflammation, of an increased amount of protoplasma with an unconformable morphology*. The terms conformable and unconformable, referring to the law which governs and determines the physiological form and function of the texture in health, and which must be known before the nature of

* "Lectures on the Principles and Practice of Physic," (in the *Medical Gazette*,) Dr. Watson.

the diseases can be understood. It is not necessary to this definition of simple healthy inflammation, that *all* the nutritive elements furnished by the blood should undergo a conformable metamorphosis; it is sufficient that they do so within a reasonable time, to the extent of restoring the irritated, wounded, or inflamed texture to its normal state and function.*

Practical medicine is based upon the recognition and appreciation of visible or sensible signs: the physician cannot treat diseases ascertainable only by the microscope; but if this instrument carries our analysis of change of texture into hitherto unknown regions, the medical practitioner must be prepared to accept or reject its testimony *in toto*. There can be no halting between the microscope and the eye,—interpreting one part of physiology and pathology by the vision of nature, and another by the improved vision of art. If the microscope is to be relied on as an analytical means, then not only is every *post-mortem* examination imperfect and the majority useless without it, but we must no longer speak of vessels or ducts secreting. Vessels convey or transmit incoherent corpuscular forms, and are the means of their accumulation; and ducts convey them away *out of the body*. Transformations of matter are effected, or secretions formed, within the cells.

* The phenomena of inflammation, although very multitudinous, may in fact be resolved into the morphology of the contents of individual cells, the conformability or unconformability of the product being dependent upon the normal or physiological type of the elements of the texture, and the form resulting from the last stage of the inflammatory metamorphosis. This is shewn by the phenomena of inflammation in the several textures of the lung,—pleurisy (*fibres,*) bronchitis (*cells and mucus,*) and *pneumonia (a mixed product.)* I would beg to suggest to Mr. Hassall the benefit he would confer on physiology and pathology, by extending his "Microscopical Anatomy," so as to include the elements of the various parenchymata, and the structure of their nutrient vessels in the embryo and in the adult, viewed with a power of 600 or 700. If these were correctly established, the phenomena of scrofulous diseases and inflammation would be rendered easy.

(To be continued.)

CASES AND NOTES FROM HOSPITAL AND PRIVATE PRACTICE.

By C. M. Durrant, M.D.,
Physician to the East Suffolk and Ipswich Hospital.

(*Continued from page* 547, *of last Volume.*)

Case XVII.

CIRCUMSCRIBED EMPYEMA, COMMUNICATING WITH THE BRONCHI: ABSCESS OF THE LUNG: PHYSICAL SIGNS: TREATMENT: RECOVERY.

J. M——, aged 27, a labourer, admitted into the Ipswich Hospital, September 3rd, 1846, under the care of my colleague, Dr. Beck, who being prevented visiting the hospital at the time, the case in part fell under my observation.

He stated, that seven weeks prior to his admission, he was siezed with rigor and pain in the right side, succeeded by slight cough, at first dry, subsequently with some expectoration. He attributed his illness to drinking a pint of very cold water from a spring, when greatly heated by hay making.

The symptoms on admission were thus noted:—Complexion muddy; tongue tolerably clean; bowels regular; urine natural; pulse 80, of good strength; cough not very urgent; expectoration muco-purulent, having a peculiarly unpleasant sickening odour.

Physical signs.—Inspection: Evident bulging of the antero-inferior region of the right side of the chest, from between the third and fourth ribs downwards, the affected portions rising *en masse*; vocal and tussive vibration not particularly noted.—*Percussion:* Complete dulness over the anterior and lower part of the right side in front; normal sonorosity behind; the left side healthy.—*Auscultation:* Total absence of breath-sound over the lower-third of the right lung in front; slightly exaggerated in the antero-superior region of the same side; fistulous breathing audible between the fourth and fifth ribs; respiration natural over the back; no abnormal rhonchi; resonance of voice and cough unaffected; left lung healthy.

These phenomena continued for about a week, with but little variation, the pulse remaining at 80, soft, and of moderate strength; tongue clean; appetite excellent, and bowels regular. At this period the patient became suddenly worse; he had a rigor; the skin was hot; the cough greatly increased; expectoration purulent, the odour from which was now scarcely bearable; he had nocturnal perspirations, and evidently emaciated; the pulse, however, remained steadily at 80, of fair tone, and the appetite continued tolerably good. There was occasional vomiting, which was justly attributed to the horrible fœtor of the expectoration. On examining the chest, the respiratory murmur was now feebly audible over portions of the affected region, on the right side in front, in which it had hitherto been extinct; the fistulous breathing had disappeared, and about two inches to the outer side of the right nipple, and a little above that projection, there now obtained, in addition to a modified amphoric stroke sound, cavernous breathing, loud bronchophony, and slight gurgling, clearly indicative of a pulmonary abscess. The vesicular murmur immediately around this spot was healthy.

Treatment. This consisted of counter-irritation by means of two successive blisters to the side, followed by antimonial pustulation, mercury (Hydrarg. cum Creta,) to affect the gums, the influence of which was prolonged, salines; subsequently the iodide of potassium, creosote internally, and by inhalation; and lastly, quinine and nitric acid, with the syrup of the iodide of iron. The diet, with the exception of the first few days after admission, and the period of the rigor, was "full" throughout—viz., meat daily, with a pint of porter. Under the above treatment the patient rapidly gained flesh and strength, the cough subsided, the expectoration became less, with diminished fœtor, and the progress of the case towards recovery, although slow, was uninterrupted. He was discharged perfectly well, the respirations being fairly audible

over the entire lung, with but comparatively slight falling in of the lower ribs.

Remarks. The phenomena of the preceding case, although full of practical interest, are so clearly developed both by the general symptoms, and also by the physical signs, that it sufficiently elucidates itself; still a passing remark upon one or two points may not be deemed superfluous.

That the patient was correct in ascribing his illness to the draught of cold water taken when heated, there cannot be a question. In our agricultural districts during hot weather this dangerous practice becomes, I believe, not unfrequently a rife cause of internal disease among the labouring classes.

The history of the case, the aspect of the sufferer, the cough, and the peculiar expectoration, at once aroused suspicion of some formidable chest affection. That such existed was most unequivocally revealed by the stethoscopic examination; indeed I do not remember to have seen any case in which the phenomena described in the report were so clearly developed. The bulging of the lower ribs, the circumscribed dulness, with corresponding absence of respiration strictly limited to this spot, at once bespoke the presence of a fluid, enclosed by pleuritic adhesions; while the co-existence of fistulous breathing with the fœtid expectoration, farther indicated that nature had already formed an exit for the discharge of the foreign matter.

The occurrence of abscess in the lung was an unusual feature in this case, its formation was so rapid as to lead to the probable belief that its origin resulted in the introduction into the venous system of purulent matter, followed, as we see in the liver and other parenchymatous organs, by suppurative inflammation. With the exception of a very few days, two most favourable circumstances obtained throughout the progress of the case—viz., the continuance of appetite, and an unvarying steady pulse, seldom above 80, and of moderate strength. When these conditions present, in the absence of tuberculization of the lungs, we shall, I think, for the most part be justified in giving a favourable prognosis.

Cases of this kind require support almost from the onset, steadily having recourse, however, at the same time, to repeated counter-irritation. The creosote in this instance was administered both internally and by inhalation, and as in gangrene of the lung, and other affections in which the expectoration is offensive, with the result of lessening, and finally removing, the fœtor.

Case XVIII.

INFLAMMATION OF THE DIAPHRAGM.

F. S———, aged 34, a tailor, admitted into the Hospital February 18th, 1846. States that he enjoyed good health until about eight years ago, when he had an attack of acute rheumatism. From this he recovered, but has since been the subject of two or three similar seizures. About eight months since, while labouring under a severe attack of rheumatic fever, he was seized with a sudden and severe pain, of a constrictive character, extending completely across the body from one hypochondrium to the other, accompanied by great tenderness on pressure, dyspnœa, cough, palpitation, and, as reported by his wife, considerable delirium. On the occurrence of the pain in the body, the rheumatic pain of the joints became greatly lessened. The patient stated that on different occasions, unconnected with the present attack, he had expectorated large quantities of blood, amounting altogether to between one and two gallons. Of the accuracy of this statement I am sceptical, although the patient adheres most rigidly to the circumstance of the blood being ejected by cough and expectoration, and not by vomiting. On his admission his general appearance was strongly that of advanced phthisis, so much so that I confess that before making an investigation of his case, I was fully prepared to find extensive tuberculous disorganization of the lungs.

His countenance was anxious and exsanguine; eyeballs prominent; tongue coated; total anorexia; bowels sluggish. He complained of a violent sharp burning pain, with great tension and constriction across the lower part of the thorax, extending between the hypochondria and beneath the sternum, and stretching to the loins, and which was greatly aggravated by coughing, sneezing, and deep inspiration. Pressure between the lower ribs, over the epigastrium or hypochondriac regions, and more especially pressure on the abdomen upwards, towards the diaphragm, caused most acute suffering. Respirations short and hurried, and chiefly performed by the intercostal muscles, with slight short dry cough; pulse small, quick, and very weak, and beating irregularly in the right radial artery.

The chest sounded tolerably resonant throughout on percussion; respiratory murmur was audible over both lungs, slightly deficient at the left apex in front; action of the heart weak and irritable, but regular; its sounds unaccompanied by bruit.

Treatment. From the extreme anæmia and general weakness of the patient, neither general nor local depletion appeared admissable. Two grains of calomel with one grain of opium, were given night and morning; a mixture containing an excess of alkali, with spirit of nitrous æther, and small doses of the tincture of colchicum, was directed to be taken three times a day, and a blister, encircling one half the body, was applied to the left side. On the mouth becoming sore, the opium was continued without the calomel, and the subsequent progress of the case to convalescence was uninterrupted. On his discharge from the hospital he was perfectly free from pain, bore firm pressure without complaint, the cough had ceased, but the pulse in the right arm remained irregular, and the respiratory murmur in the apex of the left lung, although more perfect, yet less pronounced than in that of the corresponding side.

I have since heard that he has been the subject of a similar attack, but I have not been able to ascertain the result.

Remarks. While inflammation of the serous covering of the diaphragm, in connection with its contiguous extension over the pleura and liver, is by no means uncommon, inflammation of its musculo-tendinous structure is, I apprehend, decidedly rare. In the foregoing case, the affection was associated with

rheumatism, the extension or repression of which disease is, perhaps, one of its most frequently exciting causes.

The symptoms from the first were well marked, and require no comment. Upon what the permanent irregularity of the pulse in the right radial artery depended, I am not prepared to say, the stethoscope did not indicate either cardiac or arterial disease; it arose, in all probability, from local pressure upon the artery, but in what part of its course this obtained, repeated examination failed to elicit.

In the treatment, in addition to the other remedies, I am disposed to attribute a large share of the benefit derived to the free use of opium; and this leads me to allude briefly to the question lately brought before the Association,—viz., "The treatment of internal inflammation, by opium," an important practical subject, and one which I trust that we shall sooner or later see discussed in the pages of our Journal, by not a few only of its many talented members. Without entering upon the theory of the action which opium exerts upon healthy and diseased organs, I can most fully assent to the opinions which have been recently expressed by Drs. Chambers and Ranking, in reference to its utility in the treatment of many cases of acute internal inflammation. The power of allaying pain, subduing nervous excitability, and thereby reducing the irritability of the heart's action, peculiarly belongs to this drug; and however difficult or impossible it may be to instance, by writing, those particular conditions in which its adoption is so generally followed by benefit, still how vividly will the reflecting physician, unshackled by hypothetical notions, revert to the satisfactory results which in his hands have attended its use.

In the selection of the cases most requiring the opium treatment, as also the precise period at which this medicine is called for, (and this is all important,) medical tact and observant experience can alone direct. A volume upon the subject would, in many instances, utterly fail to indicate the peculiar circumstances requiring opium, but in which to give it is recovery to the patient,—to withhold it is probable destruction; and who cannot call to mind the look of gratitude beaming in the countenance of the sufferer relieved, if not rendered out of danger, by the timely and judicious exhibition of this valuable drug. Independently of those diseases in the treatment of which opium is commonly prescribed, as delirium tremens and some other nervous affections, there exist others, in which at one period or other of their course, the exhibition of opiates is attended with the happiest results.

In the second stage of pneunomia, if the cough be constant and harassing, the expectoration scanty, and the countenance anxious, with an exalted state of nervous sensibility, full doses of opium at bed-time often act like a charm. In pleurisy, prior to effusion, the same medicine administered at night, giving mercury *per se* during the day, is equally valuable. If effusion obtain, the balance of the circulation is often so much interfered with, that the propriety of opium, in these cases, becomes questionable. In rheumatism, the best effects result from opiates; but in this disease, as in pleurisy, I believe that more benefit will be derived from administering opium in full doses at night, with mercury during the day, instead of the more common practice of combining the two remedies. In croup also, in lymphatic children, after the urgency of the symptoms have abated, opium to prevent spasm is often imperatively called for. In peritonitis, enteritis, diarrhœa, and dysentery, opium judiciously used is invaluable.

The forms which I myself prefer are the crude opium and the muriate of morphia.

In reference to the constipating effects of this drug upon the bowels, I do not regard it as any reason for withholding its use. In enteritis and peritonitis, it becomes often of paramount importance, while allaying pain, to ensure quietude in the intestinal tract; and not unfrequently shall we find obstinate constipation attended with, and perhaps produced by, spasm, effectually relieved by the free administration of opium. Within the last few weeks, I have witnessed the most decidedly beneficial result obtain from the exhibition of opium, in strangulated irreducible hernia, for the relief of which, neither the patient (a female, aged 64,) nor her friends, would sanction an operation. After all other measures had been adopted, by the surgeon in attendance, without avail, and repeated stercoraceous vomiting taking place, a grain of solid opium was administered every two hours, with the effect of not only allaying the vomiting, but also (after half a drachm had been taken,) of inducing free and repeated evacuation of the bowels, which function had not previously been performed for fourteen days. The patient, although relieved from the consequences of the hernia, ultimately sank from exhaustion, the friends pertinaciously refusing a *post-mortem* examination.

In thus briefly advocating the powers of opium in the treatment of internal inflammation, I must again repeat, that it is clinical observation alone that will suffice to demonstrate, in many instances, the particular time and circumstances by which its exhibition must be regulated. When calculated to benefit, the relief which it affords is often immense, while on the contrary, if given under disadvantageous conditions, its injurious effects may be irreparable.

(*To be continued.*)

A CASE OF DYSMENORRHŒA IN WHICH THE TINCTURE OF CANNABIS INDICA WAS EMPLOYED, WITH SOME OBSERVATIONS UPON THAT DRUG.

By Benjamin Barrow, Fellow of the Royal Medico-Chirurgical Society, of London.

In offering the following observations to the perusal of the profession, it must not be supposed that I consider the *usual* effects of the hemp to be those which came under my notice in the case in which I employed it, but simply that they are *some* of those which *may* occur and cause much alarm not only to the patient and friends but also to the medical attendant. It is

my desire in giving these details to put those practitioners who may not have employed the cannabis upon their guard as to its administration, for my own part I shall not again give it in any case wherein the uterus is at fault, knowing as I now do what *may happen*, and as I shall presently show, how long the uncomfortable and painful sensations about that organ may continue after its exhibition.

The Cannabis Indica, being one of those drugs, the use of which has been, I believe, very limited, and of which little is known, it may be interesting to some and useful to others of our profession to have a few particulars of the plant and preparation laid before them, as also a brief outline of the experience of those who have employed it as a medicinal remedy. I find that Dr. Pereira, to whose able work on Materia Medica I may refer for full information, represents the Cannabis Indica as possessing no specific qualities different from the Cannabis sativa, which is, as of course all know, the common hemp. Some botanists have, however, stated that there are certain slight differences in the growth and flowering of the plants.* The ordinary dose of the tincture prepared from these plants appears to be from ten to twenty drops; in some cases even as much as a drachm has been given, and without producing effects of any kind. Dr. Pereira, as well as others, has experimented with the drug, and witnessed various effects in different individuals, but none exactly similar to those which were present in the case I shall directly relate. The Indian hemp is mentioned as causing a very agreeable kind of delirium, augmented appetite, venereal excitement, and impaired volition, followed by insensibility, during which the patient retains any position in which he may be placed; its effects, therefore, simulate catalepsy. Dr. W. B. O'Shaughnessy, of Calcutta, has written upon this subject, and his observations upon these preparations may be consulted with advantage. He has described their effects on the animal system in health, and their utility in the treatment of tetanus and other convulsive disorders. Dr. J. Clendinning gives a favourable account of the drug, and says "its exhibition was followed with remarkably few exceptions by manifest effects as a soporific or hypnotic in conciliating sleep, as an anodyne in lulling irritation, as an antispasmodic in checking cough and cramp, and as a nervine stimulant in removing languor and anxiety. These effects were observed in both acute and chronic affections, and in patients of all ages and both sexes. It had also the advantage of not producing the injurious effects of opium. The following is a faithful record of the circumstances which attended the case which came lately under my care:—

A married lady, twenty-six years of age, of a thin spare habit, of a naturally feeble constitution, and who had suffered for some years from dysmenorrhœa, the pain at these periods being of a more than ordinary severe character, requested my attendance in consequence of the extreme suffering with which the last period was ushered in. On previous occasions, I had only been able in any way to alleviate her sufferings, by administering very large quantities of opium or morphine, both of which remedies had been given in every form, but had become so obnoxious to my patient, inducing excessive nausea and vomiting, which frequently lasted for many subsequent days, that I determined to make trial in this instance of the tincture of the Cannabis Indica, my attention having been directed to this remedy and its use recommended, by a much valued and professional friend. I therefore immediately gave five drops for a first dose; in two hours the same quantity was again given, and in three hours five additional; so that in the course of five hours not more than fifteen drops were taken. That this quantity was not exceeded I am certain, since I took the precaution of myself dropping the doses into separate glasses before I quitted the patient. Some ease was experienced after the last dose, and I found my patient tolerably comfortable in the afternoon, but somewhat drowsy, of which I took no particular notice, knowing she had passed but a restless night.

She rose at five o'clock, and went down stairs to dinner at six, at which meal she ate about as usual, and drank one glass of wine. A degree of incoherence of manner and speech was observed by her family during the meal, and almost immediately afterwards she became violently sick and vomited, being at the same time altogether unconscious; the extremities and body became cold, and when I saw her she was perfectly pulseless, the eyes wide open and staring, the pupils somewhat contracted and quite insensible to the strongest light, with strong convulsions of the whole frame, and involuntary twitchings of the muscles, which symptoms remained for a day or two whether awake or asleep. This state of complete insensibility, I might almost say of lifelessness, lasted for about a quarter of an hour. Warm brandy and water, sal volatile, and warmth to the extremities and abdomen had the effect of recalling the circulation, and allaying the other formidable symptoms, but there remained during the whole night a partial state of unconsciousness, as also the other symptoms in a milder degree. The pulse, which varied from 100 to 140 or 150 was extremely feeble, and intermitted from time to time during the following two days.

It is unnecessary to say more of the case, than that the recovery went on progressively under the careful administration of stimulants, although the pains and uncomfortable sensations about the uterus and its appendages continued for a fortnight or longer, which I can only attribute to the medicine, as she had never suffered in a similar way at the termination of any former menstrual period. Warm baths and opium plaster over the hypogastric region, with occasional small doses of hyoscyamus with camphor mixture, tended to relieve these last remaining symptoms.

There are a few observations which it may be useful to make before concluding, but which I shall say in as few words as possible.

The subject of the above case had never suffered at any time of her life from any description of fit or cerebral affection, and her heart, so far as external

* The "Botanical Magazine," Vol. ii, N.S., gives a full description of these plants, by Dr. Hooker.

examination can prove, is free from all disease; so that the failing of the circulation so completely may fairly be attributed to the effects of the cannabis. There is one point particularly worthy of note,—viz., the length of time that the symptoms came on after the administration of the medicine; and I would ask, had she remained quiet in the recumbent position, would the more violent symptoms have been avoided? Upon all those points which appear of interest, and upon the effects which others have observed to follow the exhibition of the cannabis, I am most anxious to learn their experience; and in order to gain such information, I have been induced to lay thus at length before the readers of the *Provincial Journal*, the foregoing case and observations; and feeling, moreover, as I do, most strongly, that it is the duty of every man to give to his professional brethren the advantage of his experience, which important object this Journal is so well calculated to carry out.

Clifton, February, 1847.

CASE OF POPLITEAL ANEURISM TREATED BY COMPRESSION.

By Albert Napper, Esq., Surgeon, Guildford.

Mr. M——k, aged 70 years, a healthy looking man, of tall spare frame and temperate habits, consulted me on the 23rd of August, 1846, for a swelling in the left ham. On examination, I discovered a tumour about the size of a hen's egg, soft and yielding in the flexed position of the limb, but tense and elastic when in an extended state, and projecting considerably beyond the level of the flexor tendons. He had first noticed it about six weeks before, when it was the size of a walnut, and it had gradually increased to the present size. The land which he farms is in some parts very steep, and he attributes the injury to the strain on the limbs in climbing the hills. By careful examination, a distinct pulsation can be felt in the tumour, which becomes flaccid on compressing the femoral artery. No bellows-murmur can be detected, and the pulsation in the lower part of the femoral artery is very weak.

25th. Applied a moderately thick piece of sole leather, previously softened in hot water, over the popliteal space, extending about six inches above and below the joint, and four inches wide, and a similar piece on each side, so as to envelope the limb, with the exception of a narrow space on the upper surface, over which a bandage, sufficiently tight to obtain an exact mould of the inclosed parts. Is not to be confined, but directed to abstain from much exercise.

27th. Removed the leathers, which were well adapted to the joint; but as that covering the tumour did not appear to possess sufficient resistance, it was lined with several layers of lint, steeped in a mixture of white of egg and flour, and over that a thin piece of leather, softened in hot water, and again adjusted as before.

30th. Removed the splints; the lower one is now firm and resisting as a board, and has a complete mould of the tumour.

Sept. 1st. The splints were again removed, and the tumour found in much the same state.

6th. Finding no alteration, I determined on trying the effect of direct pressure on the tumour; I therefore placed upon the swelling several layers of lint, steeped in white of egg and flour, to the thickness of half an inch or more, and again applied the splints firmly. Up to this time he has continued to ride on horseback, but is now to be confined to the house.

8th. Tightened the bandage without removing the splints.

12th. Finding, on removal of the splints, that the compress had only had the effect of flattening the tumour, in which the pulsation is still to be felt, I determined on applying a more effectual compress. I therefore placed the half of a wine cork, split longitudinally, just above the depression in the splint, corresponding with the tumour, and covered it with lint steeped as before, in white of egg and flour, so as to obtain a direct pressure on the artery, immediately above the sack. The splints were then adjusted as before, but with the addition of three or four broad tapes with buckles, firmly stitched to the lower splint to prevent any displacement, and which I afterwards found to be much more effectual than the bandage alone. Assuming that, from the pressure already applied for the space of seventeen days, during which time the patient had not been restricted from exercise of the limb, the collateral circulation was somewhat established, I applied the splints by means of the tape straps, sufficiently tight to nearly or quite obstruct the circulation through the sac, but before leaving my patient, who resides at some distance from me, I gave instructions to his wife as to the management, in the case of the limb assuming a state of venous turgescence. He is now directed to keep the recumbent posture.

15th. Appears to be doing well. His wife informed me that within an hour after I left him on the 12th, the leg became exceedingly turgid and of a deep purple hue, accompanied with numbness and loss of temperature, but through her judicious treatment, this was subdued by slightly loosening the lower strap, and applying friction with warm fomentations. From this time no alteration was made except an occasional tightening of the straps, until—

Oct. 3rd. Removed the splints; tumour much diminished and flaccid, but no pulsation to be detected; a small vessel is felt pulsating over its surface. The ends of the cork, from being left too sharp, have produced slight excoriations of the skin. This was rectified, and the compress adjusted as before.

11th. Removed the splints; tumour much diminished; compress re-applied as before.

15th. The cork compress was now replaced with one made of tow wrapped in lint; the tumour scarcely to be felt.

18th. Continues to improve; he now walks out every day.

Nov. 27th. The leather splints producing but little inconvenience, have been worn to the present time, though I believe for the last month they have been quite unnecessary. They are now removed, and a simple bandage applied. The artery can be felt as a hard cord in the recent situation of the tumour, and the

small vessel above alluded to, pulsating immediately over it.

January 22nd, 1847. On visiting Mr. M—— to day, I found him as well as before the occurrence of the aneurism. A distinct pulsation can be felt in the anterior and posterior tibial arteries.

The difficulty experienced in all the cases hitherto reported, of keeping the compress on the femoral artery, and the pain produced by its pressure on the saphenus and branches of the crural nerves, induced me to try the above method of compressing the artery on the popliteal space; but had I felt disposed to treat my patient by means of any of the ingenious contrivances invented for the purpose, I should probably have failed, owing to the distance (seven miles,) at which he resides from me. The complete success of the above simple method of treatment I trust will be a sufficient apology for my offering it to the notice of the profession, and though it may not be applicable in every case, I believe in the majority of cases seen in an early stage it will be found successful. I think an improvement might be made by removing a portion of the splint, corresponding with the seat of pressure, just large enough to admit the pad of a tourniquet, by which means any amount of pressure might be applied without a possibility of the least displacement of the compress, and with a little contrivance, aneurisms in other situations might be similarly treated.

It is worthy of remark, that during the whole course of treatment the patient suffered *no pain*, though I now believe the pressure was kept up considerably longer than was necessary. He also during the whole time *walked* every morning into an adjoining room, and back in the evening, and was allowed to vary his position in bed as he felt disposed.

Guildford, January 27, 1847.

CASE OF SUPPLEMENTARY SPLEEN, CAUSING DEATH FROM THE PATIENT BEING PLACED IN THE SUPINE POSITION, IN CONSEQUENCE OF A FRACTURED THIGH.

By W. H. Bainbrigge, Esq., F.R.C.S., Surgeon to the Northern Hospital, Liverpool.

May 5th, 1845, James Hughes, aged 53, a groom, of temperate habits, was admitted into the Northern Hospital under my care. While exercising a horse, a short time before his admission, the animal reared, and fell upon him; he was immediately brought to the hospital, and found to have a simple fracture of the left thigh, which was put up in the usual way with the long splint. He went on very well for two or three days, when he complained much of pain in the back, which was relieved by placing a pillow under it. In the evening he complained of swelling of the abdomen, which was tympanitic, but free from pain. The bowels had not been opened since the accident. A turpentine injection, a dose of castor oil, and turpentine fomentations to the abdomen were prescribed. The enema returned without bringing away any fæcal matter, but there was a free discharge of flatus.

Next day, May 8th, the tympanitis continued; he had vomiting and occasional hiccough; no pain or tenderness of the abdomen; countenance depressed; pulse not much accelerated, and of good strength; urine rather diminished in quantity, but not considerably so; tongue moist; thirst. A large quantity of warm water with some turpentine was thrown into the colon with the long tube; it immediately returned without any fæcal matter, but occasioned an escape of flatus, which afforded some relief. Afterwards five grains of calomel were given, and repeated in three hours; this allayed the vomiting for a time, but did not produce any evacuation. He says that several years previous he was affected in a similar way, and that the constipation continued for five or six days, the greater part of which time he was obliged to lie on his back in consequence of an injury. A dose of castor oil and turpentine was given, but immediately rejected by the stomach. He continued to get worse; the vomiting and hiccough were incessant. Expressing a desire to be placed on the night-chair, his wish was acceded to, but nothing was passed.

On the morning of the 10th the long tube was again used, it passed up freely, and a very large injection of warm water and turpentine was given. On the injection returning there was a pretty free discharge of dark-coloured fluid fæces. The vomiting and hiccough continued, but were temporarily relieved by æther and opium, and the bowels acted pretty freely several times. He became gradually worse, and died on Monday, 12th. For the last two days it was requisite to draw off his urine, which was abundantly secreted. The vomiting, hiccough, and tympanitis, continued to the last, but without pain or tenderness of the abdomen.

Autopsy. Intestines generally distended; no traces of peritonitis. On pushing the small bowels on one side, a tumour about the size of a duck's egg was observed lying on the pelvis, and connected with the great omentum, which it dragged down, and formed a band of cord which passed in front of the large bowel at the commencement of the rectum, pressing it against the posterior part of the brim of the pelvis. When on his back the tumour would necessarily fall into the cavity of the pelvis, and cause the cord of the omentum above described to exert so much pressure on the bowel as to impede its functions. On further examination the tumour was found to be a supplementary spleen, enclosed between the layers of the omentum, and receiving for its supply one of the divisions of the splenic artery, which in fact divided into two branches, one to each spleen.

The above case is chiefly interesting in a physiological point of view. Pathologically regarded, (beyond the circumstance of death being caused by the pressure of the contracted portion of the great omentum,) it possesses no feature of practical interest, as there were no means of ascertaining that this pressure was caused by the position of the patient, and that of the supplementary spleen. It is, however, interesting, as being one fact more added to the list of anomalous cases of the kind on record. Singularly enough accidental change of posture on the part of the patient would have removed the mechanical obstruction, and saved

life, as it seems to have done in the previous attack of constipation. The existence of accessory spleens is a well-known physiological fact; their occurrence, however, is very rare; their varieties are numerous, and they are usually found in the lower extremity of the organ, not far from the fissure either in the gastro-splenic ligament, or, as was the case in the present instance, in the great omentum. Their form is commonly round. That found in this case was in shape precisely like that of the spleen itself, and that it was identical in structure will appear from the following statement, for which I am indebted to Dr. Inman, who was so kind as to examine it microscopically for me:—

"The spleen you exhibited last night possesses conclusive proofs of identity in the peculiar disposition of the arteries and veins in its tissue, in its well-marked fibrous and trabecular character, and the remains of the Malpighian corpuscles, in the existence of a few distinct granules with the remains of others, and in the complete absence of anything like a microscopic cell-structure."

DISSECTION OF THE EARS OF A DEAF AND DUMB PATIENT.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I beg to enclose the notes of a dissection of the ears of a deaf and dumb patient, which were kindly sent to me by Mr. Crosse, to whom I beg to return my sincere thanks for the opportunity he has afforded me of investigating the pathology of the ear; for I feel confident that the only way of throwing light upon the nature of deafness, is to make extended researches into the various morbid changes which take place in the organ of hearing.

Yours, very faithfully,
JOSEPH TOYNBEE.

12, Argyll Place, London,
Feb. 19, 1847.

NOTES OF THE CASE BY MR. CROSSE.

"The patient was 47 years old, or thereabouts, when he died; he was deaf and therefore dumb from birth; his intellect was good enough for him to support himself for many years as a *weaver*, but about fifteen years since he was so reduced as to enter a Union House, and after being there five years showed such a degree of mental derangement that he was placed in a pauper-lunatic asylum, where he remained until he died. He was for a time very maniacal, but subsequently became quiet, and was subject only to occasional attacks, making himself very useful in the asylum in the intervals. I found the cerebrum very vascular on *post-mortem* inspection; an unusual number of vessels, situated chiefly in the medullary substance, discharging their blood on a section being made. The cerebellum was not more vascular than is healthy. I observed no other anormal state of the auditory apparatus. The calvarium I still retain, but shall be glad to send it up, if required, that it may be joined to the rest of the bones of the head, to show the actual size of the brain-box, which indicates that the brain was altogether of rather smaller size than is usual.

"J. G. CROSSE.

"Norwich, February 1, 1847."

DISSECTION.

Right Ear.—The *meatus externus* is full of cerumen of a dark-brown colour.

The *membrana tympani* is of a dull white, and somewhat thicker than natural. The epithelium covering its external surface is denser than usual, and its internal mucous layer thick and soft. The middle proper membrane is also hypertrophied. The cavities of the tympanum and the mastoid cells are completely filled with a secretion of a leaden white colour; it is thick, and in some parts rather viscid. Upon microscopic examination it was observed to consist principally of pus-globules pervaded with granules, characteristic of scrofulous matter.

The mucous membrane of the tympanic cavity is much thicker than natural, it is very soft and contains large tortuous vessels full of dark coloured-blood. The ossicles are quite enveloped, and in a great measure concealed from view, by this thick membrane. The only part of the stapes discernible, is the point where it joins with the incus.

The Eustachian tube is healthy.

The auditory nerve and cochlea appear quite healthy; the fluid in the vestibule and semicircular canals is quite transparent, but the membranous labyrynth is rather thicker than natural, and under the microscope it is seen to contain numerous blood-vessels; the superior semicircular canal is incomplete at its posterior half, and the posterior canal is almost wholly absent.

The *left ear* is in a similar state to the right, excepting that the external meatus is slightly contracted, and the layer of bone separating it from the cavity of the mastoid cells is partially absorbed at the posterior surface of its internal extremity for a space of five or six lines in circumference. The membrane covering this portion of bone, which from its two-fold functions may be called the cutaneo-periosteal membrane, is thick and vascular, and its blood-vessels directly communicate with those of the mucous membrane of the mastoid cells.

I have observed an absorption of the layer of bone between the external meatus and mastoid cells in other instances, and in one dissection the cerumen was found projecting from the cavity of the meatus into the mastoid cells. It is not improbable that the absorption of the bone is caused by the constant pressure of hardened cerumen. The superior semicircular canal was almost wholly wanting. As some dissections of the ear of deaf and dumb patients have been recorded in the *Medico-Chirurgical Transactions*, I have thought it best to lay before the Medico-Chirurgical Society a more detailed account of the condition of the semicircular canals, accompanied by drawings.

Observations. There can be no doubt that the cause of deafness in the patient from whom the ears were taken was the deficiency of the semicircular canals, but it is interesting to notice the thickened condition of the mucous membrane of the tympanic cavity, and the

presence of the purulent matter. From the dissections I have made during the last seven or eight years, which amount at the present time to *nine hundred and eleven*, it is quite apparent that the most frequent cause of deafness is a morbid condition of the tympanic mucous membrane. In some instances there are bands, connecting various parts of the tympanic cavity together, and preventing the natural motions of the ossicula and membrana tympani; in others the cavity is nearly filled by the thickened membrane, and very often there are large quantities of thick viscid matter, which I have every reason to believe may remain for many years if not affected by medicinal agents. A great number of cases of this kind originate in scrofulous inflammation. It is also interesting to remark how rarely the Eustachian tube is affected. I hope ere long to lay before the medical profession the results of some of my later investigations into the nature and treatment of diseases of the ear.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF WILLIAM SANDS COX, ESQ.

By Peter Hinckes Bird, one of the Resident Medical Officers.

(*Continued from page* 100.)

Case XXIII.

LUPUS OF THE FACE.

Thomas Moss, aged 18, tinman, of strumous diathesis, admitted as out-patient at the Queen's Hospital, April 24, 1846, under the care of Mr. William Sands Cox. He states that about three years ago he first observed two or three small pimples on the nostril of the left side of the nose, and one also appeared about the same time on the right side; they burst and formed scabs, and ever since the disease has gradually increased and involved the other parts; has had swelling of the submaxillary and cervical glands for some time; has always enjoyed good health; his parents are both alive and in good health, as are also his brothers and sisters; is rather subject to cough; has spit blood.

Present state.—There is a large patch of ulceration involving both alæ of the nose and septum, which are more or less eaten away, on the left side to a greater extent than on the right; the upper lip is much thickened, and is attacked with this ulceration; he has also a large patch on the left cheek, larger in extent than the bottom of a wine-glass, and also one under the chin, which is partly covered by desquamations of the cuticle. The ulceration is superficial and of a dusky red colour, and secretes a thin pus which dries in some places and forms scabs; the edges of the ulceration are tuberculated and the interior presents several small depressions filled with matter. He has also an abscess of a strumous nature on the back of the hand which has been three years in coming; it discharges a thin flaky pus; he has three glandular swellings of large size situated under the ramus of the jaw on the left side; bowels open; appetite good; tongue clean; complains of slight cough; the ulcerations in the face feel hot; has sometimes a little pain in them, but is generally free from it.

R. Infusi Cascarillæ, oz. iss., ter die. To have the Ung. Zinci on lint applied to the wounds, and a poultice applied to the abscess.

30th. Rather better; the parts do not feel so hot; in no pain. To have the abscess strapped with iodide of lead plaster.

May 5th. The ulceration is not spreading but is rather smaller; there is a slight discharge from some parts of the surface.

16th. Better in all respects; ulceration healing and is certainly less; abscess of the hand smaller; health improved.

22nd. The ulceration is healing and getting into a much smaller compass; it has not broken out in any fresh place; abscess of hand decreasing in size; health good.

27th. Doing well; the ulcerations are getting smaller leaving behind them a livid red cicatrix; the patch on the upper lip is quite healed over.

July 8th. Much the same; the large patch on the cheek is healing rapidly; he had a few days ago a violent attack of hæmoptysis accompanied with much cough; has got thinner lately; sweats much in the morning; flushes at times; pulse 90.

R. Syr. Papav. Alb., Oxym. Scillæ, utrq. oz. ss.; Inf. Rosæ. Co., ad oz. vj. M. Sumat oz. j. ter die.

July 20th. Rather better; cough easier; expectorates a good deal of greenish sputa; had a slight return of the spitting of blood this morning.

30th. Better; cough easier; the patch on the cheek is nearly healed over; that on the nose is quite so; his face is much disfigured by the livid-red cicatrices left behind.

Aug. 27th. He has not made his appearance at the hospital lately, so that we may infer that he is satisfied with his present state.

Lupus belongs to the order tubercula. Rayer describes two varieties of this disease, namely, lupus exedens, and lupus non-exedens, to which M. Biett adds a third,—lupus with hypertrophy. The first of these ulcerates from the surface inwards and leaves deep excavations; the second spreads and ulcerates horizontally; the third rarely ulcerates at all. The two latter are tubercular diseases, and are comparatively rare in this country.

The lupus exedens is a frightful disease, difficult of cure, and when cured leaving behind it more or less deformity. Mr. Plumbe* doubts whether this form is strictly of tubercular origin. It is in fact a chronic cutaneous inflammation of a peculiar character, at once indolent and irritable, but often for a time devoid of pain, of a livid colour, commencing generally in a small portion of the alæ of the nose, or the circumference of the nostril, and speedily tending to phagedenic ulceration; it commonly extends to the

* On Diseases of the Skin, Ed. 3rd.

upper lip, and in this case the ruthless invader had attacked the chin and cheeks.

Of the causes of this disease little is known. Young persons of a scrofulous habit appear more subject to this frightful disease than others. It has, however, been seen to attack persons apparently of the soundest constitution; in this case the patient was without doubt afflicted with tubercular phthisis. It is common in young and previously healthy women from the age of 16 to 30. It is not contagious. This disease is often treated with escharotic applications, such as the chloride of zinc, arsenious acid, &c. &c.; but this case got well under the simple application of the ointment of the oxide of zinc, with a tonic medicine.

This disease has often been most inexcusably confounded with syphilis, and has been aggravated by mercurial salivation. In syphilis there can always be traced, at least a concatenation of secondary symptoms previously developed, and this disease usually commencing from within, the cartilages suffering first; and the ulceration has a specific character. In lupus, on the contrary, the disease appears in persons who have generally enjoyed good health, and in whom neither primary nor secondary symptoms have made their appearance; and it appears as a livid red, not a copper-coloured eruption.

Case XXIV.

PARTIAL LUXATION OF THE ANKLE-JOINT.

Thomas Porton, aged 23, carman, admitted on the evening of August 3rd, 1846. He states that about half an hour previously he slipped off the foot-path into the gutter; he fell with his left foot bent under him; he heard something snap; it caused him great pain, so that he could not walk; he was brought to the Hospital in a car.

On admittance, it was found on examination, that the patient had a partial dislocation of the ankle inwards, the lower head of the tibia being thrown inwards, the internal malleolus forming a more considerable prominence than natural; no fracture of the fibula was discovered; there was considerable swelling in the neighbourhood of the ankle; the outer edge of the foot was slightly everted. The dislocation was easily reduced; after the reduction the pain was lessened; he states that his bowels are rather confined.

Appl. Hirud. viij. partis affectæ. To be followed by a poultice and warm fomentations.

Habt. Mist. Purgant. Pil. cum Calomel., ij. hora somni sumend.

Aug. 4th. Slept indifferently last night on account of the pain; not so much swelling; less pain; tongue coated; pulse 86, strong; bowels open. Continue fomentations.

5th. Slept better last night; appetite indifferent; tongue coated.

6th. Did not sleep so well last night; complains of constant pain from the ankle to the knee.

7th. Feels better in every respect; can move the ankle freely. To have a splint applied, the part to be kept damp by cold lotions.

9th. Better; can walk pretty well.

13th. Discharged cured.

Dislocations of the ankle are generally attended with fracture of the fibula in its lower third; but in this case no fracture was present, he rapidly got well, and was able to walk in less than a fortnight.

WEST NORFOLK AND LYNN HOSPITAL.

COMPLICATED SURGICAL CASES UNDER THE CARE OF CHARLES COTTON, ESQ.

(*Continued from page* 41.)

COMPOUND COMMINUTED FRACTURE OF THE HUMERUS; LESION OF VESSELS: RECOVERY.

Robert Gant, railway labourer, aged 20 years, admitted May 9th, 1846, under the care of Mr. Cotton. Had fallen across the tram-road of a neighbouring railway in the course of construction, and received considerable injury from a loaded truck having passed over his right arm. The accident happened two hours before.

On examination the arm was found much contused and swollen, just above its centre, and ficrid blood oozed freely from an irregularly lacerated wound on the outer side, extending to the bone, which was comminuted and fissured. *No pulsation below the seat of injury.*

Relying upon the age and the robust and healthy appearance of the man, it was determined in consultation to attempt the saving of the limb. The arm was therefore placed by the side upon a soft pillow, guarded with oil-silk. The fragments of bone, (in all *five*,) constituting about three inches of the shaft, were removed through the wound, one portion requiring to be freed from its muscular attachments by the scalpel. A long projecting point from the upper fractured end of the humerus, reaching to the lower, and overlapping it, was allowed to remain. A dossil of lint was applied to the wound, the injured parts ordered to be exposed, to check the oozing of blood, and a moderate warmth to be kept up about the hand and forearm. Low diet.

10th. Temperature of the arm natural.

11th. Bowels have not acted; is feverish, and fearful lest he should lose his arm. Ordered a saline aperient.

12th. Bowels moved twice; irritative fever very high; several vesicles filled with serum around the seat of injury; the hand is comfortably warm, although sensation is imperfect. Liq. Ammon. Acet., dr. ij.; Spir. Æth. Nitr., m. xx.; Vini Antim. Tart., dr. ss.; Tinct. Hyosc., m. x.; ex Aqua, quartis horis.

15th. Considerable phlegmonoid inflammation and swelling of the arm and elbow. A quantity of pus was set at liberty by enlarging the original wound, and making a depending outlet below the elbow. Pergat.

17th. Arm looking better; angry appearance subsiding; discharging freely. Middle diet and porter.

From this time to August 14th the case went on well, requiring but little interference; the wound at the elbow had healed, leaving the joint œdematous and swollen; a sero-purulent discharge continued from the upper wound, which remained open, filled with gelatinous-like granulations, and the skin around red. There is an abundant deposition of bony callus around the

fracture; *no pulse at the wrist.* A long splint was adapted to the arm, and the patient allowed to leave his bed.

18th. Much headache and feverishness; arm uneasy; splint removed. Low diet and house medicine.

19th. Erysipelas supervened, involving the whole arm and shoulder. Limb to be exposed. Potassæ Nitratis, Potassæ Bicarb., utrq., gr. x.; Vini. Antim. Tart. m. xx.; e Mucil. Acaciæ, tertiis vel quartis horis.

24th. Erysipelas subsiding; skin efflorescing; a serous discharge escapes from the wound and two or three small abscesses have formed in the adjoining soft parts.

September 2nd. A pasteboard splint applied; a slight pulsation as if a capillary thrill, thought to be detected at the wrist. A portion of bone has exfoliated.

20th. Again severely attacked with erysipelas, extending over the arm, shoulder, and chest. Exposure. Low diet and nitre mixture as before.

28th. Erysipelas disappearing. A small piece of bone has come away.

October 24th. The force of the collateral circulation quite perceptible at the wrist; can slightly flex the fingers but cannot raise the arm without assistance. There still continues a discharging sinus, from which an additional portion of bone has exfoliated; the surrounding soft parts are becoming more healthy looking, although still œdematous and swollen, particularly about the elbow. Apply light pressure by means of a bandage, and make him an out-patient.

December 26th. Regaining a useful, though somewhat shortened arm; can raise it without assistance; flexion at the elbow still much limited; can grasp pretty strongly with the hand; pulse established at the wrist. Ordered to use the limb, and to be discharged, cured.

(*To be continued.*)

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, MARCH 10, 1847.

The process of inhaling æther for the avoidance of pain during surgical operations, has taken so fast hold of almost every professional man in this country, that it behoves the journalist to look to the subject, and from his focus of information scatter a few useful remarks and cautions on the employment of this new process.

How often has accusation been made by enthusiasts of various descriptions against members of our profession generally, for their incredulity and prejudices in respect to the several delusions with which this age of quackery teems. Yet was censure never less justly applied. The profession are commonly eager enough to embrace any new proposal, and give a laudatory report of its application; too often indeed, at first, without due regard to its effects, or rather perhaps its defects, whenever there is reason and probability in its favour. In the instance of this novel plan for diminishing human suffering, whatever may have been stated on other occasions, sufficient has occurred to redeem the character of the profession, and to prove the readiness of its members to adopt any new suggestion, when supported by facts, and by the slightest colouring of reason.

Whatever hints may previously have been given upon this new application of æthereal inhalation, we are undoubtedly indebted to our Transatlantic brethren for effectively starting it in practice, "*Palmam qui meruit ferat.*" Not he who tamely offers a suggestion, but he who with energy and spirit forces his ideas upon the public, and starts them into practical life and activity, deserves the credit of an invention. In the short space of a few weeks the æthereal inhalation has been tried in our own country in many hundreds of instances; in all parts of the provinces, as well as in the great centres, the metropolis of each division of the kingdom; employed for avoiding pain, not only in the slighter matter of teeth-extraction, but in all cases of the great amputations and other capital operations, and even to strangulated hernia, extirpation of the eyes, ovariotomy, the Cæsarean section, &c.

In a small proportion only of these cases, of whatever description, has the process failed to take effect; and although to a few patients it has proved inconvenient, to none is it reported to have proved fatal, and very little has yet been written upon the cases to which the new measure is inapplicable. Such is the usual course of a novel plan launched upon the wide ocean of practice under popular favour. All appears fair for a prosperous voyage; but it is a voyage of discovery; the quick-sands and dangers are at a distance, and we must wait the navigator's return ere we can learn the whole issue of the undertaking.

The inhaling for the production of narcotic or intoxicating effects is not new, but the extensive adoption of it, in the manner we are considering, may still render a new term convenient, and even necessary. The instrument employed, of whatever construction, has received the appellation of "the Letheon," and from this root is readily to be derived all the terms required. The phenomena which a *letheonized* patient presents, are very similar to those of intoxication, varying in degree from hilarity to half consciousness, complete narcotism, total insensibility to external impressions, failure of pulse, syncope,—may we not add death.* The most striking, if not

* Since the preceding observations were written, a notice of the occurrence of a fatal case, which will be found narrated in another column, has been received;

the peculiar circumstance, is the rapidity with which the effect is produced, the shortness of its duration, and its equally rapid subsidence. The brain is the organ acted upon, and in proportion as external impressions are shut out, internal ideas seem to be generated. A letheonized patient is a sort of Ryp Van Winkle; he dreams away twenty years of his past life in a minute, but with equal surprise, and unlike his predecessor, on awaking to the world again, finds it much as he left it. These psychological phenomena will doubtless furnish a fine study for the physiologist and the metaphysician.

Nothing is more remarkable than what every one who sees half-a-dozen letheonized patients will be sure to witness,—a state of half-consciousness, with eyelids open, a congested countenance, a frightened stare. The patient is sensible of persons present, and talking, and because he is still in a degree sensible, protests against the operation, whilst it is actually being performed; and on the *letheonic* influence subsiding, which it does in two or three minutes, he reports the trial a failure, and waits the operation, which is already completed without his being conscious of it. How are such opposite states of the sensorium compatible? May we conjecture that the succession of ideas is so rapid, that they seem coincident or synchronous, though really successive and alternating?

But we pass to the less speculative part of the subject, as more immediately applicable to our purpose, and we urge our provincial brethren to emulate those of the metropolis in helping to elucidate the use of the Letheon, and particularly to giving us an account of any unfavourable result of the trial,—any cases that may seem unsuited to it. We can scarcely persuade ourselves that the pain naturally attendant upon all mutilating operations upon the human frame, is to be quite annihilated by this discovery, although nothing could be more congenial to the wishes of both the patient and the operator. It will probably turn out that there are cases to which the measure is wholly unsuited, wholly improper. When next "we dip pen" in æthereal fluid, we shall endeavour to write a few cautions, and give a guarded prognosis, as to past or prospective events; meantime, let the incautious Letheonizer beware, remembering that "all is not gold that glitters."

Reviews.

The London and Provincial Medical Directory. 1847. London. pp. 238 and 362.

In an undertaking of this description, especially on the occasion of its first publication, the occurrence of errors is unavoidable. Our provincial friends will, we fear, find these to be numerous and grave, as, judging from the examination we have made, in referring to names well known in our larger towns, and not unknown also in the great metropolis itself, scarcely that care which is requisite would seem to have been employed. Certain of these errors are, no doubt, to be attributed to gentlemen applied to by circulars, having neglected to forward the information asked for; others to the unfortunate scrawls in which too many of our brethren are wont to render themselves unintelligible. But what shall we say for sundry errors of omission and commission, in cases where the information sought for has actually been supplied? Possibly a portion of this may have been thought too trivial for insertion; and had a line of exclusion been drawn, by adherence to which equal justice might have been dealt out to all, in the giving or withholding of titles, appointments, and other claims to consideration, there would have been little cause for complaint; but when we find to some gentlemen ascribed, in addition to genuine qualifications, obscure appointments of which nobody ever heard, or the publication of some brief epistle which nobody ever read,—

"Behold Dalhousie, great God of War!
"Lieutenant-Colonel to the Earl of Mar!"

while from others, all mention of long services as medical officers, whether civil or military, is withheld (due information fsuch services having been supplied,) we are at a loss to devise a palpable excuse for the omissions.

With the question which is attempted to be raised, as to the degree of estimation in which the license of the Apothecaries' Society, and the diploma of the London College of Surgeons, are respectively to be held, we do not feel disposed here to intromit; but we may observe that we find the term 'General Practitioner,' by which it is professedly intended to designate the possessor of the former, sometimes misapplied to those who hold only the diploma of the latter.

But with all this, the publication is one which is calculated to be of great utility. Even in its present imperfect state it affords much information which can nowhere else be met with; and if the errors are duly corrected, which can only be fully and effectually accomplished by individual medical practitioners communicating the requisite information, the edition of another year will prove most acceptable to the entire medical profession.

A Tabular View of the Physical Signs and Diagnosis of the Diseases of the Lungs; with a Synopsis of the Signs which occur in each Disease. By James Turnbull, M.D., Physician to the Liverpool Northern Hospital. London.

We notice this work simply with the view of directing the attention of our readers to a very useful summary of the diagnostic symptoms and characters of diseases of the lungs. The table is folded in a royal octavo

size, and bound up with the accompanying synopsis, with which it admits of convenient consultation and comparison; but it may be also detached and mounted for setting in a frame, and hung up in the consulting room for more ready inspection and reference, as called for. In either way it affords at a glance much valuable information, which it would require the pages of a goodly octavo to set forth.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

January 2nd, 1847.

FREDERICK RYLAND, Esq., in the Chair.

RUPTURE OF THE LEFT VENTRICLE OF THE HEART.

Dr. Fletcher presented a specimen of rupture of the left ventricle of the heart, and read the following letter which he had received from Mr. Savage, of West Bromwich, who had kindly forwarded the specimen to be exhibited to the Society :—

"Dear Sir,—I send you a report of the case connected with the specimen of rupture of the heart I gave you to-day.

"Samuel Allden, of Birmingham, was brought to my surgery about 7 a.m., on Monday last. He was quite dead. It appears he left Birmingham about 6 a.m. of the same day to walk to West Bromwich, to see his son, who resides here. He was overtaken by a coal cart about mid-distance between Birmingham and this place. He asked the man to allow him to ride with him to West Bromwich; he complied with his request. The deceased got into the cart, and sat with the driver on a board put across the cart from side to side. They conversed together on the way cheerfully; the deceased made no complaint whatever. On getting within half a mile of this place the deceased suddenly fell over into the body of the cart, never spoke after, gave one or two gasps, and appeared dead. The man drove at once to my surgery, where on seeing him I found him dead. I have heard from his son that his habits for the last thirty years have been very intemperate.

"*Post-mortem* eight hours after death. He was of nervo-lymphatic temperament; rather full habit of body; no appearance of external injury. On opening the chest and abdomen the cellular tissue was somewhat loaded with fat. We found the pericardium very much distended, and on opening it discovered it to be filled with black blood, both fluid and coagulated, at least amounting to thirty ounces; the left ventricle of the heart we found ruptured; the lungs healthy; no adhesions. The mucous coat of the stomach was inflamed and softened; the liver enlarged, otherwise healthy; the intestines healthy; the bladder and kidneys normal. I did not open the head. There was, in fact, almost the entire absence of any disease except the rupture of the heart."

The heart was enlarged to about half above its natural size, which consisted of a general and equal dilatation of all its cavities, and a corresponding hypertrophy of their parietes. The rupture, situated on the inferior portion of the anterior surface of the left ventricle, consisted of an external laceration about an inch and a half long, extending from about an inch from the septum upwards and outwards, at the inner terminus of which was a round aperture about the size of a large swan quill, which communicated with the interior of the cavity of the left ventricle. In the interior was another laceration or extended ulceration, by which one of the columnæ carneæ had been divided, lined with lymph, and crossing the direction of the external laceration, so as to form a St. Andrew's Cross. The inferior portion of the left ventricle was very much softened. The mitral valves were thickened at their edges; the aortic valves natural. The aorta was dilated, its lining membrane studded with a few patches of atheroma and one of ossific deposit. The apertures of the coronary arteries were dilated, and these arteries themselves much dilated and ossified, particularly the branch of the left coronary running down to the softened and ruptured portion of the left ventricle. The heart was very much coated with fat.

Microscopic examination with a Powell's microscope of Dr. James Russell's, in which he kindly assisted:—In a portion of muscular structure taken from the upper part of the ventricle, where the structure seemed healthy, the muscular fibres were healthy, and the striæ complete; a few fat-globules floating around the edge. In a portion taken from the lower part of the ventricle, where the structure of the ventricle was softened, the fibres of the muscular structure appeared under the microscope smaller than natural, and the striæ in most parts totally absent; in some few portions the striæ were slightly to be perceived when out of focus, so that it is presumed, quite the superficial surface of the muscular fibre was brought into view; there were numerous fat-globules. In a portion taken from the ruptured part of the heart, the muscular fibres were very indistinct, and the striæ, as in the second portion examined, only seen in some parts feebly, and when out of focus; there was abundance of fat-globules.

Dr. Fletcher said that this appeared to be a case of rupture resulting from ossification of the coronary arteries, having caused softening and disorganization of the muscular structure of the left ventricle; the internal laceration must have been caused first, and whether this commenced by laceration or ulceration it is now impossible to determine, but the deposit of lymph shews it to have been of some standing.

The microscopic examination is interesting, as shewing the alteration of the structure of the muscular fibre to correspond with the ruptured and softened portion of the parietes of the left ventricle.

ABNORMAL ATTACHMENT OF THE FUNIS.

Dr. Fletcher exhibited a placenta, membranes, and funis, which had been brought for exhibition to the Society, by Mr. Wright, who gave the following description of the case :—

After delivery the membranes came away separated from the placenta and attached to the cord, and contained

so much clotted blood that it appeared as if the placenta itself was come away, which, on examining the cord and membranes was found not to be the case. On examination per vaginam, the placenta was found within the os uteri, and brought away in the hand, and no trace of attachment of the cord to any part of its surface could be discovered.

OPERATIONS PERFORMED UNDER THE INFLUENCE OF ÆTHER.

By William Philpot Brookes, M.D., M.R.C.S., Surgeon to the General Hospital and Dispensary, Cheltenham.

Since reporting my former case, I have successfully performed the following operations under the effects of the inhalation of æther:—

Ann Weston, aged 69, living at No. 1, Burton Street, had been suffering for the last twelve months with fistula in ano, and had been during the whole of the time confined to her bed. She was of a very nervous debilitated habit, and would not give her consent to the performance of an operation, but upon hearing of my former painless case, she sent for me, and desired to have the operation performed. On examination I found the whole verge of the anus in a state of ulceration, accompanied with great pain. The probe discovered a fistulous sore, extending full four inches into the rectum, the walls of it of some thickness. Having put her in train for performing the operation, it was done in two days afterwards. The patient was laid on her back, with the head elevated, (so as to have no difficulty with the æther,) the buttocks raised, knees drawn up, and held apart. I then passed up my finger, inserted the director, when the inhalation of the æther commenced, (with merely a bladder and elastic tube,) and she was in a complete state of unconsciousness in two minutes. The bistoury was then introduced, and the fistula divided in its whole length without the patient showing the least symptoms of pain or uneasiness. When it was over I asked her if she had quite made up her mind to have the operation performed. She said, "Yes, please go on with it as quickly as possible." When told it was over she uttered great surprise. At this operation the following gentlemen were present:—Drs. Wright, Bagnall, Bree, Smith; Messrs. Eves, Ocrell, Peart, Alix, Tibbs, Rowe, Norman, and Churches, and all agreed and expressed themselves perfectly satisfied with the result.

The next case was that of Ruth Monk, aged 21, who wished to have the last molar tooth extracted under the æthereal influence. She is of full, plethoric, and excitable habit. In one minute and a half she was in a state of unconsciousness from the æther and became quite unmanageable, her face flushed, and she required two persons to hold her. I lanced the gum without any sign of pain, and she recovered her sensibility immediately. As she was very anxious to have the tooth extracted, she again inhaled it, and when under its influence some excitement returned, and on drawing the tooth with the claw she cried out, "Oh!" but on coming to herself stated she had had no pain; and having had nine out before, she could judge of its effects, and said, "I will never loose another tooth except I am prepared in a similar manner so as to have no pain."

February 1st, 1847. The following cases were operated on to-day, in the presence of fifteen gentlemen, most of them members of the profession:—

John Coombes, aged 56, a labourer on the roads, residing at Charlton, of a strong plethoric habit of body. Whilst at work he met with an accident (three weeks back,) to the middle finger of the right hand; mortification took place, and the first joint sloughed away; still he would not consent to the loss of the finger, and the disease extended to the metacarpal bone. Having heard he could have it taken off without suffering any pain he applied this morning to have the operation performed. The æther was inhaled and the man under its effects in six minutes. He remained so for five more, and the finger was taken off by a V shaped incision, opening the metacarpal bone half way down with Liston's bone nippers. The patient did not shew the slightest sign of pain, and stated that he heard the bone cut, but positively asserted he felt no uneasiness of any kind, and grumbled much at the suffering we gave him when taking up the arteries afterwards. I allowed this case to remain for half an hour before I dressed it, as I am inclined to think secondary hæmorrhage will often occur after the effects of the æther have passed away; reaction does not until then become perfectly established. Small arteries often escape untied if we dress immediately, and union will not take place so well on account of extravasation of blood. The pulse in this case was before the operation 84, and during the æthereal process it varied from 60 to 70.

William Guy, aged 21, residing at No. 44, Duke Street, of a pale exsanguineous habit of body; has had phymosis from syphilis for several months, and wishing to have the glans penis liberated, submitted to the operation. The æther was inhaled, and produced its effects in three minutes. The skin was then divided down to the end of the glans without any sign of pain, and he states he did not feel anything of it. Pulse when in the æthereal state was 75, and soft, and before that time 90.

A servant, aged 30, had four stumps extracted without giving her the slightest pain, by Mr. S. Tibbs, surgeon-dentist of this town. The æther was inhaled from a modification of Dr. Snow's apparatus, and she got under its influence in less than two minutes, and remained so nearly five. Positively states she felt nothing.

Lot Organ, aged 36, residing in Grove Street, of spare habit of body, has had a disease of the left elbow-joint for the last year or two, and would not consent to its being amputated before, but the general health becoming injured, he now consented. The æther was given with Snow's apparatus, and after its inhalation for nearly four minutes, he appeared quite unconscious; the healthy arm dropped involuntarily to the side when

raised, eyelids closed, and all the usual signs of insensibility to pain. The circular incision was now made through the skin, and he cried out most lustily, and continued doing so through the whole stage of the operation. After it was all over he stated he felt the first cut, and also the bone sawed, but he was in a dream, and smoking a pipe, which some one tried to take from him.

I can only view this case as a failure, and I think it right alike to report all, whether failures or not. The other cases were decidedly successful. I may state in the above operation the mouth-piece did not nicely fit the mouth, and he appeared to have inhaled fresh air by its side.

Albion House, Cheltenham,
February, 1847.

REMOVAL OF THE GREAT TOE AND PART OF THE METATARSAL BONE, UNDER THE INFLUENCE OF ÆTHER.

By T. Herefrt Barker, M.B., M.R.C.S.

Emma Rawlins, aged 23, of Cople, near Bedford, had been labouring under strumous disease of the great toe, involving the phalanges and part of the metatarsal bone, during the last five years, and was anxious to have the diseased parts removed by operation.

Desirous of giving her the benefit of inhaling the vapour of æther, I procured the apparatus constructed under the directions of Dr. Boott and Mr. James Robinson, and sold by Mr. Hooper, of Pall Mall, London, and yesterday removed the parts in the following manner, with the kind assistance of Mr. Hurst, and in the presence of Messrs. C. W. Hyne, W. Bailey, Anthony, Birch, Cox, and Ravenscroft:—

Having succeeded in about four minutes in getting her thoroughly under the influence of the vapour, a flap of good size was made, with a scalpel on the inner side of the foot, the metatarsal bone being laid bare beyond the extent of the disease. A strong bistoury was then passed through the space between the metatarsal bones of the first and second toe, in close contact with the former, and brought out anteriorly; the flexor and extensor tendons were divided, and the metatarsal bone nipped through with Liston's forceps. The exposed surfaces were sponged, and the flap secured by three points of interrupted suture.

During the operation, which lasted but a short time, the supply of vapour was cut off by means of the stop-cock; she did not in the least shrink from the knife, nor did she manifest in any way the slightest sign or expression of pain. On regaining her consciousness, she inquired when the operation would commence, and on being told that it was all over, stated that she had been asleep and dreaming.

The testimony of so many operators has already been recorded of the efficacy of the inhaled æther, in completely deadening the sensibility of the system, during severe and protracted operations, that there cannot be a doubt that this is one of the *greatest* discoveries of the age, productive as has been that age of great discoveries.

I thought it desirable that my patient should be previously tutored in the process of inhaling, and for that purpose induced her to inhale the æther the day before the operation, which she did, to the entire satisfaction of both of us. This appears to be a matter of some importance, and likely to contribute to the success of the process, for there are several precautions which are better thus explained beforehand, and the patient will be less likely to be affected by timidity at the time of the operation.

The points which appear to require particular attention are:—

1. To tutor the patient beforehand in the process of inhaling.

2. To give charge of the inhaling apparatus to a trustworthy assistant, who should keep the mouth-pad in firm contact with the lips.

3. To allow two or three inspirations to be made *before* removing the small stopper, and applying the nasal spring, otherwise the full volume of the vapour will be likely to excite coughing and a sense of suffocation.

4. To cut off the supply of vapour for a time, by turning the stop-cock and removing the nasal nipper, when deep insensibility has been produced.

The *morbid* effects of the inhalation of æther have yet to be made out, and good service will be rendered to the profession and humanity, by any one who will investigate the precise effects of this powerful agent, when administered in cases complicated with pulmonary, cardiac, or cerebral mischief. Some affections of the heart, and a strong predisposition to cerebral disease, will probably be found to be the morbid conditions more particularly contra-indicating its employment.

Bedford, February 16, 1847.

REMOVAL OF THE NAIL FROM THE GREAT TOE, UNDER THE INFLUENCE OF THE VAPOUR OF SULPHURIC ÆTHER.

On Monday, January 18th, Mr. Rudall, surgeon, of Sheepwash, North Devon, in the presence of J. G. Maxwell, Esq., performed the operation of removal of the great toe nail with part of the toe, on the person of an athletic farm-labourer, aged 22 years, the patient being put under the influence of the æther vapour. The result in the most satisfactory manner, confirmed all that has been reported of this extraordinary means of subduing pain in the performance of surgical operations. The vapour was administered by means of an apparatus extemporaneously constructed, and consisted of a large-sized bullock's bladder, to which was connected a tube of half an inch in calibre, and two and a half inches in length, this was attached to a bulb capable of containing about eight ounces of fluid; continued from this was a tube seven inches in length, and a quarter of an inch in calibre. The æther (six drachms,) being put into the bladder, which was afterwards inflated, and the tube being introduced into the patient's mouth, the inhalation was commenced. In rather less than one minute perfect insensibility was produced, a gentle tremulous motion of the lips,

and a slight rising and extension of the left arm, were the only actions observable after the first few inhalations. The operation was now begun and completed in two minutes more. Thus, from the commencement of the inhalation to the completion of the operation only three minutes elapsed. The pulse, which at first beat 72 strokes in a minute, rose during the administration of the vapour to 120 strokes. At the end of the inhalation it became intermitting and after a short period was scarcely perceptible. A small quantity of spirit and water was administered. After the lapse of five minutes sensibility appeared to be returning, and he muttered something in which he made use of the word "mother." He afterwards said he thought he had been walking with her. It was fifteen minutes before he became sensible of surrounding objects. He knew nothing of the operation that had been peformed on him,—said that he had been asleep,—that he had experienced no unpleasant sensations,—and that he wished to go to sleep again. He says that he felt drowsy for two hours.

The patient never had an unfavourable symptom; the only dressing used was cold water; and at the end of a fortnight he resumed his thick boots and returned to his labour.

OPERATION FOR LITHOTOMY PERFORMED UNDER THE INFLUENCE OF ÆTHER: DEATH.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

At a time when the attention of both the medical profession and the public is being called to the influence of æthereal vapour, as an agent in diminishing pain during surgical operations, you may probably consider the accompanying case of sufficient interest to be admitted into your columns.

I am, Sir,

Yours obediently,

ROGER S. NUNN,

Surgeon to the Colchester and Essex Hospital.

Colchester, February 26, 1847.

On Friday, the 12th inst., I operated upon Thomas Herbert, aged 52, the subject of stone in the bladder, in the presence of most of the medical gentlemen of the town and neighbourhood. The æther was exhibited by my colleague, Dr. Williams, who considered the patient to be sufficiently under its influence after inhaling it seven or eight minutes, at the end of which time I commenced the operation. There was neither difficulty nor loss of time in cutting into the bladder; but having done that, some little delay occurred in grasping the stone, which was small, very flat, and lying in the posterior part of the bladder. The delay was also increased by the extremely relaxed state of the bladder itself, which seemed to fall in folds upon the forceps, and to cover the stone. The time occupied from the commencement of the operation to the period when the man was unbound, was ten minutes, during which the æther was administered at intervals. The patient was placed fully under its influence, and the breathing first became heavy, and ultimately stertorous. He recovered, however, from its effects after a short time, and continued in a quiet passive state, but without decided re-action, for twenty-four hours.

At this period he had a severe chill, which lasted for nearly twenty minutes. Mr. Taylor (the house-surgeon,) immediately gave him two ounces of brandy, with an equal quantity of water, after which the patient remained in a dozing state till eight o'clock p.m., when the house-surgeon considered it necessary to send for me, as a state of complete prostration or collapse had ensued. I ordered small quantities of brandy and water, (half brandy,) with arrow-root, at intervals, wrapped him in hot blankets, placed bottles of hot water in the bed, &c. This treatment was kept up till nine o'clock the following morning, when ammonia was given, alternately with the afore-mentioned stimulants. The patient seemed incoherent from eight o'clock p.m. of Saturday, till nine a.m. of the following day, when symptoms of slight re-action appeared.

At a consultation of the medical staff which was held at this time, it was determined that the same treatment should be continued, (modified according to circumstances,) and that in addition, a stimulating injection should be exhibited. The effect of the injection was to increase slightly the frequency of the heart's pulsation, but without exciting his nervous energies. From this period he gradually sank, and died at five o'clock, p.m., being sensible to the last.

I should here mention, that the small vessels which are necessarily divided in making the first incision, shewed much inclination to bleed, owing, I imagine, to their want of contractile power; I therefore, to prevent any unnecessary hæmorrhage, secured them immediately after the patient was put to bed, so that he did not lose much blood.

Post-mortem, sixty-seven hours after death. Membranous congestion of the brain, but no effusion; brain firm; lungs permeable throughout, anteriorly exsanguineous, posteriorly engorged; heart flaccid, of a natural size, and nearly empty; left kidney pale, the right slightly congested; the bladder and the adjoining parts presented the usual aspects after an operation.

(Signed,) E. WILLIAMS, M.D.,
ALDERMAN PARTRIDGE,
WILLIAM WAYLEN,
ROGER S. NUNN,
JOHN CHURCHILL,
CHARLES E. BLAIR,
WALTER JOHNSON,
THOMAS TAYLOR.

I would mention that the blood throughout the whole vascular system, was in a perfectly fluid state.

It is not my intention or inclination to attribute the loss of my patient wholly to the influence of the æther which was administered in this case, nor hastily to decry its use under all circumstances connected with surgical operations; but still, I feel called upon to bring before the notice of my medical brethren, the effect which resulted from its exhibition in this instance, that the profession may judge from the recital of an unsuccessful case,

how far it may be considered safe to employ æther generally as a means of preventing the pain, otherwise inseparable, from physical lesion. The suffused eye, livid lips, and stertorous breathing, accompanied first by convulsive struggles, and next by a sudden cessation of all motion, are often indications of the effects of the vapour, and these were not altogether absent in the present instance. Still, I felt myself justified in employing it, from the published accounts of many successful cases, and the sanction of my colleagues and numerous friends around me.

In prosecuting the operation, there was nothing peculiar to attract my attention, or to lead me to consider the patient's physical condition differed from that of those on whom I had before operated, until I had reached the bladder, when I cannot but attribute the difficulty in seizing the stone to the apparently collapsed state of that viscus, which had fallen in folds over the calculus, and so prevented its bring grasped by the forceps. I must not, however, omit to mention the fact, that the patient expressed no signs of suffering during the operation. Thus far, therefore, it may be said the æther fulfilled its intended office; but I think another question is involved—viz., whether the artificial means thus employed may not produce very serious depressing effects on the nervous system, depriving a patient of that re-active power so necessary to the reparative process? Has not a patient, after the administration of æther, a double shock to overcome,—that produced by the vapour, superadded to that of the operation itself? Does not the history of the *post-mortem* examination bear out the suspicion of the depressing influence of this inhalation?—positively, from the still fluid state of the blood, (although the body was not opened for sixty-seven hours after death,) and from the flaccid state of the heart,—negatively from the fact that the inspection detected no indications of violence done to the parts that could explain the rapid dissolution which ensued, and that there was no evidence of Nature having made the slightest effort towards local reparation. Pain is doubtless our great safeguard under ordinary circumstances; but for it we should hourly be running into danger, and I am inclined to believe that pain should be considered as a healthy indication, and an essential concomitant with surgical operations, and that it is amply compensated for by the effects it produces on the system as a natural incentive to reparative action.

I trust that the publication of this unsuccessful case may lead to the publicity of many others which have occurred, so that the profession may not be led away by the erroneous supposition that the prevention of pain is so vital a desideratum in operative surgery.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

ON THE UTRICULAR GLANDS OF THE UTERUS.

By Ernest Henri Weber.

After conception, the mucous lining of the uterus in woman softens and increases in thickness, and is then known as the "*membruna decidua.*" This change is the consequence of an increased development, both of the vascular membrane and of its epithelial investment.

The blood-vessels of this mucous tissue and the utricular glands increase in volume, and their interstices are occupied by elementary cells of new formation, many of which are destitute of nuclei.

In the human female, the uterine glands are enlarged after conception, and become tortuous and of an utricular form. As in the stomach, these glands are placed perpendicularly to the mucous surface, their orifice being towards the cavity of the organ. These orifices have been long known to exist in the deciduous membrane, to which they impart a cribriform aspect.

The uterine glands in the cat and bitch are only enlarged to any amount at the spot on which the placenta is implanted. They are at all times visible in these animals, independently of pregnancy, and consist of two species of glands; one small and simple, the other larger and branching. Both increase after conception; the former throughout their entire length; the others principally at that part which is nearest the intra-uterine orifice. At a certain point the trunk of the second order of glandules enlarges in the form of a pouch, which touches the parietes of the neighbouring blood-vessels, which convey the maternal blood. The villosities of the chorion which contain the ultimate ramifications of the umbilical vessels of the embryo, penetrate into the orifices of these uterine glands, and expanding in their cavities, form with them a single investment to the embryonic vessels. This membrane and its duplicatures surround the uterine blood-vessels, which, as has before been said, ramify on the interstices of the glands. After this union, the part of the membrane which was derived from the parietes of the uterine glands, becomes sensibly thinned by absorption.

Once formed, the placenta of the bitch is traversed by a dense network of tortuous capillary vessels, which conveys the maternal blood. Each of these capillary vessels is closely invested by a membrane, which contains a fine network of capillaries, derived from the vascular system of the embryo. It thus appears that the fœtal blood flows through a vascular network, over the surface of the larger vessels which contain the maternal blood. The two sets of vessels, however, do not communicate directly.

In the human female, the uterine glands appear to be increased in size over the whole surface of the uterus. Weber has not noticed that one part of their trunk dilates more than another, neither has he observed that the villosities of the chorion penetrate their cavities as in the bitch,—on the contrary, they are perfectly free. This difference in the formation of the placenta in the human female and in the bitch, is thought to be in some manner due to the formation of a "*decidua reflexa.*"

The human placenta then differs from that of the bitch:—1st. The dense network of vessels which conveys the maternal blood and traverses the entire placenta, consists in the human female of tubes of a much larger diameter, but with thinner walls. 2nd.

The other constituent part of the placenta, the villosities of the chorion, which convey the fine network of embryonic capillaries, form in the bitch, membranes and folds, and in the human species ramifications, which terminate in fine threads, interrupted here and there by nodular enlargements.

In the perfectly formed placenta, both in the human female and the bitch, the vessels which convey the maternal and fœtal blood are in intimate apposition. This is effected in the bitch, by the first named vessels being closely enveloped by the villosities of the chorion; but in woman the reverse is the case, the ramifications and the filaments of the villosities being surrounded by the enlarged vessels, which carry the maternal blood.

If it should eventually be demonstrated that the villosities of the chorion penetrate into the cavities of the uterine glands in the human female as in the bitch, the opinion above given will not be interfered with, for it will still be necessary to prove that the terminal filaments of the villosities are inserted, and as it were, soldered to the walls of the uterine glands. —*Archives d'Anatomie*, Dec., 1846.

PRACTICAL MEDICINE.

ON THE EFFECTS OF EMETICS IN YOUNG CHILDREN.

[The following remarks, by Dr. Beck, are worthy of attentive consideration, and we believe from frequent observations of the manner in which pulmonary diseases of infants are treated, that they are in no wise exaggerated :—]

1. As a general rule we need not be afraid of vomiting the youngest child, provided the means used are mild, such as ipecacuanha, &c. The mere act of vomiting is attended with no danger, while the remedial agency of an emetic is one of great power and value. Besides acting on the stomach, it extends its influence to the mucous membrane lining the pulmonary organs, promoting secretion in the first place, and then aiding in dislodging and ejecting morbid accumulations; accordingly, in pulmonary affections, there is nothing so efficacious.

2. The vomiting induced by the preparations of antimony ought to be resorted to with great caution in very young children, and should never be used except in those cases where a sedative effect is required, and can be borne with safety. Inflammatory excitement ought then always to be present to justify its use in a young child. Where the object is simply to evacuate the stomach, it ought never to be thought of. In such cases as croup and pneumonic inflammation, it may be justifiably and beneficially used. In these cases it will be found that the system can bear the sedative influence of the antimony much better than it can in the ordinary conditions of the system. Even here, however, care should be taken not to push the antimony too far, as dangerous collapse has been known sometimes to be the result.

3. The *continued use* of tartar emetic in young subjects cannot be too specially guarded against. It is in this way, probably, that it is so apt to prove injurious. A single dose, even though it vomits very freely, may be borne with comparative impunity, while the repetition of it may keep up nausea and intestinal irritation, so as to cause injurious prostration. This is very likely to happen in cases of a chronic character, like hooping-cough. Although mild emetics are among our best remedies in this disease, and where the subject is old enough, a single emetic of antimony is frequently exceedingly beneficial, yet the repeated use of antimonial emetics, as is too often the case, appears to me to be a great error in practice. It is not indicated by the nature of the symptoms, and violates a great rule which ought always to be observed in the management of chronic cases, and that is, not to break down unnecessarily the strength of the patient. Again, in ordinary catarrhal affections in children, a good deal of mischief is frequently done by the continued use of expectorant mixtures containing this active article.

4. As the effect of tartar emetic on the system cannot always be measured by its emetic operation, even in the adult, this fact ought to serve as a caution against the too common practice of giving repeated doses of it to produce vomiting in children, when they happen to be narcotized. While it fails to vomit, it may still operate as a poison to the system. In all cases of this kind, the proper method of treatment is, not to push the emetic, but to endeavour to restore the sensibility of the patient, and then sometimes vomiting comes on at once.

5. In using tartar emetic in children, especial regard should be had to their constitutions. In those naturally delicate, and especially where the scrofulous diathesis exists, it should never be used if it can be avoided. Prostration is much more apt to ensue in them, and where the article is persisted in for any length of time, is sure to do harm. It is in such constitutions, when labouring under hooping-cough, and where the use of this article has been too long continued, that the baneful effects of it are most strikingly observed.

6. It is perhaps hardly necessary to say, that if tartar emetic be an article of such danger, the younger the subject to whom it is given, the more likely is it to do harm. In children under a year, I should say, as a general rule, it ought never to be used. During that period, the powers of life are too feeble to bear so active a remedy, at the same time that all the beneficial effects of an emetic may be gained from the use of ipecacuanha, or even milder means.—*New York Journal of Medicine*, and *Dublin Medical Press*, Jan. 20, 1847.

SURGERY.

ERECTILE TUMOUR OF THE HEAD OF THE TIBIA; LIGATURE OF THE FEMORAL ARTERY : DEATH.

This instance of a disease which has only of late years attracted the attention it deserves, occurred at the Hotel Dieu of Toulouse.

The patient, a female, aged 25, experienced for the first time, about March, 1843, indistinct pains in the left leg. These pains were transient and did not impede the motions of the joint. About the middle of the year she fell from a chair and struck her limb, after which the disease from which she eventually died, declared itself more positively. A tumour was now

perceptible in the region of the head of the tibia, which was leeched by the surgeon in attendance, as may be imagined, without relief, but on the contrary it rapidly increased in size, until November, when it exhibited the following appearances:—At the upper part of the left leg immediately below the knee, an irregular tumour was perceived, consisting of two unequal elevations, hard and resisting, incompressible and not painful on pressure. Pulsations were also plainly perceptible isochronous with the arterial diastole; there was also a slight *bruit de soufflet*. Both the pulsations and bruit ceased on compression of the crural artery. The knee-joint and the poplitieal space were in their natural condition; the general health was good. The *diagnosis* was, erectile tumour of the head of the tibia.

The operation decided upon, namely, ligature of the crural artery, was performed in the January succeeding, the female being at the time five months pregnant. As soon as the ligature was applied, the pulsation in the tumour entirely ceased. The next day the tumour was considerably diminished in size, and the patient was to all appearance doing well in every respect; but it was speedily observed that suppurative inflammation of the cellular tissue had supervened; pleurisy with effusion followed, and the patient died at the end of the week, after having miscarried.

Post-mortem. Sero-purulent effusion in the left pleura, with compression of the lung; other organs healthy. The cellular tissue of the thigh on which the operation had been performed, was filled with pus, which had burrowed among the muscles in every direction. On removing the integument from the tumour, it was found to be hard and incompressible in some parts, fragile in others, and crepitating on pressure like dry parchment. In some points the bony tissue had completely disappeared. A division of the head of the tibia shewed that the tumour was composed of a tissue of varied colour, being yellow in some spots, rose-coloured in others, and spotted so as to resemble a section of the brain. The mass of the tumour appeared to consist of two substances,—one of a chalky white and inorganic, the other having an areolar appearance and appearing to contain the former. Here and there masses resembling fat appeared, as well as spots, having the aspect of softened encephaloid matter.

These varieties of diseased structure had entirely replaced the spongy tissue of the bone, but the cartilage was unaffected. The more solid formations of the bone were reduced to a complete shell. No vessel of any size was traced into the tumour.—*Gazette des Hôpitaux*, Jan., 1847.

ON THE TREATMENT OF CERTAIN SURGICAL AFFECTIONS BY ELEVATION OF THE DISEASED PARTS.

M. Gerdy has for some time been in the habit of treating certain inflammatory affections by placing the limb, or part, in such a position as to favour the return of blood to the heart. This plan has this advantage, that it does not exclude the application of the usual means of treatment; but, as is shown by M. Dupuy, it is in many cases in itself sufficient to effect a cure.

The question meets us *in limine*. What are the phenomena which are induced by elevating a part of the body? If the hand, for instance, be allowed to hang down, we observe that it becomes engorged with blood. Place it in the contrary position, and the livid colour disappears, and the vessels empty themselves. It is evident from this experiment that in the first instance the blood accumulates in the most depending part; in the other the reverse occurs, the blood readily finding its way towards the centre of the circulation. What is thus seen to occur in a healthy condition of parts, also happens under certain modifications in disease. M. Dupuy gives the following account of the practical application of the above principles:—

If the thumb or hand be inflamed, the patient is made to lie in such a position that the elbow is maintained in a position higher than the shoulder. The fore-arm is placed perpendicular, supported by cushions, care being specially taken that the circulation is not impeded by bandages; the hand is then enveloped in bandages, to which tapes are fixed, and attached to the top of the bed. These means, with some simple modifications, are likewise made use of in inflammation of the lower extremities. M. Gerdy raises the end of the bed by placing a chair under it, thus raising the foot upon the summit of an inclined plane. Once so placed, and care being taken that no injurious pressure is exerted, the patient must not move from the position even to satisfy natural wants; for he may destroy in a few minutes all the benefits which have been obtained by whole days of repose. Although elevation cannot be so efficaciously applied to the *head* and *trunk* as to the extremities, it yet may be employed to a certain extent. Supposing the *eye* to be inflamed,—the patient will lie with his head high, and on the opposite side to the one affected. Why are inflammatory affections and discharges from the *womb* so tedious in recovery, but for the stagnation of the blood in the organ? Let a woman, who has been accustomed to keep herself in the vertical posture, go to bed, and raise her hips by means of pillows, and she will soon find her case amended. The same principles apply to inflammatory affections of the face, breasts, &c.

The advantage of this plan of treatment is not, however, confined to inflammation, but it is equally serviceable in ulcers, uterine hæmorrhages, and varicose veins. In many instances of the latter disease, in M. Gerdy's wards, elevation alone of the limb has been completely successful. The utility of the plan is also incontestible in varicocele. The communication of M. Dupuy terminates with these conclusions:—

1st. That elevation of the diseased part is able, without the intervention of other therapeutical measures, to cut short certain inflammations, if it be employed sufficiently early.

2nd. That in phlegmon it relieves pain by diminishing the quantity of blood in the part.

3rd. That it advances the cure of engorgements and chronic profluvia of the uterus.

4th. That certain hæmorrhages may be suspended by it.

5th. That it is able to cure certain ulcers of the lower extremities.

6th. That varices and hæmorrhoids areadvantageously modified by elevation.

7th. That where it is not sufficient in itself to effect a cure, it is always a potent auxiliary.—*Archives Générales*, Nov., 1846.

METHOD FOR PREVENTING THE PROJECTION OF THE BONES IN FRACTURE OF THE LEG.

The leg is to be placed in the bent position on the outside, with a common side splint placed above and below, slightly hollowed out to fit the leg. In addition to these, two straight splints are used, padded on one side,—one of sufficient length to extend from the patella to the upper part of the lower third of the leg, the other long enough to reach from the hollow of the knee to beyond the heel. If the straps be now passed round the leg, including the shorter of the two straight splints on the front, and the longer splint on the back of the leg, along with the two bottom splints on the upper and under side, the tibia and fibula above the fracture will be pushed backwards, whilst the foot with the part below the fracture is pressed forwards. In this manner the tendency of the tibia to pass forwards, after simple dislocation or fracture near the ankle, is effectually prevented.—*Ormerod's Clinical Observations*, p. 52.

ON THE COMBINATION OF SENNA WITH MATICO IN HÆMORRHAGE FROM THE BOWELS IN FEVER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I have frequently used matico in cases of hæmorrhage, but I was much pleased about three months ago, with the benefit obtained from combining it with senna, in a case of typhus fever, where hæmorrhage from the bowels took place. As I had previously attended to the state of the liver, &c., I immediately ordered Matico and Foliorum Sennæ, utrq. dr. ij., to be infused in a pint of boiling water, and a wine glassful to be taken frequently. Scybala mingled with blood soon passed the intestines, after which less blood flowed, and by continuing the above mixture in similar doses at various intervals for three or four days, during which time the alvine evacuations gradually improved, my patient soon got rid of this troublesome symptom.

I make these hasty remarks in order that this remedy, (Matico,) which I consider one of the most valuable additions lately made to the Materia Medica, may be more used in the various forms in which disease is constantly taking place in these wondrous coils, whose healthy functions are so essential to the well-being of man, and the inferior animals. I used this combination with a view, not only to arrest the hæmorrhage, but also to prevent the diarrhœa which frequently follows it in fever cases. Anything which will obviate this, is worthy of the attention of those who are anxious to combat, alleviate, or remove the sufferings, in every form, of their fellow creatures.

The publication of Dr. Hartle's valuable communication to Dr. Jeffreys, in the last number of our Journal, has emboldened me to address this note, which, if you think worthy a place in the pages of the *Provincial Medical and Surgical Journal*, you are at liberty to insert.

I am, Sir,

Your most obedient Servant,

ISAAC WATMOUGH, M.D.

Pocklington, Yorkshire,
March 4th, 1847.

BIOGRAPHICAL NOTICE OF THE LATE MR. DODD.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

In the biographical notice of my excellent and lamented friend, Mr. Dodd, published in your last number, there is a slight error which I will thank you to correct at your convenience. I am desirous that this should be done, not so much for my own sake, or for the sake of the eminent friends who at different times saw Mr. Dodd along with me, (viz., Sir James Clark, Dr. Watson, and Dr. Walshe,) as for the sake of *auscultation*, which might be supposed, from this statement, to have faltered egregiously in a very simple case.

The passage I refer to is the following:—"There was much gravitation in both lungs posteriorly, but principally in the right, where the greater portion of the posterior lobe was gorged with blood, and was very friable. There was, however, in this situation, neither fibrous nor any other deposit, except the infiltration of blood, nor hepatization or any adventitious growth, *though it was in this situation, and this only, that disease had been long suspected.*" Now, the truth is, that some years before my poor friend's death, all the gentlemen above mentioned, as well as myself, had, on separate examinations, recognized disease in the upper lobe of the right lung, and subsequently in the left, and none in the inferior lobes.

In some notes now lying before me of the last examination I made, (Sept. 27th, 1846,) I find the signs indicate as close an approximation to the condition of the lungs found on dissection as could reasonably be expected to be made four months before death. The principal of these signs are:—Greater dulness of the right side generally than the left, anteriorly; greater dulness of the left side than the right over the lower lobes, posteriorly; great dulness on the axillary aspect on the right side; a comparatively good sound on the lower portion of the right back. On the *right side*, respiration cavernous above the clavicle, with pectoriloquy, (the parts here greatly sunk in,) also on the sternal border of the subclavicular region; strongly bronchial on the axillary face; in many places the respiration extremely feeble or null, with various forms of rhonchi, crepitant and others. On the lower portion of the back the respiration strong, (puerile;) higher up, in the scapular, intra-scapular, and supra-scapular regions, there is the same marked crepitus as anteriorly. Nearly the same state of things was found on

the *left side*; under the clavicle, the respiration is stated to be markedly bronchial, with the expiration greatly prolonged, and loud bronchophony, (pectoriloquy ?) the bronchial respiration being increased lower down; in the axillary aspect the respiration is more natural, but becoming bronchial towards the pectoral border; on the top of the shoulder the same strong bronchial respiration, with greatly prolonged expiration, as on the front; respiration very feeble on the lower parts posteriorly.

No doubt, part at least, of the conditions of the lower lobes found after death was produced subsequently to my last examination.

I am, Sir,
Yours faithfully,
JOHN FORBES.

London, March 5, 1847.

[The erroneous statement referred to, was made to the gentleman to whom we are indebted for the notice of our lamented associate, by Mr. Dodd himself, and repeated many times. It affords another instance of the peculiar disposition which is so often manifested by phthisical patients, to flatter themselves and others as to the real nature of the disease under which they are suffering.—Ed.]

Medical Intelligence.

EFFECTS OF ÆTHER INHALATION IN PARTURITION.

The following extract of a letter from a correspondent, in reference to the subject, dated Paris, February 25th, may not be unacceptable to our readers:—

"The mind of the profession here, is entirely occupied upon the æther question, to the temporary exclusion of all others. The Baron Dubois read a very interesting paper to the Academy of Medicine the day before yesterday, giving the details of six cases of protracted and difficult labours, in which the vapour of sulphuric æther was inhaled with marked advantage. The particulars will be almost immediately published, but in the interim I may as well tell you that the results of the Baron's experience warrant him in concluding that the vapour of the æther may be inhaled by parturient women:—1st, without any danger to mother or child; 2nd, with advantage to both, in so much as that it destroys all resistance in the voluntary muscles of the perineum, relaxing or rather paralysing them for the moment, without impeding or interfering in the slightest degree with the natural physiological muscular actions of the uterus. The Baron has also observed that the abdominal muscles in their actions in parturition are not at all affected by the inhaled æther.

"The two first cases—both instrumental—one in labour forty hours, the other thirty-six, before the vapour was inhaled, turned out ultimately unfortunate, as both patients died of puerperal fever which was at the time prevailing in the hospital, (La Maternité.) This sad result the Baron does not think can be ascribed at all to the use of the vapour; nor does he on the other hand attribute the immunity of the other patients in the same hospital to it.

"The Baron upon interrogating the patients after delivery as to their sensations during the operation, was informed by all but one, that they felt nothing of what was doing, but that one smiled and would not say what she had felt. It afterwards turned out that this patient, by her confessions to the nurse, was ashamed to say what she felt and thought, as she found herself *engaged*, all the time whilst under the influence of the æther and undergoing the operation of delivery, *with her husband*, in that preliminary process which is so essential to the bringing about of that condition in which ladies like to be who love their lords.

"There is an American dentist here disputing the honour of the discovery with Dr. Jackson. This dentist, a Doctor Wells, or Way, says he made the discovery by induction, in 1844, and that after many successful experiments in his own practice, he travelled from the city of Hertford, in Connecticut, to Boston, to lay the discovery before Dr. Jackson. He was introduced by Dr. Jackson to his class after lecture, and made some experiments before them, but they unfortunately failed, and the young men, to use his own words, denounced him as an impostor. He returned to Hertford, and there continued to use the inhalation in his practice with constant success. Such is his account to the Academy of Medicine and to the Institute here, and his claim to the discovery is under consideration."

HOMŒOPATHY.

Madame Hahnemann, widow of the celebrated founder of Homœopathy, was summoned on the 20th ultimo, before the correctional tribunal at Paris, for having illegally practised the medical art. The prosecution was directed by the procureur du roi, on a complaint by M. Orfila, senior member of the faculty of medicine. Madame Hahnemann declared that she had received a diploma as Doctor of Medicine, in Pennsylvania. She also stated that she never received pecuniary remuneration. M. Delau, M.D., of Montpellier, confirmed the latter fact, and stated that he often consulted Madame Hahnemann. The court pronounced judgment thus:—"Whereas, Madame Hahnemann had, without diploma or certificate available in France, illegally practised as a doctor, and at the same time compounded and sold, without legal authority, medical preparations, offences provided against by the law, the said widow Hahnemann be condemned to 100 francs fine, and to the expenses."—*Lancet.*

MEDICAL APPOINTMENTS.

James Paget, Esq., Professor of Surgery to the Royal College of Surgeons, has been elected Assistant Surgeon to St. Bartholomew's Hospital, in the room of Mr. Lloyd, lately appointed Surgeon.

Dr. R. F. Lindoe has been elected Physician to the Eastern Dispensary, Bath, in the room of Dr. Tarleton, resigned.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members, Friday, February 19, 1847:—H. Davies; T. Pratt; L. P. Madden; J. Nash; J. W. Poland; A. Gozybowski; A. Asmar; R. B. Sawer; E. L. Webb; J. Hutchinson.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, February 18th :—John Bleeck, Bristol; Temple Chevallier Paley, Gretford; Edward Monement, Lynn Regis; George Pretyman Hubbard, Bury St. Edmunds; Anthony Unthank, Nottingham.

ROYAL MEDICO-CHIRURGICAL SOCIETY OF LONDON.

At the Anniversary Meeting of the Royal Medico-Chirurgical Society, held on Monday, March 1st, the following gentlemen were elected officers for the ensuing year:—*President:* James Moncrieff Arnott, F.R.S.—*Vice-Presidents:* Robert Ferguson, M.D.; Jonathan Pereira, M.D., F.R.S.; Robert Liston, F.R.S.; Richard Partridge, F.R.S.—*Treasurers:* George Burrows, M.D.; Benjamin Phillips, F.R.S.—*Secretaries:* George Cursham, M.D.; Fred. Le Gros Clark.—*Librarians:* William Baly, M.D.; Richard Quain, F.R.S.—*Other Members of Council:* George Budd, M.D., F.R.S.; W. F. Chambers, K.C.H., M.D., F.R.S.; P. N. Kingston, M.D.; Thomas Mayo, M.D., F.R.S.; James Arthur Wilson, M.D.; Henry Ancell; Richard Blagden; George Busk; Charles Hawkins; Benjamin Travers, F.R.S.

DEPUTATION TO SIR GEORGE GREY.

We are authorised to state, that a deputation from the Council of the Provincial Medical and Surgical Association, has had an interview with the Right Hon. Sir George Grey, and that from the result of this interview, strong hopes are entertained that a settlement of the questions connected with Medical Reform, satisfactory to all branches of the profession, may be obtained. These hopes are, however, dependent upon some approach to unanimity, in the concession of minor points, being manifested by the different sections of the profession.

OBITUARY.

Died, February 12th, at Enniscorthy, of fever, John B. Macartney, Esq., M.D., F.R.C.S, of Ireland, &c. &c.

February 15th, at Wellington, Somerset, aged 36, Albert Langley, Esq., Surgeon.

February 20th, at Edinburgh, John Pitcairn, Esq., M.D.

February 26th, aged 58, of angina pectoris, George G. Bompas, Esq., M.D., of Fishponds, Bristol, long a member of the Provincial Medical and Surgical Association, and President-Elect of the Bath and Bristol Branch. Dr. Bompas was possessed of considerable scientific attainments, especially in his own branch of the profession—the relief of mental disease. He was of mild and amiable deportment, a model of the christian gentleman, and all his actions were influenced by a feeling of deep responsibility. These characteristics were especially manifested in the performance of his professional duties, and although not an implicit follower of what is called the non-restraint system, his judicious and gentle management of the patients entrusted to his care effected the successful restoration of the mental powers in a very remarkable degree.

February 27th, at Carlisle, Railton Atkinson, Esq., M.D.

Lately, at Dungannon, of fever, William Dawson, Esq., M.D., Medical Officer of the Workhouse.

Lately, at Paris, Dr. M. Cottereau, the associate of M. Raspail.

In December last, at Rio Janeira, M. Felix D'Arcet, one of the Commissioners appointed by the French Government to examine and report on the plague of Egypt.

BOOKS RECEIVED.

The London and Provincial Medical Directory. 1847. London: Churchill. pp. 288 and 362.

Medicines, their Uses and Mode of Administration, &c., &c. By J. Moore Neligan, M.D., Edin., M.R.I.A., Licentiate of the College of Physicians of Ireland, Physician to Jervis Street Hospital, &c., &c. Second Edition. Dublin: Fannin and Co. 1847. 8vo. pp. 485.

On the Mechanism of Respiration. By Francis Sibson, Esq. (From the "Philosophical Transactions.") London: Taylors. 1846. 4to. Plates.

On Diseases of the Skin. By Erasmus Wilson, F.R.S., Consulting Surgeon to St. Pancras Infirmary, Lecturer on Anatomy and Physiology to the Middlesex School of Medicine, &c., &c. Second Edition. London: Churchill. 1847. 8vo. pp. 482. Plates.

On Cataract, Artificial Pupil, and Strabismus. By F. H. Brett, Esq., M.D., F.R.C.S., Surgeon to the Western Institution for Diseases of the Eye, &c., &c. London: Churchill. 1847. 8vo. pp. 89. Plates.

Report of the Liverpool Eye and Ear Infirmary, for the year 1846. Liverpool: 1847. 8vo. pp. 33.

Notes on the Inhalation of Sulphuric Æther in the Practice of Midwifery. By J. Y. Simpson, M.D., F.R.S.E., Professor of Midwifery in the University of Edinburgh, and Physician Accoucheur to her Majesty in Scotland. (From the "Monthly Journal of Medical Science.") Edinburgh: Sutherland and Knox. 1847. 8vo. pp. 11.

Medical Statistics; their Force and Fallacies. A Lecture delivered in Park Street School of Medicine, November 4th, 1846. By James F. Duncan, A.M., M.B., Fellow of the King's and Queen's College of Physicians, Physician Extraordinary to Sir P. Dun's and Mercer's Hospitals, &c. Dublin: McGlashan. 1847. 8vo. pp. 42.

TO CORRESPONDENTS.

Communications have been received from Mr. F. Buckell; A Member; the Sheffield Medical Society; Mr. W. C. Worthington; Chirurgo-Medicus; Dr. Cullen; Mr. W. F. Clarke; Mr. P. Wright.

The Æther-Quackery shall be noticed in the next number, with some other points connected with the subject of Æthereal Inhalation, which we have been compelled to omit.

It is requested that all letters and communications be sent to Dr. Streeten, Foregate Street, Worcester. Parcels and books for review, may be addressed to the Editor of the Provincial Medical and Surgical Journal, care of Mr. Churchill, Princes Street, Soho.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

A COURSE OF LECTURES ON CLINICAL MEDICINE.

By W. R. Basham, M.D., Physician to the Westminster Hospital.

Lecture VIII.

Case of Ptosis, symptomatic of cerebral disease: History of the case, treatment, and convalescence.—Difference in the characters of ptosis as an affection per se, and as a symptom of more remote disease. Loss of power in the second, third, and branches of the fifth and seventh nerves.—Condition of the parts to which these nerves were distributed; extent of the local paralysis; reasons for referring the origin of the attack to apoplexy. Progress of the treatment, and present condition of the patient.

Gentlemen,—The case of ptosis of the left eye, with partial paralysis of the retina, loss of mobility in the iris, and of sensation in the nerves distributed to the scalp of that side, with subsequent exaltation of sensation, is of much interest, of rare occurrence, and very instructive as regards the therapeutic action of the remedies employed. The man was discharged last week convalescent. The history of the case declares the disease to have been in its origin caused by some local injury occurring at the base of the brain, after the manner of an apoplectic attack, and involving the optic nerve and branches of the third, fifth, and seventh.

A. B., aged 49, married, a labouring man, of short stature and dusky complexion, complained of acute paroxysms of pain confined to the left half of the scalp and neck, also dropping of the left eyelid, with darting lancinating pain in the ball of that eye. He was placed in Burdett ward. About fourteen days since, while sitting at the fire he suddenly fell from his chair insensible. He was immediately bled by a surgeon who was quickly in attendance; before a pint of blood was drawn sensibility returned, and he then became conscious of the closure of the left eye, with loss of vision in that eye, and a numbed sensation in the scalp. There was no paralysis of any other organ, or deficiency of sensation in any other portion of the surface; no incontinence of urine or fœces. Has been merely purged by some black draught, and has taken no other medicine since the attack. One half of the scalp bounded by the median line and commencing at the left eye, and passing upward to the sinciput and thence to the occiput, but not descending lower than the nape of the neck, and along the edge of the trapezius muscle for nearly an inch and a half, then abruptly passing in front and upwards to the chin, the left cheek and ear being included, so that exactly one half of the cranial surface was involved in this state of altered sensibility. The tongue is not affected, nor is there any loss of muscular power except in the action of the levator palpebræ of the left eye, the eyelid being depressed so as to half close the eye. There is no want of power in the orbicularis palbebrarum of this eye, as by its action the lids can be completely closed, and indeed by a voluntary effort can be tightly closed, effectually resisting any attempt to raise the upper lid mechanically by the finger till the action of the orbicularis is relaxed. The state of sensibility in these parts is not that of entire deprivation; it partakes more of the condition of some forms of neuralgia, the affected region being at times numbed and insensible to external impressions; at other times the sensibility is much exalted, and acute excruciating paroxysms of pain dart through the eyeball, cheek, and even over the scalp to the back of the head. When the left lid is raised the left eye is natural in appearance, the cornea perfectly clear; sclerotic, not injected; margin of the pupil well defined; the pupil free from cloud, opalescence, or any coloured appearance; the iris, is however, only sluggishly sensitive to the action of light. The motions of the eyeball are not made with precision, the patient appearing to have but an imperfect command over them; when directed to look to the right or left or straight forward, these several acts are hesitatingly performed. The power of vision in this eye is deficient. When the lid is raised he perceives only a greyish light, which he can distinguish from the darkness when the lid is closed, but he can recognize no object even held ever so close. The sight of the right eye is perfect. Lancinating pains are frequent in the ball of the left eye. These paroxysms are worse at night. Has not slept for many nights. The features of the left side, when the face is at rest, do not appear affected; but when he speaks a singular expression occasionally passes across the features, as if from want of consent in the action of the muscles of the left with those of the right side. The general health does not appear impaired; tongue clean; pulse small and regular; heart's sounds natural.

He was ordered Quinæ Disulph, gr. ij.; Pilul. Hydrargyri, gr. ij., ter die. Hydrarg. Chlorid., gr. iv.; Pulv. Scammon. Co., gr. x., statim. Morphia Acet., gr. ss., omni nocte.

On the fourth day from admission, he is reported to have suffered much less pain, and to have passed much better nights. An improved diet was ordered. On the tenth day, it is stated that the pain is much less severe, the intermissions being longer; slight tendernes of the gums; has acquired a greater power over the affected lid, and can slightly raise it; the iris is less sluggish to the influence of the light, and the patient states that he can perceive the light stronger and brighter. The mercury was withdrawn; Quinæ Disulph. gr. ij.; Extr. Aloes, gr. j., ter die.

On the twenty-first day, had recovered nearly complete power over the affected lid; the pain in the eye and scalp is much diminished both in intensity and frequency; he can distinguish the bars in the window, and even intervening objects faintly. On the twenty-ninth, vision had become nearly perfect with the left eye; could distinguish most objects with the left eye alone; some indistinctness for distant objects; paralysis of the levator palpebræ of the left eye has entirely disappeared, the aspect of the two eyelids being identical. The state of the features when speaking presents now nothing remarkable. He is quite free from pain, but states that he occasionally feels the top of his head numbed, and when scratched, deficient in sensation, but that this feeling is not constant; the general health is good, and it is hoped that in a short time all vestiges of this cerebral affection may be removed.

In offering to you some clinical observations on this case, let me first direct your attention to the symptom most palpably evident,—one that without any complaint on the part of the patient you could not fail to notice, namely, the dropping of the left eye-lid, termed ptosis, from a Greek word πτωσις, simply meaning to fall down. Ptosis may be considered either as an affection *per se*, or as a *symptom* of internal cerebral disease. The first is dependent on certain integumentary conditions,—such as hypertrophy of the cellular tissue of the upper lid, or excess of integument, so that power of the levator palpebræ is overcome by the mass of the lid to be raised. It is comparatively a trivial affection, and is frequently relieved by surgical operation, and it must be carefully distinguished from the dropping lid, which, as a symptom, is one of considerable moment, as indicating some serious organic lesion in the encephalon.

When ptosis is a symptom of cerebral disease, it does not occur alone, there are usually several other concurring conditions sufficiently explicit, pointing to the cerebral centre as their source.

Now in this case, the second point of observation was the numbed and deficient sensibility of the cheek, forehead, scalp, and chin of the left side. Our attention was next fixed upon the loss of vision; the left eye, unable to distinguish form or colour, was yet faintly sensible to the difference between light and dark. We next noticed the sluggish motions of the iris to the action of light; then the uncertain action of the muscles of the eye-ball; and lastly, the play of the features on the opposite sides of the face, was not consentaneous when the patient spoke or laughed. This circumstance was evident; but when the countenance was at rest, no want of unity of expression appeared to exist. With such a category of symptoms could there be any doubt as to the presence of some cerebral condition, as the cause of this aberration of sensibility and motion? But I wish to make this clearly evident to you, and in doing so, you will not fail to perceive how confessedly dependent is pathology upon anatomy and physiology, and how little of the nature or cause of disease could be known or discovered without the aid of these sciences,—sciences which are as indisputably the foundation of all true pathology, as they are indispensably the basis of all certain, well-directed, and efficient therapeutical practice.

The muscular power of the levator palpebræ is dependent on a branch of the third nerve; the perceptive faculty of the eye is regulated by the optic nerve; the sensibility to the influence of light, and the mobility of the iris, arise from the ciliary nerves, derived from the ophthalmic ganglion, which is formed by a portion of the fifth, and a branch of the third nerves; the motions of the eye-ball are influenced by the third or motor occuli as it is called; the sensitiveness of the skin of the cheek, scalp, forehead, and chin, is due to the fifth; while the muscles of the face are guided in their motions by the branches of the portio dura of the seventh. We thus find that the second, third, fifth, and seventh nerves, are deprived of a certain amount of the healthy influence exercised over the muscles and parts to which they are distributed. There was something singular in the degree or extent to which these nerves were deprived of their accustomed power; in none could it be said that there was total paralysis, or complete loss of power; vision was not totally obliterated; the patient could distinguish between light and dark; sensation in the cheek, forehead, and scalp, was not entirely lost; the parts were rather numbed than paralysed; the laying of the finger gently on the forehead or cheek was not felt; but if the skin was pinched he winced. Moreover, there was at times much exaltation of sensibility in these parts, lancinating excruciating pain darting in paroxysms through the affected nerves. The mobility of the eye-ball was only imperfect—not destroyed. When told to look to the right or left, upwards or downwards, the motions were made without precision,—awkwardly, hesitatingly, as though the muscles were not perfectly under the influence of the will. It could not be said that the iris was insensible to light, it was only sluggish to its influence. The injury therefore to these nerves was partial and not complete; their functions may be said to have been suspended rather than destroyed. From so many nerves being implicated, and the partial manner in which these were affected, it could not be doubted that the morbid cause was operating at the roots of these nerves,—at their cerebral centres, not at the extremity of their peripheral distribution. To the brain, therefore, we were to look for the special morbid cause.

Now, the history of the attack materially aids us in our diagnosis. Sitting by the fire, he suddenly becomes insensible, and falls after the manner of a fit, from which he recovers to find a surgeon extracting blood from his arm. As complete consciousness returned, he became aware of the loss of sight in the

left eye, and that he could not raise the lid, and that he could scarce feel his left cheek or the scalp of his head, which felt as he stated as if *asleep*. Can we for a moment doubt that this attack was of the nature of apoplexy; in its mildest form perhaps, but nevertheless dependent on a lesion of some portion of the encephalic apparatus. It would be idle in the absence of all proof, to speculate upon the particular spot in the brain in which this lesion had occurred; it is more than probable, however, that the base of the brain must be the spot, but whether in the thalamus, corpus striatum, pons Varolii, or any other portion having relation to the roots of these nerves, it is useless to speculate upon.

Considering then this case to be in its origin cerebral, and possessing all the features of an apoplectic attack, with the formation of a clot in some part of the encephaloid mass, the treatment was based upon those principles which guide us in ordinary cases of paralysis from apoplectic causes. From the mildness of the symptoms, and the paralysis being so limited, a favourable prognosis was pronounced. It was hoped that the influence of mercury in alterative doses might promote the removal of the morbid influences acting on the nerves. With this intent, blue pill was given twice a day, in ten grain doses; and to check the intermitting character of the paroxysms of pain, which so violently affected him, quinine was combined with it. This treatment was pursued till the gums faintly indicated the influence of mercury in the system, and from that moment there was a daily and visible amelioration of all the symptoms. The paroxysms of pain first became less urgent; an increasing power over the levator palpebræ was soon evident, and the powers of vision were sufficiently improved to enable him to define the bars of the windows. The mercury was now withdrawn, and its place supplied with small doses of purified aloes, in conjunction with the quinine. You have seen the patient to-day; vision is not yet perfect; when the right eye is closed he can distinguish persons, but not clearly; he can number those standing before him, but he cannot clearly recognize features or colour with the affected eye. The restoration of the levator palpebræ is, however, complete; the two eyes exactly correspond, and he can raise and drop the left eye-lid at pleasure; the motions of the eye-ball are precise and regular, and the iris of the left eye is now equally sensible to the influence of light as the right.

As a specimen of local and partial paralysis from apoplexy, this case must be viewed as one of much interest; and it is equally so in respect of the influence that appropriate remedies exercise over the morbid cause of the paralysis; and to you, gentlemen, it is an example, I hope not thrown away, of the value and absolute utility of anatomical and physiological knowledge, in reading the mysteries of diseased action; for it must be clear to you, that if you did not know the distribution of the several nerves implicated, and were unacquainted with the peculiarity of the special functions they severally perform, it would have been impossible for you to interpret the source from whence these symptoms were derived.

ON THE MEANS BY WHICH UTERINE HÆMORRHAGE IS SUPPRESSED WITHOUT ARTIFICIAL ASSISTANCE.

By Thomas Radford, M.D., Consulting Physician to the Lying-in Hospital, &c., Manchester.

A knowledge of the inherent powers of the living body to stop hæmorrhage from the uterus, is of the highest importance to the obstetrician. Without an intimate acquaintance with their mode of operation, he can never practise successfully. All the principles of our art ought to be based on a clear and comprehensive knowledge of the plans adopted by nature when danger exists and threatens the destruction of life. On this account I have not hesitated to lay a brief statement of them before the profession. Although the following observations may not possess the attraction of originality, yet I believe, that every well-thinking and judicious practitioner will admit the value of such, if judiciously made. The following is an enumeration of the natural anti-hæmorrhagic powers:—1st, syncope; 2nd, coagulation of the blood; 3rd, effusion of lymph and obliteration of the vessels; 4th, re-union of the detached portion of the placenta to the uterus; 5th, death of the child; 6th, uterine contraction; 7th, spontaneous rupture of the membranes; 8th, spontaneous separation of the placenta.

Complete or partial syncope sooner or later is induced when blood is discharged from the vascular system; the difference depends on a variety of contingent circumstances which may exist at the time. When we wish to make a quick and powerful constitutional impression by venesection, we make a larger orifice, so that the blood runs *pleno rivo*. We place our patient erect; and if of feeble constitution, or if the habits are bad, the effect is sooner produced, and continues longer. So in floodings, we find the relative effects very different; some women bear an immense loss without apparently suffering much from it, whilst others rapidly succumb from the same or even a less amount of discharge. Sudden and profuse gushes of blood speedily produce fainting, but slow and dribbling hæmorrhages continue for a considerable length of time without producing this effect. Although these latter kind of floodings do not so suddenly depress the vital powers, yet they insidiously undermine them, and in many of these cases the life of the patient is ultimately placed in more jeopardy than in those of the former class, provided the patient is not immediately destroyed.

Great caution is necessary not to allow a principle, based on false security, to lead the practitioner to procrastination in adopting active measures; his judgment ought not to be led astray by the quantity of blood which has been already discharged, or is now being lost, but he should invariably direct his attention to the influence produced on the vital powers, as the immediate and remote effects of loss of blood are relatively

so different in different women. These different relative effects depend on a variety of circumstances,—on the age, habits, and constitution of the woman; on the condition of the brain and general nervous system; on the functional and structural organic state of the thoracic and abdominal viscera; on the state of the uterus; on the position of the patient when the accident happens; and on the mode by which the blood is discharged, &c. When we are considering syncope as a natural and sanatory effect, capable of producing such favourable changes in the general circulation, and also in the vessels from which the blood is poured, which tend to suppress the hæmorrhages, we ought not to overlook the fact that syncope is sometimes the precursor or harbinger of death.

Our diagnosis here should be as exact as possible, to judge between salutary and mortal syncope. If this state of the vital powers is produced by a large and sudden but not continued gush of blood, or by a less quantity lost when the patient is in the erect position, then conditionally it may be considered as likely to be useful. But if, on the contrary, the hæmorrhage has been going on for a long time, although slowly yet insidiously, and thereby at last producing the accumulated effects of loss of blood upon the system, we must view it as the prelude of death. By its salutary power the action of the heart and arteries is at first totally suspended, and afterwards lessened in force and frequency, by which less blood is sent to the uterus, and time is afforded for coagulation to take place within or in the immediate vicinity of the vessels.

When blood is effused it speedily coagulates if their exists any substance which affords a *point d'appui* for the commencement of this process. It is said by physiologists, that the blood is more disposed to assume this change in case of excessive hæmorrhage. When one of the umbilical arteries or veins is ruptured within the substance of the placenta, and the structure of the uterine and fœtal surfaces are uninjured, the effused blood being confined soon forms a clot, which effectually stops further bleeding. Other similar accidents happen during the same pregnancy in different parts of the placenta. But if the injury extends through either surface coagulation does not so easily take place, as the blood so readily escapes externally into the vagina, or internally into the amnion bag, according to the situation of that portion of the organ which is disrupted. The characters of clots which form and are seen in the substance of the placenta vary according to the length of time which has elapsed since the accident. Sometimes hæmorrhage happens between the uterus and the placenta, and is confined in the centre by the circumference of this latter organ firmly maintaining its adherence. If this effusion is not great, coagulation takes place, and subsequent changes are accomplished, so that pregnancy goes on.

In disruptions of the placenta the coagula form in its interstitial structure. In several fatal cases of *post-partem* hæmorrhage in which I have examined the uterus after death, I have found a small portion of adherent placenta, whose structure was so entirely pervaded with coagulated blood as at first to be mistaken for a clot; but on a more minute examination its true character was discovered. In another fatal case of this kind the practitioner in his report of the *post-mortem* examination, represented the infiltrated portion of placenta as a polypus. Coagula form within the uterine venous openings, upon and in the interstitial tissue of the placental tufts which enter into them, and are found left after the separation and expulsion of the placenta. The meshes of the decidual membrane afford a surface on which coagula form and adhere. Dr. Blundell and other writers speak in the highest terms of the anti-hæmorrhagic powers of the large clots of blood which form in and fill the vagina, but which in my opinion are overrated. Although I do not admit that they prove as valuable a resource in flooding as has been mentioned, yet I would caution the obstetrician not to rashly remove them, for if they do not directly arrest the bleeding, they indirectly assist by giving support to those formed above in the interstitial, placental, and decidual substances, which are of the greatest utility. Nevertheless, the presence of coagula in the vagina ought never to interfere with our more important duty to explore, so as to ascertain the condition of the os and cervix uteri, the presentation of the child, or if the placenta is anormally fixed.

The important and valuable principles first fully developed by Dr. Jones, are admirably and indeed effectively adapted to prevent bleeding from arteries laid open by injuries, or by surgical operations in other parts of the body, but are not applicable in cases of uterine hæmorrhage. Although the uterine arteries have a similar organization to that possessed by those elsewhere situated, yet they differ in size at different periods and perform very different offices, in the ungravid, in the gravid, and during the parturient and puerperal periods.

It is stated by some writers that a re-union takes place between the uterus and the detached portion of placenta, and that a return of flooding is thereby prevented; but my opinion is entirely at variance with this assertion, and from a great number of observations made by examination of the placenta after its expulsion, I am convinced that a recurrence of the hæmorrhage from the placenta is alone prevented by a change which takes place in the organization of the detached portion.

The death of the child in utero may be immediately produced by hæmorrhage, or it may more remotely happen by the impairment which its organic system has sustained. But it is not to be understood that the child is invariably or inevitably destroyed when hæmorrhage occurs, but on the contrary, it is born

alive in the great majority of these cases. However, statistics shew that this event happens sufficiently often to justify the opinion that I have formed, that flooding does not take place, or if it does, it is very moderate in degree in such cases. Under normal circumstances, the utero-placental and the placento-fœtal circulations exercise a reciprocal, although not an equal, influence on each other; and that there exists on the part of the placento-fœtal, a great and essential derivative power. But the death of the child, immediately to a certain degree, and ultimately altogether, changes the functional and structural conditions of the placenta. "The stimulus of necessity" on the part of the child for a supply has ceased, and consequently is altered. The arteries convey to the uterus less blood, and so there is less accumulated in the veins to be returned to the general circulation. The passage of blood is most likely first stopped in the umbilical arteries; and very soon after, if not simultaneously, that through the umbilical vein also ceases, and consequently both the arterial and venous ramifications in the placenta would have no blood passing through them.

The placenta would therefore at first be in a somewhat similar condition to that which exists after the birth and separation of the child; but after a short time it undergoes farther progressive changes in its organic condition. Its structure becomes less spongy and more firm; the calibres of the vessels are lessened and filled with fibrin; its decidual surface has a dried and shrivelled appearance, and is dotted with small coagula of different aspect, some being recent, while others look old and fibrinous.

During my practice I have attended a great number of labours in which the child was dead, and I have invariably observed, that there was little or no sanguineous discharge when the placenta was expelled, or afterwards, as that which is termed the lochia. There were four cases of placenta prævia in this number, which I shall briefly cite.

In one case the hæmorrhage happened at the sixth month. Cold water, &c. &c., and the plug were used; opium was administered, &c. These means effectually restrained the bleeding. It however returned with violence in a fortnight, and again the same plan was successfully adopted. After this time the movements of the child became gradually more imperceptible, and at last ceased altogether. Six weeks after the first attack of the hœmorrhage labour came on, but there was no bleeding; the placenta separated on one side, so that the head passed by it. When the child was born it had the appearance of having been some time dead; the placenta was also considerably changed; there was no farther loss of blood.

In the second case an excessive hæmorrhage happened at the seventh month; there were no pains. Plugged successfully, cold applications, &c. In a month the bleeding recurred, but as there was no evidence of labour, the plug was introduced, and the means before-mentioned used. The hæmorrhage ceased. The death of the child was indicated by the usual mammary changes, &c. At the end of a fortnight labour pains came on, and as the os uteri allowed, I passed the hand, separated the edge of the placenta, and turned and delivered the child, which had evidently been dead some time. There was no flooding.

In the third case the flooding first took place from the seventh to the eighth month, and was afterwards several times repeated. The last attack was so violent as to threaten danger. The os uteri being rigid, the plug was introduced, an abdominal bandage applied, &c. She never felt the child after the last attack. The labour did not come on for a fortnight, but there was no farther loss of blood.

The fourth case was excessive flooding at the eighth month. There being no signs of labour, and the os uteri being firm and undilated, the plug was introduced, and the abdominal bandage applied, &c. The child had been vigorous up to this date, but since has not been felt to move. She went on to her full period, and as there was no flooding, the placenta was partially detached, the membranes ruptured, and the uterus acting well, the case was left to nature. The child was putrid, and the placenta was much altered. No after discharge occurred.

The gravid uterus mainly consists of muscular fibres, which are greatly developed at the end of pregnancy. The blood-vessels, arteries, and veins, have acquired a great size,—especially the veins. The muscular fibres are longitudinal, circular, and oblique, each set being interlaced with the others. Portions of this tissue are intimately distributed around the arteries and veins, and indeed the outer coats of these latter vessels are composed of it. The arteries, which are considerably elongated, take a spiral and tortuous course through this texture; the veins are situated in different tiers in it, and each division freely inter-communicates by oblique openings with each other, and with those which lie nearest to the uterine cavity. Mr. Owen makes the following appropriate remarks:—

"Every vein, however, when traced to the inner surface of the uterus, appeared to terminate in an open mouth on that aspect; the *peripheral* portion of the coat of the vein, or that next the uterus, ending in a well-defined and smooth semicircular margin, the central part adhering to, and being continuous with, the decidua. In the course of this dissection I observed that when the veins of different planes communicated with each other in the substance of the walls of the uterus, the central portion of the parietes of the superficial vein invariably projected in a semilunar form into the deeper-seated one, and when (as was frequently the case, and especially at the point of termination on the inner surface,) two or even three of these

wide venous channels communicated with a deeper sinus at the same point, the semilunar edges decussated each other, so as to allow only a very small part of the deep-seated vein to be seen. It need scarcely be observed how admirably this structure is adapted to ensure the arrest of the current of blood through these passages upon the contraction of the muscular fibres with which they are every where immediately surrounded."—Note to the paper, "On the Structure of the Placenta," in John Hunter's works, edited by Palmer, page 68.

Mr. John Goodsir passed a probe into a vein, and then slit it up with scissors, and repeated the same plan whenever he found the entrance of another branch. He found the anastomosis of the veins increase as they approach the internal surface of the uterus. "The spaces which they inclosed, presenting the appearances of narrow flat bands. At last, in introducing the probe under the falciform edges of the venous orifices, it was found to have arrived at the placental tufts, which could be seen by raising the edges of the falciform edges, &c."

The tissues of the fundus and body of the uterus are first developed, and afterwards the cervix and os. These changes are progressive, and gradually enlarge the cavity as the fœtus and appendages increase in size. In normal pregnancy the muscular fibres are quiescent, and passively yield to this law, which has been imposed on the organ for the safety and growth of the ovum; but as soon as the fœtus is matured, so that it is capable of extra-uterine existence, a new law predominates, and contraction follows. The body and fundus being more muscular, are endowed with greater irritability and contractility than the cervix, and at first they are chiefly employed in expulsion. Some writers deny the existence of muscularity, and consequently contraction, in the cervix, but the great majority admit that it is possessed of a great number of circular and some few longitudinal fibres. Its first change in labour is to dilate, to allow the passage of the child and secundines. This is said by some to be the effect of a wedge, formed by the membranes, mechanically forced down by the power above. Others again say it is a muscular act. My opinion is that it contracts when required in the process of labour. Normal causes applied induce irregular contraction. Dr. Campbell says that a contraction of this portion of the uterus is mistaken for what is described as hour-glass contraction of the body of the organ.

Normal uterine contraction, which is of two kinds, —first, temporary or alternate,—secondly, permanent or tonic, is able to perform the parturient function when every circumstance which acts directly or indirectly upon this process, is equally favourable for this end. By its power the child and placenta is expelled, and the woman is secured against the dangers of flooding. It must not be partial in its operation, in order to achieve these important objects; but it must be universal; every muscular fibre must be actively engaged to afford a sanatory and protective influence. It is necessary to remember the length and tortuous course of the arteries, and also the course, relative position, and the peculiar valve-like openings of inter-communication of the veins; the imbedment of these vessels in the muscular tissue, and surrounded by it. We must also not overlook the fact that the calibre of these vessels is fully occcupied by the blood passing in this state through the parietes of the full gravid uterus, whose superficies is extensive. Then we can be at no loss to understand why uterine contraction is so powerfully anti-hæmorrhagic. The measurement of the surface of the gravid uterus at the end of pregnancy or beginning of labour, compared with the same organ when regularly and tonically contracted after the expulsion of its contents, is very different indeed. Dr. Blundell emphatically remarks that the muscular fibres act as so many ligatures upon the vessels.

Notwithstanding the beautiful adaptation of the means to the end, when all is in a normal state, we frequently find in practice that there are constitutional and local conditions,—physical and moral causes, which produce upon the uterus anormal effects; and hence we find its action perverted, or altered in power, and in some cases altogether suspended. This anormal state of uterine energy exists in every degree, and comes on at all times during or after labour, constituting what is usually called cases of complete or partial atony, or irregular contraction. Partial contraction assumes the character of spasm, and may seize any portion of the uterus to any extent, and to any degree of intensity. The fundus may firmly contract, whilst the body and cervix are in a relaxed state; the circular fibres of the body may contract, and yet the fundus and cervix be uncontracted, and thus constitute hour-glass contraction. Sometimes the os and cervix contract, and the upper portion of the organ is atonic, thereby affording a shut-up cavity, in which the placenta is sometimes incarcerated, and sometimes a large quantity of blood is effused into it, which is called internal flooding.

Different sets of muscular fibres irregularly and successively contract, and change in such a way as to form small chambers, which open out of the general uterine cavity. I will briefly cite a case selected from many others, illustrative of the capricious state (if I may use the term,) of the muscular fibres. I was requested by Mr. P., to visit a patient who was flooding, one child being born, and another thought to be still in utero. Upon my arrival the hæmorrhage continued. On placing my hand on the abdomen, I found the uterus large and generally doughy; about the middle was a hard and resistant portion, at the boundary of which there was felt a vacillatory sensation, which

continued some time; it yielded in a short time, and another hardened portion was found. The sensations produced by these contractions led to the notion of the existence of a second child. I now introduced the hand, and only found the placenta and some coagulated blood. My attention was called to a circular opening at the anterior part of the womb, through which I could pass two fingers; to my surprize this spasm yielded, and was soon succeeded by a similar state in another part. I endeavoured to produce uniform contraction, but this migratory irregular action continued for some time, notwithstanding a large dose of laudanum was given.

Irregular contraction of a portion of the uterus in the vicinity of the placenta causes partial separation of it, and flooding happens. Again, one portion of the uterus in the same neighbourhood may be atonic, and the rest of the organ well contracted, and so flooding continues. Whenever and by whatever cause a partial contraction of the placenta happens, irregular contraction of a portion of the uterus is nearly sure to take place. Spasm or irregular uterine contraction, causes hæmorrhage in two ways,—first, by directly producing a partial disunion of the placenta from the uterus; secondly, by acting mechanically, so as to impede the free return of blood along the veins to the heart. In all cases of flooding, except when the placenta is anormally fixed to the uterus, regular, equal, and firm uterine contraction will always secure the patient against the dangers of the accident. I hesitate not to say always, because an extensive hospital practice has enabled me to speak positively on this subject. But if the uterus is in any degree atonic, or its action irregular, however partial, hæmorrhage will happen, which can alone be arrested by restoring uniform contraction, or an equilibrium of action throughout the entire uterine muscular tissue.

These remarks are made with a knowledge of Dr. Gooch, Dr. Rigby, Dr. Ingleby, and Velpeau's opinions. Dr. Gooch relates a case of *post-partem* hæmorrhage, in which he says the uterus was firmly contracted, and depended on the exalted state of the general vascular system.—"Medico-Chirurgical Transactions," vol. xiii., part 1. Mr. Roberton has already shown that Dr. Gooch's inferences are not true, (*North of England Journal*;) I, however, do not think that he has explained the cause of the discharges in Dr. Gooch's case, in supposing that the uterus relaxed. My opinion is that there existed irregular contraction, some portion of the organ being in an atonic state, not accessible to Dr. Gooch's hand externally applied on the abdomen.

In placenta prævia the hæmorrhage is increased by uterine contraction, as long as the placenta is partially adherent.

Spontaneous rupture of the membranes, and the discharge of the liquor amnii, induces uterine contraction, which effectually restrains hæmorrhage in the majority of cases of accidental, and in those cases of unavoidable, floodings which are caused by a partial implantation of the placenta over the os uteri.

The natural powers are equal to the achievement of most important ends during labour, when mechanical causes exist which oppose the passage of the child in labour.

When the placenta is placed centrally, or nearly so, over the os uteri, it is sometimes spontaneously expelled before the child, an event which happens more frequently than has been usually supposed by obstetricians. Hippocrates was acquainted with the fact that the placenta is sometimes spontaneously expelled before the child, and knew the danger of this event to the child. He says, "that the after-burthen should come forth after the child; for if it come first, the child cannot live because he takes his life from it, as a plant doth from the earth." The father of medicine no doubt knew that the coming forth of the after-birth before the child, was not attended with the same risk to the mother as to her offspring, or he would have recorded his opinion upon this point.

Obstetric writers up to comparatively a recent date, since the time of Hipocrates, have not mentioned this subject, although they must have met with cases, and have been acquainted with his writings. Whenever the placenta is partially detached in cases of placenta prævia, and the child is still alive, hæmorrhage inevitably happens. The quantity of blood discharged is not always the same, but is more or less profuse, according to the concurrence of a number of contingent circumstances. Sometimes the discharge is very excessive when the placenta is only slightly separated, and sometimes the hæmorrhage is moderate when the placenta is extensively loosened. But the aspect of matters is changed by a complete separation of the placenta; the variation in the degree of discharge marked above, is not now observed to exist; there is a total cessation of the bleeding, and it forms an exception to the general rule when hæmorrhage happens after the placenta has been completely loosened from its attachments, and protruded from the uterus into the vagina.

On the 10th day of December 1844, I delivered a lecture on galvanism applied to the treatment of uterine hæmorrhage, in which I then stated that without any great pains I had brought forward before the profession "thirty-six cases illustrative of her (Nature's) powers, in expelling the placenta before the child." This number might have been very considerably augmented by bringing cases which were then already published, but my object was not to make a great parade of authorities, but only to mention such as were in the reach of every obstetric practitioner. At the time, I made the following remarks:—"Now, the bulk of these cases, gentlemen, have been detailed without any

specific practical object, and, consequently, are more valuable to my present purpose than if they had occurred to myself, and had been brought forward to serve my own particular views. You may refer to many of them yourselves, and you will find in nearly all of them that the hæmorrhage was suppressed after the placenta was thrown off."—*Provincial Medical and Surgical Journal.* 1844. p. 603.

Since then Dr. Simpson published (in the *London and Edinburgh Monthly Journal of Medical Science,* No. 51, March, 1845,) tables of 141 cases, some of which, however, were not cases of spontaneous expulsion. These tables include those cases which had already been brought forward by me, and some others which were afterwards communicated by me.

By the kindness of several professional gentlemen I have collected sixty, which shew the following results:—In all, the hæmorrhage was great before the placenta was loosened; in fifty-five of this number it was completly suppressed after the separation of the placenta; in three it continued, of which in two it was slight, in one it was profuse; in thirteen the placenta was forcibly expelled followed immediately by the child; in twenty, two to three hours elapsed; in twenty-seven the child was turned and extracted immediately. Forty-five women recovered, fifteen died. Fifty-five children were lost, five only living.

In the above mentioned cases there is only one in which flooding to any degree continued after the placenta was completely separated, and this proved fatal. In the remaining number of those who died, the fatal impression was made before the separation was accomplished. In a few cases already published slight hæmorrhage continued, and some deaths occurred not dependent on the after bleeding, but as above mentioned from the effects produced before. These cases must not be allowed to invalidate the inference, "that hæmorrhage ceases when the placenta is completely separated." We can readily understand why this should happen if we physiologically investigate how the utero-placental, and the placento-fœtal circulations are carried on.

When a partial separation of the placenta takes place whilst the fœtus in utero is still living, hæmorrhage is sure to occur, because two sources exist from which blood can escape. (*Vide Lancet,* No. 9, February 27, 1847.) One current of blood comes through the medium of that portion of the placenta which still adheres to the uterus, and is discharged from the surface of that portion of the placenta which is detached; the supply of blood is demanded by the child from the maternal system, and when sent, it cannot from the nature of the accident return, and therefore, is lost: the other current of blood which runs away, comes from the uterine venous openings. But when there is complete disjunction of the placenta from the uterus, the case stands quite different; no maternal blood can be discharged from the placenta, because it is now placed in the position of a foreign body, having no structural or physiological relation to the womb. Rupture of the membranes either simultaneously happens, or precedes the separation and expulsion of the placenta, except in cases where the entire ovum is expelled at once, which very rarely occurs. The uterine contraction, which must at this time have been strong, is now increased, which brings the presenting part of the child to occupy the lower segment of the uterus, and to bear mechanically on the exposed venous openings. The calibres of the vessels are also diminished.

Notwithstanding the truth of the above conclusion,—that complete detachment of the placenta suppresses hæmorrhage, yet we must not allow ourselves to fall into serious error to wait in expectation of such an event,—because, first, there do not exist signs which will lead us to expect such a termination; secondly, the vital powers may be completely sunk before the separation is achieved. Hamilton, Collins, and Dr. Ramsbotham, senior, were all acquainted with this fact.

March 10, 1847.

OBSERVATIONS ON THE TREATMENT OF ORCHITIS BY COMPRESSION.

By George Frederick Wills, Esq., Surgeon, Crewkerne.

The beneficial effect of pressure in cases of inflammation of the testicle has been for sometime generally known, but from some cause the practice is not so extensively followed as we should be led to expect from the excellent consequences which have resulted from its employment. The fear of producing such an aggravation of the sufferings of the patient, as would counterbalance any good effect which this mode of treatment may exercise on the disease, has been made an excuse for not employing it; and some have argued that where a little pressure increases the pain and thus augments the sufferings of the patient, the employment of constant and firm pressure must necessarily do a proportionate degree of harm. But experience tells us this is not the case, and although the remedy seems severe, it in reality is not so, for it greatly alleviates pain, while at the same time it subdues the disease. I believe that if this mode of treatment were more generally followed, we should find that the number of cases with chronic enlargement of the testis would be far less than at present.

It may be asked, what are the advantages which this mode of treatment possesses over others? It will therefore be as well to refer to the methods in general use and point out some of the inconveniences, if not disadvantages which arise from their employment.

Bleeding is seldom useful except when there is much inflammatory fever. *Leeches* have been the favourite

remedy with many, but there is no practitioner who has had recourse to them who does not know, even in cases where they have been most beneficial, how inconvenient their application always must be. In cases of orchitis the great wish of the patient is to keep secret the cause of his illness, and this can scarcely be done where leeches are used. If a few are applied they seldom do much good, and the expense of many often proves an objection to their use.

Purgatives of course are useful in this disease, but they are not of themselves sufficient to effect a cure.

The same may also be said of *narcotics*, and especially of *opium*.

Mercury is frequently administered in large quantities, and we find ptyalism often occurs before any impression is made on the disease. Excepting in very severe cases this remedy is almost as bad as the disease, and it may do harm when gonorrhœa is present, as of course it often is in cases of orchitis.

Emetic tartar is the remedy most commonly employed, and in many cases it subdues the inflammation. Unpleasent as this medicine is when taken in the nauseating doses requisite, it doubtless does a great deal of good in many cases.

The local application of *cold lotions* or *warm fomentations*, will be found beneficial, more especially the latter, with or without the addition of laudanum or aconite. A warm bran poultice with hydrochlorate of ammonia in it is also useful.

With all these, however, one thing is needful,—entire rest, either in bed or on a couch, and it often proves very inconvenient to the patient to be obliged to submit to this necessary restriction.

Suppose then, that the patient after some days treatment with either of the above remedies, is better, and the inflammation has subsided,—is he well? Certainly not. The testis remains enlarged, hard, painful from its weight, and liable on the slightest injury to take on inflammation, and render the patient incapable of attending to his employment for some days more. If it goes on ever so favourably, a long period must elapse before all the enlargement which remains will yield, either to the employment of mercury or iodine, however diligently applied.

I have thought it best to notice the merits and demerits of the remedies usually employed before speaking of the advantages which result from the use of compression. Some time ago Fricke, of Hamburgh, proposed compression of the testicle when the acute stage of orchitis had subsided; and in sub-acute cases of the disease, Ricord, in France, used it also to a great extent, and I believe still continues it. The practice has now found its advocates in many of our hospitals, although it has not come into general use. Mr. Curling, Mr. Acton, and Mr. Langston Parker, have also used it with success; and at the Seaman's Hospital Mr. Busk almost uniformly follows the practice, and with great success. The following cases will show how effectually it acts in arresting the inflammatory process in the different stages of the disease:—

CASE I.

December 16th. J. T. contracted gonorrhœa about a month since; he has never had orchitis before. He yesterday found the testis becoming painful, and it soon swelled to a large size. It has within the last twenty-four hours become of the size of a hen's egg, is extremely painful and tender, and the scrotum is red and inflamed. There is also pain along the cord, general febrile disturbance, and the gonorrhœa continues. Strips of adhesive plaster were firmly applied round the affected testis, and for the first five minutes caused an increase of pain. He soon, however, became easier, and remained so.

18th. The straps having become very loose from the diminished size of the testis, they were removed, and fresh ones firmly applied.

20th. The straps came off; the testis has almost returned to its natural size, and there is but little induration remaining.

CASE II.

July 4th. R. T., aged 22, has had gonorrhœa eleven days. Six days ago the discharge lessened, and four days ago the right testis became inflamed. Has had gonorrhœa, but not orchitis, before. The testis was strapped with soap plaster, and cubebs given internally.

6th. The testis smaller and less painful. Restrapped.

11th. The testis has regained almost its usual size, and there is but little hardness remaining.

CASE III.

June 26th. H. W., aged 20. Gonorrhœa two months. Four days ago the right testis began to swell, and is now the size of a hen's egg; not very tender except when pressed. Never had orchitis before. Strapped with soap plaster, and to have one drachm of cubebs three times a day.

30th. Gonorrhœa cured; testis much smaller, and hardness less.

July 4th. Cured.

CASE IV.

July 15th. E. M., aged 19. Gonorrhœa fourteen days. Orchitis of both sides. Twelve days ago the right testis became swelled, and has gradually increased in size, and is now as large as a goose egg, tender and painful; there is also tenderness and swelling of the cord. The testicle has been large since an attack of orchitis six months ago. Straps of adhesive plaster were applied.

16th. Much smaller and less painful. Restrapped.

24th. Almost well. The left is now swelled and painful.

25th. The left being larger, was strapped.

26th. Left testis better.

31st. Both well except slight induration of the right.

CASE V.

March 28th. J. M., aged 18, fell across an iron bar and injured the left testis, which has been swelled for a week. It is now about the size of a large hen's

egg, not very hard, and of a more oval form than in gonorrhœal orchitis. Strapped with adhesive plaster.

29th. Much better; straps very loose; re-applied.

31st. The testis is become quite soft, and of its natural size.

I would here observe, that this kind of orchitis (from injury,) gets well more speedily than when connected with gonorrhœal inflammation.

CASE VI.

J. D., aged 25, has had more or less gonorrhœa for two years, but no orchitis. Fourteen days ago the right testis became painful and swelled. Straps of adhesive plaster were tightly applied. In three days it was re-strapped, the scrotum, which was previously tense and inflamed, being now flaccid and free from tenderness. The testis after one more application returned to its usual size.

CASE VII.

June 16th. S. C., aged 30. Gonorrhœa one week. Never had orchitis before. Last evening the testis became tender and swelled, after using violent exercise. The urethral discharge is diminished; there is much pain along the cord, which is swelled. Straps of adhesive plaster were applied, and one drachm of cubebs given every six hours.

18th. Better; testis much smaller. Re-strapped; and after this, being quite easy, he walked a good deal. Pain then came on, and the strapping was immediately removed. Hot fomentations were constantly applied, as the pain became very violent. A little tincture of opium gave speedy relief.

19th. The testis less painful. To be supported by a suspensory.

28th. The testis almost well, but some degree of enlargement and hardness remains.

This case shows that if the compression gives pain and is immediately removed, the case goes on well.

The next case is one where I was not called in to see the patient for some time after he was seized with the severe symptoms which supervened; but I do not doubt that if I had seen him at once, and had immediately removed the strapping, the patient would have done as well as Case 7.

CASE VIII.

June 10th. J. F., aged 24. Gonorrhœa fourteen days. Orchitis six days. Testis the size of a duck's egg, very hard and painful; the cord very tender and swelled. Strapped with adhesive plaster.

12th. Better. Re-strapped.

15th. Better. Re-strapped. Walked a great deal. Some hours after the strapping had been applied, great pain came on, with considerable swelling of the cord, tenderness over the lower part of the abdomen, and pain in the loins. Vomiting, a quick feeble pulse, and cold extremities, were the severe symptoms which followed. Stimuli were given, æther and opium; the strapping removed, and hot fomentations constantly applied. He soon became easier, and progressed favourably.

27th. The testis very hard, but free from pain; in other respects well. (This state of the testis has become permanent.)

The above is the most severe case of the kind which will generally be met with; and I have adduced it to show what is the dark side of this mode of treatment. I do not, however, consider the symptoms to have been more severe than in some cases of orchitis where other treatment than strapping has been used; and often a blow on the testicle will cause the same symptoms.

At the time Case 1 applied to me, a neighbour of his came with the same disease; and, thinking it would be a good opportunity to test the different modes of treatment, I ordered him tartar emetic and calomel, with warm fomentations to the part. He got better in about ten days, but was obliged to use the Linimentum Hydrargyri cum Camphora, for some time before the induration and enlargement of the testis gave way.

A brother practitioner called me to see a case of orchitis, arising from a blow. The testis was very soft but of large size. Here leeches, calomel, and tartar emetic, were put in requisition, and after a week the patient was allowed to get up; and in a few weeks after the testis slowly diminished to nearly its natural size. In this case the probability is, that if strapping had been applied, the cure would have taken not more than a week, as in Case 5; but my friend thought the old mode of treatment better than the new. Since then he, as well as others, has been persuaded of the efficacy of compression in such cases.

Having already taken up far more space than I intended, I will finish these remarks by a few observations on the mode of treatment. It will be seen from the above cases, that we may apply the strapping at any time, from a few hours after the disease has appeared, to a fortnight, or even longer. It generally speedily relieves the pain, but some cases there are where, from violent exercise, or, perhaps, idiosyncrasy, the patient cannot bear the pressure. As a general rule, I should say, that if after the first quarter of an hour of the application, the patient should have much pain, and *increasing* in violence, the strapping should be temporarily removed. If the straps be applied uniformly, and tolerably firm, this will seldom be required. Much, of course, depends on the mode in which the operation is performed, for it is not so easily done as may be imagined; and it would be worth while for a surgeon to go some way to see it properly performed, which he will, most probably, at any large hospital. Care should be taken to place the first strip tightly round the cord, immediately above the testicle, and to continue the strips tightly downwards, with perpendicular ones also to give plenty of support. Soap or adhesive plaster is generally used at first; but in more chronic cases, the Emplastrum Hydrargyri cum Ammoniaco may be substituted.

It will generally be found that a few minutes after the strapping is properly applied the pain is relieved. In

a day or two the testis is so much diminished in size that the straps are very loose; they may then be re-applied once, twice, or thrice, according to the state of the case. I have seen a patient in the greatest agony before the application, and in an hour after the straps have been put on he has been able to walk about almost without pain.

The earlier the remedy is applied the less will be the induration remaining after the inflammatory stage has subsided.

Lastly, (and that not of the least consequence to the surgeon,) the patient will be delighted with the safe, speedy, and almost painless recovery from a very unpleasant disease, and will be grateful for the means of relief being used without discovering to his friends the nature of his malady. More especially will he value this simple and easy mode of treatment if he has unfortunately been the subject of the same disease before, and has had to submit to the nausea consequent on the use of emetic tartar, or the salivation caused by the calomel he has taken, as well as to the troublesome application of leeches and fomentations, to say nothing of the loss of time from being obliged to remain in bed or on a couch for days or even weeks.

Crewkerne, January 29, 1847.

ON SIMPLE ACUTE INFLAMMATION OF THE MEMBRANES OF THE BRAIN IN INFANTS.

By Dr. Rilliet, of Geneva.

(Translated for the Provincial Medical and Surgical Journal.)

I. Preliminary Observations.

A great number of practitioners, even in the present day, confound all the acute cerebral affections of infancy under the term *acute hydrocephalus*, or *tubercular meningitis*; and the error has continued, although many attempts to introduce a more strict pathology have been made, even as long since as the end of the last century.

Thus Hopfengartner, who wrote in 1802, has distinguished meningitis from acute hydrocephalus, and it is evident from the tenor of his observations, that under the former term he alludes to the same form of the disease which it is our object to illustrate in the present communication. "From the very onset of the disease," he observes, "and without any precursory symptoms, the children complain of pains in the head and abdomen; on the second day they keep their bed, and the disease proceeds without those remissions which we notice in acute hydrocephalus. The patients are dull, the eyelids close convulsively; the teeth are fixed, and deglutition is difficult. Constipation is not so obstinate as in hydrocephalus. There is in general little or no vomiting and the pulse is small and slow. Coma supervenes much more rapidly than in hydrocephalus. The patient usually dies about the fifth or sixth day. After death the membranes are found to be inflamed throughout their whole extent."

This description evidently refers to acute meningitis but the author has committed an error in stating that vomiting is absent, and that the pulse is feeble and slow; on the contrary, vomiting is very generally present, and the pulse though feeble, is not slow.

Coindet, while he admits that hydrocephalus is the result of a peculiar inflammation of the lining membrane of the ventricles, establishes a distinction between phrenitis and dropsy of the ventricles.

Matthey also separates the disease which he terms *hydro-meningitis*, from the water on the brain which follows scarlatina, and also from sub-acute hydrocephalus. This latter variety is that described by Whytt and corresponds to the tubercular meningitis of recent writers. The hydro-meningitis of Matthey offers on the contrary a close analogy with the disease in question Its characters as stated by Matthey are as follows:— "More or less headache, sickness, spasmodic movements of the limbs, brilliancy of the eyes, quiet delirium, contraction of the pupils, quick and small pulse, coma. After death, gelatinous effusion on the surface of the brain, seldom in the ventricles."

Jahn (*Analekten über Kinderkrankheiten*, 1835,) describes a form of disease similar to our acute meningitis under the denomination of *idiopathic encephalitis*. It is characterized by intense fever, with quick breathing, thirst, great susceptibility to light and noise, brilliancy of the eyes, frequent vomiting, obstinate costiveness, &c. The anatomical characters, as stated by the author, are:—

1. Injection of the brain and its membranes.
2. Induration of the cerebral substance.
3. Effusion of a greenish lymph in the anfractuosities of the brain, and along the course of the vessels.
4. Absence of serous effusion in the ventricles.

Evanson and Maunsel have also distinguished arachnitis of the convexity of the brain, from inflammation of the membranes at the base, and hydrocephalus. They observe:—"Infants are not exempt from arachnitis of the convexity of the brain, although this form of inflammation is less common than the preceding, (hydrocephalus and inflammation of the base.)" But we need not multiply quotations; those already adduced suffice to demonstrate that several writers have endeavoured to distinguish hydrocephalus from acute inflammation of the nervous centres.

From the time that the term hydrocephalus was exchanged for that of *meningitis*, confusion was re-established,—a confusion which was increased by the terminology. It was rational enough to distinguish hydrocephalus from meningitis; but what good could arise from making two forms of meningitis? Those who had written of the disease under this term, as Golis, Senn, Charpentier, &c., confounded both forms under the same description; but others, as Parent and Martinet, at once separated inflammation of the base from that of the convexity of the brain, and recognized the fact, that in infants the former was a far more common affection than the latter.

From the period at which the writings of MM. Papavoine and Rufz contributed so much to the elucidation of the true nature of acute hydrocephalus, the

epithet *tubercular* was added to the designation *meningitis;* it was thought that more precision was thus introduced into the diagnosis of the disease; but it was not so in truth, for MM. Piet, Green, &c., have almost entirely omitted the mention of simple *meningitis.* Rufz, however, does not deny the existence of this latter affection, though he admits its great comparative rarity; and before him M. Guersent (*Dict. de Méd.*, tom. xix., p. 410,) had distinguished the simple from the tubercular form of meningitis, although he referred to the former, as it appeared in adults, and in an epidemic form.

The first description of *simple acute* meningitis based upon clinical observation is undoubtedly due to the past labours of M. Barthez and myself. But it is strange, that even subsequently to the appearance of our memoir, MM. Deleseur, Barrier, and other talented writers on the diseases of early infancy, have entirely omitted to mention this variety of the disease. M. Deleseur has collected all the acute or subacute cerebral affections of childhood, under the generic term *meningo-encephalitis*, and scarcely even endeavours to distinguish between simple and tubercular meningitis. Trousseau gives the name of *cerebral fever* to all cerebral inflammations indiscriminately. Bouchut and Barrier refer the reader to the tubercular form of the disease, apparently believing that no advantage is to be derived by separating it from simple meningitis.

We do not hesitate to differ entirely from the authors above cited, and to express our belief that their doctrines have been the cause of the greatest confusion. We are far from insisting upon frivolous distinctions, but there are, nevertheless, certain laws which the pathologist cannot transgress, without the risk of falling into error and confusion.

We have already shewn, (*Traité des Maladies des Enfans* tom. iii. p. 518.) and shall again satisfactorily prove, that simple *(franche)* meningitis, and tubercular meningitis differ essentially. Their causes are not alike. They attack children under different circumstances; they have neither the same modes of origin, progress, or termination; their anatomical characters are different, and the treatment likewise is to a certain extent different. If these points are not sufficient to establish their distinction, there is no use in nosological arrangements; our own opinion is that true meningitis is as distinct from tubercular meningitis, as pneumonia is from phthisis pulmonalis.

Before we enter into the more immediate subject of our present communication, it will be useful to make a few observations upon a point upon which we fear that we have been misapprehended in our former writings. In our opinion, meningitis developing itself in a tubercular subject, is always *tubercular* meningitis, whether we find granulations in the pia mater, or whether we do not. Tubercular meningitis, therefore, and the meningitis of the tuberculous, are, to us, one and the same malady, and for these reasons:—

1. In both, the seat of disease is at the base of the brain.

2. Both consist of a thickening of the pia mater with false membranes or purulent exudation.

3. Both are accompanied by effusion into the ventricles, and frequently co-exist with cerebral tubercles.

4. Both co-exist with tubercular deposits in other organs.

On the contrary, in true meningitis, it is the pia mater and arachnoid of the convexity, or of the ventricles, which are inflamed and infiltrated; serous effusion into the ventricles is the exception, and the affection does not coincide with tubercles or granulations, either in the brain or other organs. These differences are so marked, that if the brain of an infant be presented to us, with the fissure of Sylvius filled with adhesive exudation, and the base covered by membranous and purulent deposit, the convexity at the same time being free from inflammation, we do not hesitate to predict that there are most probably also granulations in the membranes and serous effusion into the ventricles, and that tubercles will certainly be found either in the lungs or bronchial glands.

Again, we are able to tell from the nature and number of the tubercles present in the chest or abdomen, what has been the character of the cerebral affection. Thus if we learn that miliary granulations have been found in considerable abundance in the lungs and other organs, we can affirm that the acute symptoms of the head affection have been preceded by precursory symptoms, that the onset of the disease has been insidious, that the inflammation of the membranes was ushered in by vomiting, that there was constipation with but little fever, and that the malady has lasted two or three weeks. On the other hand, if the brain of an infant be exhibited to us, the convexity of which is covered with false membranes or purulent exudation, we do not hesitate to assert that no tubercles will be found either in the membranes of the brain or elsewhere; that the disease has set in suddenly and with violence, with convulsions perhaps, if the infant be very young; with violent headache, constipations, and vomitings if it is of more advanced age; that delirium has been violent, and that the duration of the disease has not been longer than three, four, or six days.

We shall revert to this subject in our article on diagnosis, and shall then enter further into details respecting the differences between the two forms of the disease.

II. Morbid Anatomy.

Great familiarity with pathological anatomy is necessary for the appreciation of the slight lesions which frequently constitute the morbid appearances left by tubercular meningitis; but it is far more easy to recognize the results of true meningitis of the convexity. Scarcely, in fact, is the injected dura mater divided, than a greater or less extent of the convexity of the two hemispheres is seen to be covered with a layer of yellow or yellowish green exudation. The deposit extends also to the internal aspect of the hemispheres, the upper surface of the cerebellum, and sometimes to the base of the brain. A slight examination is sufficient to demonstrate that the deposit consists of liquid pus, and that its seat is always the pia mater, and sometimes also the arachnoid cavity. The products of inflammation deserve to be separately studied in these two situations.

1. *In the arachnoid.*—This membrane, although it contains the products of inflammation, may itself not exhibit any trace of that process; but in general retains its smooth and polished appearance. If life has been prolonged to the sixth or seventh day, the pus loses its fluidity, and acquires such consistence as to resemble a false membrane; in other cases true false membranes are formed in addition to the fluid products. These partake of the yellow colour of the pus,—are thin, soft, and seldom very extensive; they are always easily detached from the serous membrane, unless as is occasionally seen, organization has commenced.

2. *Pia mater.*—Alterations similar to the above are discovered also in the pia mater, especially in patients who have died on the fourth or fifth day. The pus, when liquid, may be made to pass over the surface of the membrane by pressure with the finger, but it subsequently becomes concrete, forming a flat broad layer of variable thickness, and which passes down into the sulci. The membrane appears to be puffed up by the secretion, and is increased both in thickness and tenacity. The deposit of pus is always more copious along the sides of the blood-vessels, and in the interstices of the convolutions, than elsewhere. At the base the pia mater is often quite healthy. Over the surface occupied by the pus, the membrane is finely injected, and is readily detached from the surface of the brain.

3. *Cerebral substance.*—The brain is firm, sometimes preternaturally so. The grey substance is of a normal colour if death has occurred before the fifth day; later it may also be nearly unaltered, but it is more generally of a vivid rose colour, and the medullary portion exhibits numerous bloody points. The most superficial layer of the convolutions is sometimes softened, so that portions of it are removed along with the pia mater. In very young infants, the brain is sometimes softened throughout, an appearance which is probably due to œdema of its tissues. The condition of the brain in subjects who have speedily succumbed, shows plainly that inflammation of the membranes is the initiatory lesion, and the cerebral pulp becomes involved subsequently.

4. *Ventricles.*—As a general rule, the ventricles are found empty, or containing only a teaspoonful or two of purulent serosity. The exception to this occurs in very young infants. In some cases the lining membrane and the plexus choroides exhibit traces of inflammation, being injected and softened, or subsequently pale, but thickened and opaque. The central portions of the brain in some cases, preserve their consistence; in others they are softened, or converted into a diffluent pulp. The latter case chiefly occurs in young infants, in connection with copious serous effusion into the ventricles; but it is occasionally seen without this, and must then be attributed to inflammatory action, and not to maceration, as may be the case when the effusion is in large quantity.

To recapitulate:—The anatomical characters vary according to,—1st, the duration of the malady; 2nd, the age of the patient; 3rd, the seat of the inflammation.

1. In cases which prove fatal before the fifth day, we find the pus fluid or semi-fluid, or false membranes in the arachnoid and pia mater, the latter being vividly injected, but not adherent to the surface of the brain. Later we in general discover only concrete pus or false membranes; the pia mater is less injected, and the surface of the convolutions is sometimes soft and reddened. In some instances the ventricular portion of the arachnoid is inflamed, and the cavity contains a small quantity of purulent serosity, but never pure serum.

2. In very young infants, the brain is often softened universally; the ventricles contain a large quantity of serosity, and there is also occasionally a sub-arachnoid serous effusion.

3. General meningitis is the most common form of the disease; next, meningitis of the convexity; that of the base and ventricles, is much more rare.

(*To be continued.*)

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF WILLIAM SANDS COX, ESQ.

By Peter Hinckes Bird, one of the Resident Medical Officers.

(*Continued from page* 128.)

Case XXV.

FISTULA IN ANO.

William Wilson, aged 38, shoemaker, of full plethoric habit, admitted into the Queen's Hospital, under the care of Mr. Sands Cox, on July 21st, 1846. He states that in June, 1845, he first perceived a small swelling, with circumscribed hardness, on the verge of the anus, it caused him much pain and inconvenience, which gradually increased, so that in September following he was unable to sit down. In December this small swelling "came to a head," which broke and discharged a thin matter; it kept getting worse until January, 1846, when it was about an inch and a half deep; it was then laid open by the medical man attending him. Another formed by the side of it, and it was again laid open, but without success. He states that these openings have bled at times. His health has always been good; no tendeney to phthisis can be traced in the family; his father died of apoplexy; his mother is alive and well; his occupation is a sedentary one; in his early life he was rather "a free liver;" his bowels have always been exceedingly regular; is seldom troubled with cough; has never been subject to hæmorrhoids.

Present state.—There are two fistulous openings, one on the left side, the other on the right side of the anus. The one on the right side has but lately appeared, it is about an inch and a half deep, situated about half an inch from the anus, and communicates with the rectum; the other, which has been present since last September, is situated on the verge of the anus, and is

rather deeper than the former, and also communicates with the rectum; it discharges a thickish matter; he cannot sit upright on a hard bench; bowels reported regular; appetite good; tongue rather coated; pulse natural. It has been dressed lately with dry lint; the margins of the openings appear red and inflamed. Ordered to have a poultice applied.

24th. Much the same; the openings discharge freely into the poultice.

August 5th. Both sinuses were laid open this morning by Mr. Cox, a silver director being introduced into the sinuses, and then into the rectum, through the internal opening. The director being bent, all the soft parts lying over it were divided by a sharp-pointed curved bistoury. He lost a small quantity of blood, but bore the operation well. Ordered to have it dressed from the bottom with dry lint.

12th. The openings are healing up, they look healthy; general health good; bowels open.

20th. The openings are not so deep, have an healthy appearance; bowels regular.

September 1st. Improving rapidly.

16th. Quite well. Discharged cured.

The preceding case presents an instance of complete fistula in the anus, which is not such a frequent form of this disease as that in which the abscess has only an external opening, (blind external fistula,) and does not perforate the rectum at all, from which, indeed, the matter is more or less distant.

Abscesses near the rectum happen with particular frequency in persons who are habitually costive, and according to Sir B. Brodie, in those who have been troubled with piles; they have also been produced by foreign bodies penetrating through the mucous membrane of the bowel and sphincter muscle into the cellular tissue. The pathology of these cases of complete fistula is exceedingly interesting; an indurated stool, a foreign body (a fish-bone or an apple-pip, for instance,) in its course through the rectum, produces solution of the continuity of the coats of the rectum, and into this small wound either the fæces or the foreign body enters, and excites inflammation, followed by suppuration, which is kept up by the presence of the foreign body; this gradually progresses until a fistula is formed by the abscess breaking on the integument on the verge of the anus. According to M. Ribes,* when the abscess communicates with the bowel, the orifice is *always* within five or six lines above the junction of the internal membrane of the bowel with the external skin. Abscesses near the rectum have a great tendency to form fistulous openings.

Sir B. Brodie* admits with Pott that abscesses near the rectum after discharging themselves sometimes heal up like others. This, however, he considers as an exception to the general rule.

In the majority of cases, if nothing be done, the opening will continue, sometimes discharging little, sometimes much, or it will discharge and break alternately. The reason why abscesses near the rectum heal up less frequently than others, is referred by Sir B. Brodie to the sinus or passage for the matter running through the sphincter ani muscle; this muscle is constantly in motion, contracting and dilating, and consequently there is not the repose which is necessary for the cure of the abscess.

Abscess near the rectum frequently occurs in patients who are labouring under abscesses or tubercles in the lungs. Hence Sir B. Brodie properly recommends surgeons, before they operate on a patient for fistula, to ascertain whether the lungs are sound. He observes, "Persons with diseased liver and other visceral diseases, are also liable to the formation of these abscesses. The distinction of these cases from others which occur in otherwise healthy subjects, is very important, inasmuch as the practice which is proper in the one case is quite improper in the other." He adds, that if the patient labours under visceral disease, it is seldom that the abscess will heal, but if it should, the visceral disease will make increased progress, and the patient will die sooner if the operation be performed than if it were let alone.

In this operation the intention is to divide the intestine from the verge of the anus, up as high as the top of the hollow in which the matter was formed, so that the two cavities of the gut and fistula are made into one, and a firm and lasting cure is obtained, instead of a hollow or sinuous sore, which serves for the lodgement of matter. The operation is effectual, however, on another principle—viz., the fibres of the sphincter between the abscess and the bowel are divided, and the sphincter muscle being thus set at liberty, there is not only a free and ready escape for the matter, but the action of the muscle, which prevents the healing of the abscess, is put an end to. In these cases every sinus must be laid open. The dressings should be soft, easy, and light, the whole intent of these being to produce such suppuration as may soften the parts, and bring them into a state fit for healing. Sir B. Brodie states that it is chiefly in consequence of too much lint in dressing that farther operations are so frequently wanted before the cure is completed. The daily dressing should be repeated until the cut surfaces are cicatrized, but no longer. The cicatrization of the bottom of the sinus will be completed better without the dressing than with it.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, MARCH 24, 1847.

It has been well remarked by Dugald Stewart, that "the chief part of a philosopher's life must be spent in unlearning the errors of the crowd." The remark applies with peculiar force to the medical philosopher, and every thinking practitioner cannot but have observed that in the taken-for-granted effect of remedies, there is nearly as much to unlearn as to

learn; while the advancement of medical science must ultimately depend upon the judgment exercised by its professors, as well in the detecting of errors, as in tracing effects to their real causes.

The leading principles of treatment now generally admitted by the profession are tried principles, not to be set aside by the vagaries of weak minds, nor the superficial objections of half-educated innovators. Our present object is not to bring these principles for a thousandth time under critical review, but to throw out a few hints which may assist in the more rigid and vigilant application of them to particular cases. There are few, if any, among us who are sufficiently alive to the danger of drawing false practical conclusions from the phenomena constantly passing under observation. The science of medicine is so complicated,—the ever-varying phases of disease are under the influence of so many contingencies of climate, temperament, diet, regimen, mental excitement, and other circumstances, that he must possess a mind of no common order, who can grasp and weigh them all. It is much, that in the midst of so many difficulties, we should have attained to so much harmony, as regards great principles; and yet more, that for a century, at the least, all the great, the learned, and the enlightened among us, have, through various channels, and sometimes in spite of opposing theories, deduced from these principles, the same practical lessons.

The general agreement of leading minds on leading points, though not amounting to absolute authority in medical matters, may be regarded as light in the darkness,—as lucid points which, without prostrating the judgment, may serve to direct the researches of those enquiring after truth. Not one of these accredited principles can, it is true, be established as infallibly correct; yet no sensible man would feel himself justified in treating them with contempt, or rejecting them without years of patient and laborious examination. Many of them have passed unscathed, if not unchallenged, from the days of Hippocrates till now; and a flippant disturber of these settled points must be very ready with his pleadings, if he would escape universal contempt. Nevertheless, the field is always open; diseases still exist, terrible and fatal, which defy the best resources of our art; and cases of daily occurrence, not formidable in their original character, become serious, and sometimes fatal, in their issue, baffling the skill and disappointing the diagnosis of our most careful practitioners. Learners, and docile learners too, the members of our toilsome and intricate craft, must ever remain: dogmatism ill becomes those who have yet so much to learn.

A proposal for the investigation of subjects of inquiry on which information is required, was some months back suggested by an intelligent correspondent,* which, if cordially and generally responded to, *must* effect something. On the other hand, should any considerable number of the members refuse their co-operation, on the ground that the object sought to be attained cannot be fully and satisfactorily carried out, then the proposal referred to, or any other requiring the co-operation of numbers, must partially at least fail. In the hope that members will feel themselves called upon to lend their aid to a work of this nature, which, if it succeeds, cannot fail to advance our individual practical knowledge, a series of questions will shortly be addressed to each member, touching his professional experience on various practical subjects. It is not intended to ask for opinions, much as in some quarters they may be entitled to respect. It is to be feared that some of us may have set down in our own minds as facts or truths, inferences only, not always perhaps correctly drawn from facts, or drawn from appearances, mistaken for facts,—in both cases fallacious and erroneous. It is proposed, therefore, to ask for facts,—facts carefully observed, but wholly unincumbered with inferences; and it is scarcely necessary to remark, that a record of naked, well-attested facts, arranged in an orderly method, must be of some private service to each individual member, even if they be collected only by himself; but when multiplied by the whole number of our members, who among us would not hail the statistical result as a guide to his own practice, as a corrective of any erroneous opinions formed on too narrow a scale of observation, and, to the younger members especially, as a remedy for early prepossessions or prejudices.

With *opinions* we have no wish to interefere: we have no right to challenge them. Fallible ourselves, we must in this respect bear with each others errors and infirmities; but as members of a liberal profession, we claim a right to a reciprocal communication of physical facts. They are our common property: their value to each one of us becomes enhanced by their publication for the use of all. Unlike the pretended arcana of the empiric, the discoveries of the qualified practitioner enrich their possessor in proportion to the extent wherewith he shares them with his brethren. The genuine physician has no reserves,—no mysteries, no dealings with occult influences. He rejoices with others in their success in the alleviation of human suffering. He knows how to "give

* *Provincial Medical and Surgical Journal*, July 8th, 1846, p. 311.

honour to whom honour is due." To him is reserved the high prerogative of trying the gold in the fire and circulating the pure metal for the general good. To the honour of the medical profession be it spoken, neither the fame nor the emolument of its members is secured by "Royal letters patent." Their midnight oil burns for their brethren as for themselves, and through them for all mankind. In them is literally fulfilled the proverb,—"there is that scattereth and yet increaseth"

That the fountains of our science may be rendered yet more pure, and better adapted to the dignified purposes of our art, the following observations are submitted to the consideration of the readers of the *Provincial Journal*:—

1. The effects resulting from the medical treatment of disease seldom or never admit of absolute demonstration.

2. Nevertheless, the highest degree of probability which the subject will admit of, may be fairly taken for demonstration, and acted upon with confidence.

3. The barest probability must occasionally determine our practice, when better evidence is wanting; but extreme vigilance should be exercised.

4. Established opinions are worthy of respect, not only as the opinions of the most distinguished men, but as having become established, in a high degree of probability, on the best grounds.

5. The most judicious medical treatment is founded generally on established opinions, and for this reason it usually comprises a variety of agents; hence there is little to be learned from it. If it succeed, it is impossible to determine, *from the facts of the case*, to which agent success is chiefly due; if it fail, the cause of failure is equally obscure. This remark applies in some degree to nineteen out of every twenty cases which come under treatment. Hence the slow progress of medical science. We learn nothing with certainty from the great mass of our cases, especially if our practice be careful and discreet.

6. It follows (from proposition 5,) that those diseases afford the best opportunities for increasing our therapeutical knowledge, which are generally held to be intractable or incurable, inasmuch as established treatment having failed, we are not bound to put it into practice. The learner also derives a farther advantage from these cases; the *vis-medicatrix naturæ* being inert or insufficient, recovery, when it occurs, may fairly be attributed to medical agency. Here also some new method of treatment, founded upon analogy, may fairly be tried.

7. The new method should be simple and defined, consisting, if possible, of one remedy alone, used under circumstances favourable for its exhibition, and so administered, as to show—1st, the effects of an over-dose; 2nd, the state of the disease under this over-dose; 3rd, the state of the disease under the maximum dose; 4th, the *actual operation* of the remedy on the morbid action, proved by its recession under the medicine, and its advance under its discontinuance. These experiments (the results having been ascertained in one case, or under one set of conditions,) should be tried under every possible variety of circumstances, with and without other adjuvants;—in every variety of cases, acute, chronic, recent, advanced;—at all ages, and in either sex;—in hospitals, in dispensaries, and in private practice;—in cities, in the country;—in inland districts, and at the sea side;—in damp situations, and in dry;—in winter, and in summer;—in spring, and in autumn. The symptoms in each case should be carefully noted while the patient is under examination, and as carefully entered in a well-adjusted, well-indexed notebook, ready for reference at all times.

8. If every intelligent and observant practitioner were to try one remedy on the plan above detailed, so far as his position rendered it possible, and during his whole life direct his especial attention to the operation of that remedy in any incurable disease, or class of diseases, to which it might on any rational analogy appear adapted, his life would yet be too short to work the problem fully, and he would still leave much to be accomplished; but the results of his own researches would necessarily be very instructive, and an instalment of no mean value would be paid into the treasury of science. The separate facts deduced from his experience, when duly arranged and digested, would produce in his own mind results not absolutely demonstrative possibly, but yet so conclusive as to approach as near to the confines of fixed and settled truth as is attainable in a mixed and applied science like that of medicine.

In conclusion we would commend this method to the consideration of the members of the Provincial Association,—to the sober-minded, quiet, thoughtful, practitioners of the provinces,—and especially to those who wish to distinguish themselves by really benefitting their fellow-men.

Review.

A Manual of the Principles and Practice of Ophthalmic Medicine and Surgery. By T. Wharton Jones, F.R.S. London: Churchill. Fcap. 8vo., pp. 570.

It is curious to refer to the older writers upon ophthalmic surgery, and to see what strange treatment was adopted by them. A favourite remedy, even during the early part of the last century, was the placing of

"a lowse" in the eye, which, as Richard Banister, Master in Chirurgery, quaintly observes, "tickleth and pricketh, so that it maketh the eye moist and rumaticke, and quickeneth the spirits." We may doubt, however, whether it added much to the comfort of the patient so favoured. Others scrubbed the conjunctiva with the sharp beards of rye in cases of ophthalmia. And friction on the cornea with a gold ring was considered a sovereign remedy for opacity. We may reasonably suppose that this was a frequent consequence of the two first-mentioned applications; and pounded glass blown into the eye enjoyed a high reputation for rubbing it off again. The wonder is that any eyes recovered. Our forefathers must have had but an indifferent time of it when they laboured under the double affliction of bad eyes, and worse oculists. Sore must have been the struggle on the part of persecuted nature, to resist the combined onslaught of disease and the doctors. Happily for suffering humanity, a great change has been wrought of late years. Just and enlightened views gradually succeeded to profound ignorance, and eye-diseases were rescued from the hands of those "proud quack-salving mountebanks" (as Banister calls them,) under whose dominion they had been so long suffered to remain. It was reserved, however, for the present century to see ophthalmic surgery assume its legitimate position in medical science; a fact of more importance than may at first sight appear.

It is not only the sufferers, but the public at large, who have a direct interest in the prevention of blindness. Great as this calamity is to the individual whose circumstances enable him to bring within his reach the luxuries of wealth, and who can soothe his affliction by intellectual resources, bodily enjoyments, or agreeable society, the misfortune is far heavier when it befalls the poor man, upon whose exertions a family are dependent for their bread. In that case poverty soon aggravates the misery of darkness; the means of subsistence being withdrawn, the sufferer and his family are thrown upon casual charity for support, or are driven to that last resource of the wretched—the workhouse. It is then of the highest importance that diseases of the eye should have brought to bear upon them all the advantages that science, observation, and experience can afford. It is gratifying to observe that the medical profession generally is becoming daily more familiar with a class of diseases yielding in importance to none, but until recently we fear too much neglected.

The object of the author of the volume before us, has been, (he informs us,) "to produce a work on the diseases of the eye, which should serve at once as a text-book for students, and as a book of reference for practitioners." He commences very properly, by giving directions for examining the eye and its appendages, and for the employment of remedial applications. After a description of the phenomena of inflammation in general, ophthalmic inflammations in particular are considered. Mr. Jones divides the ophthalmiæ into orders and genera as follows:—

Order I. *Ophthalmia externa*, comprehends conjunctivitis, sclerotitis, corneitis, and compound external ophthalmia—that is, the catarrhal form modified by struma and rheumatism.

Order II. *Ophthalmia interna anterior*, comprises aquo-capsulitis, iritis, and crystallino-capsulitis anterior.

Orders III. and IV. embrace ophthalmia interna posterior, and panophthalmitis, (inflammation of the globe.)

When upon the subject of choroiditis, the author remarks, that "the anatomical characters of the inflammations of the choroid and retina cannot be directly observed during life; even the external redness of congestion proper to them cannot be seen, for, different from the structures hitherto considered, the blood-vessels of those under notice enter the eyeball at its posterior part."

The prognosis given of gonorrhœal ophthalmia, that formidable disease requiring such bold and energetic treatment, is, "until, with a cornea safe, or at least not much ulcerated, the disease is on the decline, which is known by the subsidence of the swelling of the eyelids and of the chemosis, with diminution of the discharge, the prognosis must be extremely unfavourable. The eye may be destroyed in forty-eight hours, from the commencement of the disease."

To the account of the ophthalmiæ, succeeds the description of the various morbid states of the eye consequent upon them; as granular conjunctiva, staphyloma, &c. The third chapter is devoted to dropsies, tumours, cancer, &c., of the eye-ball; and to the consideration of cataract and artificial pupil. The various operations are fully discussed, and the descriptions illustrated by numerous wood-cuts; indeed expense has not been spared in introducing figures whenever the subject could be elucidated by them. Mr. Jones then treats in succession, of optical defects, amaurotic affections, and strabismus. Diseases of the eyelids, of the lachrymal organs, and of the orbit, follow in order; and the conclusion of the volume is devoted to injuries of the eye and its appendages.

When treating of diseases of the eyelids, the author thus describes a morbid condition of those appendages, comparatively harmless if let alone, but often roused into malignant activity by injudicious interference, and irritating applications. "Scirrhoid callosity of the eyelids, a hard tuberculated warty-like degeneration of the whole thickness of the eyelid, commonly the lower, at the tarsal border to a greater or less extent, traversed by varicose vessels, and ending in ulceration, sometimes occurs, especially in old people. Though resembling, it is not of the nature of scirrhus."

We may here remark, that much caution ought to

be exercised before meddling with the indolent warty growths often found upon the faces of elderly people. If let alone they are perfectly innocuous; but several instances have fallen under our observation of very serious mischief resulting from the application of caustics. The growth has returned again and again, after repeated cauterization, each time worse than before, until that which was a harmless pimple has been converted into an extensive, unsightly, and intractable disease.

Our opinion of the work before us is, that it bears evidence of extensive reading, and considerable research; but the author must forgive us if we object to the *style*, as being unusually hard and involved. The complication of some of the sentences renders close attention necessary to understand their meaning. The wear and tear of body and mind, inseparable from extensive practice—especially country practice—often disinclines medical men to labourious study; to them it is no trifling recommendation that a book should be written in clear, perspicuous, and readable language.

"Est brevitate opus, ut currat sententia, neu se
"Impediat verbis lassas onerantibus aures."—

The style we would prefer is perfectly compatible with scientific information; it materially enhances the interest of a book, and has imparted additional grace to the productions of some of the ablest writers of the age.

Proceedings of Societies.

SHEFFIELD MEDICAL SOCIETY.

Sixth Session.—Eighth Meeting, January 7th, 1847.
The President, Mr. TURTON, in the chair.

PNEUMONIA: DISEASED KIDNEY.

Mr. Law exhibited the left lung and kidneys of a patient, aged 38, who had died a few hours after admission into the Infirmary, seven weeks after delivery. The lung was a well-marked specimen of pneumonia in its third stage, the infiltration of pus being general, with several small collections in the form of vomicæ. A portion of the right lung was also found hepatized. The kidneys viewed together presented a singular appearance, one being natural in appearance, the other extremely pale and exsanguine. It is to be regretted that no history could be obtained with respect to this woman.

TUBERCULAR PHTHISIS.

Dr. Branson exhibited the lower portion of the ileum and upper part of the left lung of a table-knife cutler, aged 56, who was admitted into the Infirmary in the last stage of phthisis; the patient had also suffered from long-continued diarrhœa. Peyer's glands were extensively and deeply ulcerated. The apex of the left lung was occupied with a mass of India-rubber-like substance, very similar to that frequently met with in the lungs of grinders; this mass was studded with tubercles, and in the centre of it was a small tubercular cavity; the right lung afforded a good specimen of tubercular infiltration.

Mr. Law exhibited Ellis's apparatus for the treatment of fractures of the clavicle.

A gentleman introduced by the President exhibited specimens of Markwick's *piline* and *spongio-piline*, as a substitute for poultices.

CARCINOMA OF THE HEART.

Mr. Law read a paper on the habitudes of cancer, in which he detailed the subjoined case of scirrhous heart:—All the known habitudes of cancer were stated, and an opinion expressed, that the teeth were never attacked by it; the writer referring to a case in which a large portion of each jaw was destroyed, and the teeth escaped. As the disease destroyed the alveolar processes, the teeth fell out, or they were found imbedded in the soft parts, but they were perfectly sound. This was a strong argument against the doctrine still held by some that the teeth possess vitality.

H. G———, aged 39, of Harvest Lane, a table-blade grinder, was admitted an out-patient of the Infirmary, October 16th, 1846, and an in-patient on the 13th November. He died in an extremely anœmic condition, apparently of apnœa, on the 2nd December. His height was five feet four inches. When in health he weighed eight stone four pounds, and had a fair and clear complexion. He married in his 22nd year. His father dying, and his mother abandoning him in his seventh year, he was brought up as a parish apprentice, and experienced great hardships, being badly fed and clothed, and exposed to cold during the winter days and nights. From his 21st to his 32nd or 33rd year he got drunk nearly every night; but during the last seven years he was a teetotaller, and kept his pledge. His health, however, was pretty good until his last year, at the commencement of which he had an abscess behind the right ear. This opened naturally and soon healed, but he was never well afterwards, always complaining of pain in his chest, particularly the left side of the chest, and head; he soon became unable to work at his trade, and was latterly employed as a table-knife buffer, having laid aside the more laborious occupation of grinding. The medical history of his family is not known to his widow, she could not say that any of his relatives had had cancer. For the last three months the pain in the head and left side of the chest was worse, and he seemed quite unable to lie on his left side. He complained very much of his tongue, and refused all food requiring to be chewed. He had very distressing dyspnœa, which was least troublesome when he lay on his right side; and he was troubled with a constant tickling cough, with scanty expectoration. When he became an in-patient there was scirrhous ulceration of the tongue, he articulated very imperfectly, and the countenance was in the highest degree expressive of the cancerous diathesis.

It was easy to surmise that the dyspnœa depended on a mechanical cause, and the condition of the tongue, with the expression of the countenance, left little room for doubting that this mechanical cause was a scirrhous tumour or tumours, compressing the bronchi. It was obvious that death would speedily terminate his sufferings, and it was judged right to do nothing in the way of treatment farther than to administer stimulants and

liquid nutriment, with a view of sustaining the rapidly failing strength, and opium, with the view of allaying pain. It is much to be regretted that the chest of this patient was not examined with the stethoscope.

The heart was small, and weighed seven ounces and a half; there was very great concentric hypertrophy of the left ventricle, the cavity being only large enough to contain the thumb, while the walls were nearly an inch thick; the aorta was small proportionately to the size of the ventricle; the right ventricle also was small; the valves, especially the mitral, were somewhat thicker and less transparent than natural, but there seemed to be no reason to doubt that they had performed their function to the last. In the anterior wall of the right ventricle, near the base of the organ, there existed a large hard inelastic tumour, of the form of a flattened sphere, an inch and a half in diameter, and three quarters of an inch thick at the centre; the tumour next in size was as large as a field-bean, and situated in the anterior part of the wall of the left ventricle, also near the base of that organ; there were several smaller scirrhous masses, some connected with the left, and others with the right ventricle. In the apex of the right lung was a large scirrhous tumour, the size of a hen's egg; the lower lobe of the left lung presented the infiltrated form of the disease, in which form it also existed in the right clavicle, which was almost divided near the sternum by the cancerous deposition. The bronchial glands were one mass of scirrhus, and had, it was conjectured, occasioned the fatal apnœa. The autopsia was made under unusual difficulties, permission being given only for an examination of the upper part of the chest. The abdominal viscera, however, inspected by cutting through the diaphragm, were found healthy. The brain and spinal cord were not examined. The lungs and clavicle exhibited scirrhous formation, and with the heart, were exhibited to the Society.

With respect to the cause of extraordinary development of cancer in this patient, Mr. Law advanced nothing demanding particular attention; he left his hearers to form their own opinion as to the effect on the constitution of the man, of that sudden and total abandonment of intoxicating drinks, which was made in his 32nd or 33rd year, and persisted in to the last, for taking brandy in the way of medicine was no violation of his pledge. Mr. Law considered it idle to talk of the extension of the cancerous diathesis to the heart; but supposing this diathesis to have formed an original part of his constitution, then the whole life of the patient, as herein detailed, may have been a powerful exciting cause of the disease, as indeed it might have been of any other lesion. When the reader discovered the scirrhous heart, he had an impression that few medical practitioners had ever seen this organ similarly affected; he had since conversed with many medical gentlemen, and could not find that a similar case had occurred in Sheffield; but as the condition of the heart of H. G——— would never have been known without the *post-mortem* examination, so it is evident, since the majority of dead bodies are never examined, that cases may have occurred which were never detected.

Dr. Walshe says, (page 368,) "Cancer of the heart is not so excessively uncommon as is generally imagined; six of 8289 deaths are ascribed in the Paris registers to this organ, a higher quota than that supplied by several structures in which cancerous disease is familiarly known. I have had no great difficulty in bringing together twenty five cases, scattered through various works and journals; but the almost invariable deficiency of clinical narratives is deeply to be lamented." Fourteen of Dr. Walshe's twenty-five cases were examples of encephaloid, and perhaps only four of scirrhus. This point is not very clear. At page 370 Dr. Walshe says that cancer is but little disposed to attack the heart. The systematic works on medicine and surgery are for the most part silent respecting cancer of the heart, and neither Dr. Walshe nor Dr. Latham mention it. In Dr. Fletcher's "Elements of General Pathology," edited by Drs. Drysdale and Russell, p. 231, the following passage occurs:—"According to Meckle, a true scirrhus always begins in mucous or sebaceous follicles. Exceptions however, occur, although these perhaps are more frequently merely indurations; however, they are explicitly stated to arise in the heart by Cruveilhier, Ollivier, Bayle, and Andral. They occur chiefly on the right side in the membrane which is continued from the veins." In the case of H. G——— the scirrhus was developed in the muscular substance, and was unconnected either with mucous follicles, or with the membrane which is continued from the veins, although the endocardium, it should have been stated, was raised into a pouch on the right side of the heart, directly under the largest of the scirrhous tumours. The pouch was filled with cheesy-looking matter.

Dr. Hope, at page 355, cites cases of cancer of the heart. He does not appear to have seen the disease, except one case of cerebriform cancer, and nothing can be more meagre than his statements on the subject. Dr. C. J. B. Williams, on "Diseases of the Chest," p. 279, says,—"Malignant disease rarely affects the heart. A few instances are recorded by French authors. I have seen the septum to a great extent converted into a tough medullary substance, with a nodulated surface, which seemed to me of a carcinomatous character. The patient had died suddenly." Dr. Swaine, in a note to his translation of Hasse, says,—"I have myself met with ulcerous medullary fungus, occupying the septum which divides the two auricles, and discharging into the left auricle." According to Bouillaud, M. Carcasonne (Mem. de la Societé Royale de Médecine, 1777 to 1778,) was the first to describe cancer of the heart, though there is a case described in the same work for the preceding year, (1776.) One of these is alluded to by Dr. Hope; but Bouillaud, without assigning reason, is inclined to doubt their accuracy. Recamier, Rullier, Cruveilhier, Ferras, Andral, Bayle, Trelah, Velpeau, Laennec, Ollivier, Billard, Bouillaud, and Bertin, have all described cancer of the heart. In Velpeau's case the heart contained a dozen cancerous masses of different sizes, the largest not exceeding the size of a pigeon's egg. Billard's patient was only three days old. The case is given in his work on new-born infants. Only two cases occur in Dr. Hodgkin's

"Catalogue of Guy's Hospital Museum," (1829.) In the new catalogue of the St. Bartholomew's Hospital museum, there are three cases of medullary cancer of the heart, two of melanosis, and none of scirrhus. The *Lancet* for November 21st, 1846, contains the report of a meeting of the Royal Medical and Chirurgical Society, held November 10th. At this meeting two remarkable cases of encephaloid disease of the heart were detailed at length by Mr. Prescot Hewett. In one of these cases, the tumour proceeding from the appendix filled the right auricle, and extended into the ventricle. In the other case, the auricular surface of the mitral valve was extensively covered by a soft deposit, which, examined by the microscope, presented some large nucleated, but no caudate, cells. This patient, a female, fifty-nine years of age, was admitted for encephaloid of the breast, which was not removed; the other, for encephaloid of the foot, (resembling the disease of the heart,) for which his leg was amputated.

It appears probable that cancer never primarily affects the heart; at all events, the disease is very seldom limited to that organ. Dr. Walshe has collected only two cases of solitary cancer of the heart, and he thinks that one of them is open to objection. It may occur in association with cancer of any other part. Hasse (Pathological Anatomy, p. 107, by Swaine,) has this passage:—"A few scattered examples of medullary tumours, found growing with a pedicle from the inner surface of the heart, without any co-existing trace of disease elsewhere, shows that that organ may be the primary seat of the morbid development."

Mr. Law, in conclusion, acknowledged his obligations to Mr. Overend, who had given him the opportunity of bringing the case before the Society. In the discussion which ensued, Mr. Nicholson stated, that when a pupil, he saw in the hospital practice of Sir Astley Cooper, a scirrhous heart, taken from the body of a female, both of whose breasts and one of the eyes had been removed for scirrhus. Sir Astley had no doubt about the scirrhous character of the heart-disease.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

January 4th.

PHTHISIS.

At this meeting, M. Bureaud Riofrey read a paper on the treatment of phthisis by exercising the lungs, and the exhibition of fatty substances. His arguments are founded upon the extraneous nature of tubercle, and the antagonistic characters of fat. The regulated exercise of the breathing is supposed by him to be capable of favouring the expulsion of the foreign matter.

Three other memoirs on comparative physiology, of insignificant interest, were also presented.

January 11th.

NERVES OF THE PERITONEUM.

This evening was occupied by the reading of a letter from M. Vrolik with the description of the nerves of the peritoneum of the whale, the tendency of which is mainly to support the views of M. Bourgery respecting the distribution of nervous filaments to the human peritoneum.

January 18th.

FUNCTIONS OF THE PNEUMOGASTRIC NERVES.

M. Sandras read a memoir, the joint labour of himself and M. Bouchardat, the object of which was to determine the importance of the pneumogastric nerves in the process of digestion. With this view they instituted a series of researches to ascertain :—

1. The manner of dying in animals in whom the pneumogastric nerves have been divided.
2. The function of these nerves in digestion.
3. Their function as regards the production and absorption of chyle.
4. Their function in reference to the digestion of fecula.

As a secondary point they wished to determine whether, and how, the divided nerves are capable of uniting. Their experiments are arranged in two series, one having reference to the phenomenon attendant upon the entire section of the nerves; the second taking account of the results of successive divisions of the nerves. The simultaneous section of both nerves gives rise to phenomena which establish the following facts :—

1. Rabbits and dogs do not die immediately when a piece of the nerve of twenty millimeters in length is removed opposite the cricoid cartilage. These animals may survive several days without great distress.
2. In animals thus operated upon the food passes the cardia in small quantity or not at all.
3. In dogs, although digestion has commenced, it is arrested by division of the nerves.
4. The digestion of amylaceous matters in the intestines is not materially interfered with.
5. These nerves are essentially motor.

The second class of experiments proves :—

1. That dogs survive four or six days after the section of the second nerve, and sixteen or seventeen after that of the first, when the two nerves are divided at different times.
2. That animals thus treated eat with avidity, but do not exhibit an unintelligent voracity. They cease to feed as soon as the œsophagus becomes distended.

To recapitulate, the authors consider that they have established that the *movements of the stomach and digestion* are interrupted by the simultaneous section of both nerves in the neck; and that *intestinal digestion* continues in spite of this division

A letter on the existence of creatine in the organism was read by M. Liebig.

SULPHURIC ÆTHER.

The priority of the discovery of the effects of sulphuric æther was claimed by M. Ducros.

In answer to a question relative to the effect of the inhalation of æther upon the progress of cases operated upon, M. Velpeau said that he had not heard of any serious accident; he had once known some headache remain for a period of twenty-four hours. Several members related their failures to produce insensibility a fact readily accounted for by the clumsy apparatus they had made use of.

ANATOMY OF THE PERITONEUM.

M. Pappenheim referred to the communication of M. Vrolik above-mentioned, and alluded to some researches of his own on the same subject. He stated that many of the fibres supposed to be nervous, were in reality partly elastic and partly cellular tissue.

January 25th.

SEA SICKNESS.

M. Pellarin read a memoir on this subject, in which he endeavours to expose the error of the two most generally received opinions of this distressing sickness, viz, that it is due to congestion of the brain; and the other opinion, that it is produced by agitation of the abdominal viscera. The author attributes the malady to the disturbance of the circulation induced by the varied movements of the vessel. This disturbance, so far from producing congestion of the brain, is considered by the author to deprive it of the quantity sufficient for the due maintenance of its functions. Sea sickness, therefore, according to M. Pellarin, depends upon anæmia of the brain. It is combatted by stimulants, and the avoidance as much as possible of the agitation of the vessel.

ÆTHER-INHALATION.

M. Gerdy detailed his own sensations when under the effects of æther. At first he was annoyed by a sense of heat in the larynx and by coughing, but perseverance shortly overcame those effects, and he then perceived a kind of stupefaction, which extended over the entire frame. This was accompanied by an agreeable tingling, and a sense of warmth, with a vibration, such as is communicated by the touch of a body in a state of vibration. His sight was but little affected, but the hearing was more interfered with. From the farther account of his sensations, it would appear that he did not induce entire insensibility.

M. Velpeau, in detailing his farther experience, stated that he regarded the inhalation as a discovery of the highest importance.

M. Robin presented a memoir concerning the mode of action exercised by those substances during life, which after death preserve the body from putrefaction.

February 1st.

ÆTHER-INHALATION.

M. Velpeau detalied a case of fracture of the thigh, the reduction of which was readily affected under æthereal insensibility. He also related several successful cases, including removal of tumours, amputations, &c.

M. Magendie could not partake of the enthusiasm in reference to æther, and in a long speech endeavoured to alarm his hearers by the reports of the evils which might ensue. He ended by designating the process not only as dangerous, but immoral. His objections were justly regarded as absurd.

M. Lallemand enquired whether it was not a fact that the æther-inhalation destroyed for the time the contractility of the muscles; if so, it might lead to much inconvenience in certain operations, the success of which depended upon regular and definite contraction of the muscles after incision.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS.

January 5th, 1847.

OPERATIONS FOR STONE.

After the ordinary business of the Society had been transacted, M. Roux read a report on two memoirs submitted to the academy on the subject of the operations for stone. Of these the memoir of M. Henry consisted of the detail of a case in which the bilateral operation had been performed on a man aged 35, the nucleus of the stone (which was of an immense size,) being a shoemaker's awl. The other from M. Renaud, contains the narrative of four successful cases of lithotomy in children from four to ten years, and of a case of lithotrity in an adult.

In his report on these memoirs, M. Roux took occasion to remark on the great preponderance of stone cases among the lower orders, and the general success of lithotomy in children. He then drew a comparison of the advantages of the operations of lithotomy and lithotrity, deciding in accordance with general opinion that lithotomy is preferable in early age. He likewise considers that it is in exceptional cases only that lithotrity is to be preferred even in the adult.

M. Velpeau also expressed some doubts as to the presumed superiority of lithotrity, in consequence of which it was proposed by M. Amussat, that the question should be formally discussed at a future meeting.

January 12th.

ÆTHER-INHALATION.

On this evening was introduced the interesting subject of the inhalation of æther in surgical operations. M. Malgaigne first related several successful cases, and described the apparatus employed, but at the present time, neither the one nor the other of these are of sufficient importance to be repeated.

M. Velpeau, at this time being unacquainted with the effects of æther, had been afraid to give it a trial.

M. Guibourt and others testified to the innocuity of the agent.

THEORY OF INTERMITTENTS.

M. Piorry again occupied the Society with his theory of intermittent fever, which he expressed in the following aphoristic terms:—

1. A complete accession of fever,—chilliness, heat and sweating,—is a neuropathic action commencing in the abdominal and thoracic plexus of nerves, and especially in the portions belonging to the spleen, liver, and genital organs. This nervous action extends to successive points in the cerebro-spinal system; it eventually reaches the peripheral nerves and gives rise to rigor.

2. Periodic attacks which are few in number, may originate in the renal or the ovarian plexus, the neuropathy thence extending to the splenic plexus and nerves.

3. Quotidian, tertian, and other periodic forms originate in a neuropathy of the splenic plexus.

4. The cause of this neuropathy lies in various lesions of the spleen, as congestion, inflammation, hypertrophy, &c., chiefly in the first of these.

5. The splenic affection is due to marshy exhalations.

6. These exhalations act primarily on the blood, to which they act as a direct poison.

7. The primary action of this deteriorated blood is upon the spleen, in which it produces engorgement and hypertrophy; thence the nervous affection.

8. This affection of the spleen in its turn affects the constitution of the blood, the degeneration of which is seen in the pallor of the skin, general debility, &c.

To this theory M. Rochoux advanced two objections:—

1. The intermittent fever precedes the lesion of the spleen.

2. The fever ceases, though the spleen retains its volume

M. Bouillaud also attacked the theory, and commenced by observing, that, if true, it was not original, as the same view had previously been taken by M. Audouard. He further stated that he had studiously examined the state of the spleen in 250 cases of ague, but that he found no grounds for supporting the theory of M. Piorry, but on the contrary, that he had seen numerous cases in which the fever had preceded the splenic engorgement, as well as many others in which the engorgement had remained long after the periodic attacks had subsided. M. Bouillaud considers rationally, that the engorgement is the result of the paroxysms, and not the cause.

January 19th.

After the reading of some uninteresting communications on the subject of æther inhalation, the discussion on intermittent fever was resumed by M. Castel.

January 26th.

This sitting was occupied with details of individual experience with the vapour of æther, none of which however are of sufficient interest to be repeated.

February 2nd.

ÆTHER-INHALATION.

The President announced that a commission of enquiry had been set on foot to make definite investigations respecting the effects of the æthereal inhalation.

M. Honoré related a case of neuralgia cured by it.

M. Jobert mentioned several successful cases, and alluded also to one in which insensibility remained for several hours. He stated that he did not consider it suited to long operations, but that it is perfectly applicable to those which can be performed with rapidity.

M. Blandin considers that patients under æther did in reality feel, but forgot their sensations.

M. Bouvier narrated a case of puerperal mania, in which he had exhibited the æther vapour; it had no beneficial effect, but did not appear to be prejudicial. In a case of painters' colic it was completely successful in relieving the pain.

OPERATIONS PERFORMED UNDER THE INFLUENCE OF ÆTHER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Not having observed in the Society's Journal any report of cases illustrative of the beneficial effect of the inhalation of the vapour of æther during surgical operations from this neighbourhood, I send you the two following cases, which are only valuable as confirming those already stated by other surgeons.

I am, Sir,

Yours obediently,

WILLIAM JOSEPH LUNN, M.D.,

Surgeon.

Hull, March 13, 1847.

CASE I.

Eliza Spinks, aged 32, a strong country woman, from whom I removed a large adipose tumour from the dorsum of the scapula. With the kind assistance of my friends my patient was brought under the intoxicating influence of the æther in three minutes. The entire operation lasted ten minutes, during which the only feeling at all assimilating pain was a sensation of cold drops of water falling on the shoulder, which caused her to shrink; this was probably at the time of the first incision, which was six inches in length. On being asked when laid down if the operation was over, she replied "she did not know," and has many times since declared that she suffered no pain, and was dreaming a pleasant dream. Little or no fever followed, nor was there any headache, which might have been expected, as she is subject to it. In ten days my patient returned into the country, and is now nearly well.

CASE II.

John Snee, a healthy boy, aged 18, with an increasing exostosis of the metacarpal bone of the little finger, the size of a hen's egg, caused by a crush in a coal pit three years ago. The pressure of the bony growth upon the metacarpal bone of the ring-finger, which had also been injured by the accident, has caused absorption of most of that bone, consequently a careful dissection was requisite to save the finger. The entire removal occupied twelve minutes; and the operation was completed, the arm in a sling in twenty. During the whole of this time the patient was perfectly insensible, except on making the first incision, which was probably owing to my commencing a few seconds too soon, before the complete effect of the æther was produced, but this felt merely like a scratch. The preparatory inhalation occupied eight minutes. During the whole time the boy dreamed that he was in Heaven, and did not return to consciousness until about a minute or so after the operation was finished, which he did without any unpleasant effect, although he breathed the æther more or less for full half an hour.

In the above cases the inhalation produced little or none of the ghastly distressing countenance or sense of suffocation as stated often to occur; this I attribute to the patient's breathing through the apparatus merely atmospheric air for the first minute or so until accustomed to the process, and then gradually admitting the vapour.

The narcotic effect was kept up in the first case by merely twice repeating the inhalation for three or four inspirations; and in the latter by keeping the mouth-piece constantly applied, and letting in more or less atmospheric air as was thought requisite. The pulse in these patients varied in a singular manner: in the woman it scarcely exceeded 80, and in the boy it rose at one time to 160, but dropped to 100 at the close of the operation. In neither did the æther produce the slightest injurious effect, or in any degree retard the healing process. It may be well to mention, that in the female there did appear for a short time so much exhaustion as to induce us to give a little brandy and water, but in the boy no such stimulant was necessary. In neither was there any depressing hæmorrhage.

In this town, as far as I have heard, the æther has not been much used, except in tooth-drawing, but in the few cases where it has, I believe no injurious consequences have occurred.

ABSTRACTION OF BLOOD IN THE NARCOTISM FROM ÆTHER-INHALATION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I beg to suggest in the event of a case of narcotism from the inhalation of æther, where the system seems unable to rally from its effects, whether the early abstraction of a few ounces of blood is not more likely to produce re-action than the administering of stimulants at a later period. Mr. Nunn's case in the Journal of the 10th instant, discloses the fatal effects of æther in a person comparatively of a sound constitution; its continued use for some minutes to mitigate the sufferings of the patient in a severe operation, was followed by symptoms of compression of the brain, verified by the *post-mortem* appearances in the stage of collapse. Brandy and ammonia were given, and failed, to arrest the fatal progress. It appears to me probable, where stupor continues an unreasonable time, accompanied with stertorous breathing, and it is to be supposed a state of the pulse and pupil of the eye, significant of congestion of the brain, depletion in accordance with the urgency of the symptoms is more likely to be effective; and the case justifies this question,—whether there is not greater danger to be apprehended in all cases in which æther for any time has been given, attended with little or no loss of blood to the system? I have not tried the æther in any case as yet, and feel myself open to a rebuke in offering observations unsupported by facts to your readers, but as the suggestion is a comparison of the effects of this poison with other stimulants, there appears no reason why the hint should not be given to arrest in others if possible the fatal consequences from so useful and powerful an agent.

I am, Sir,

Your obedient Servant,

J. E. BECKINGSALE.

Newport, Isle of Wight, March 16th.

ÆTHER-INHALATION.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Since the introduction of ætherization into this country, I have employed it in eight cases reqniring surgical operation, five of which were followed with the most satisfactory result. In the other three, some difficulty was experienced in the process of inhalation, in a great degree owing to the timidity of the patients, and only a partial effect accrued. The time required to produce the narcotic influence, varied from three to eight minutes. Females apparently were more rapidly and completely narcotized than males, and continued in a state of insensibility a longer period of time. Return to consciousness in all three of the females subjected to its influence was attended with hysteria, simulating the effects of stimulus, which lasted, however, but a few minutes. Five of the above cases were Infirmary patients, the remaining three private. In none did any alarming symptoms follow, notwithstanding the experience of some practitioners has been adduced to the contrary. I feel it a duty to record my testimony in support of the safety of æther inhalation, and regard it as a means emminently calculated to alleviate human suffering, in cases requiring surgical operations.

The apparatus found most easy of application, and producing the speediest effect, was simply a large bladder, furnished with an ivory tube for the mouth, and cushion for covering the lips; it was much to be preferred to one previously used of a more costly nature, and far more complicated in its construction, which consisted of a glass chamber and a flexible tnbe.

I remain, Sir, your obedient servant,

W. C. WORTHINGTON, F.R.C.S.,

Senior Surgeon to the Lowestoft Infirmary.

Lowestoft, March 1, 1847.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

MEMBRANA DECIDUA.

The account which Dr. Sharpey gave of the formation and structure of the membrana decidua in the uterus of the bitch, and which he inferred might apply to this membrane in the case of the human female, as also of all viviparous animals, has been amply confirmed by Bischoff. Having had the opportunity of examining the uterus of a woman supposed to have been impregnated about three weeks before death, he was enabled to demonstrate quite satisfactorily, that, as Dr. Sharpey had suggested, the membrana decidua in the human female, as in the bitch, is merely the ordinary mucous membrane of the uterus, considerably developed, and that it consists essentially of enlarged uterine follicles and their blood-vessels, together with an unusually large quantity of secretion which these follicles have poured out. The internal surface of the uterus presented an appearance quite different to its ordinary one, being finely villous; and this was especially evident on placing it in water, or examining

perpendicular sections of it. The surface itself, when looked upon from above, appeared as if perforated by a number of small apertures, or covered with numerous white points, and these, when examined by the microscope, were found to be the openings of cylindrical glandules. These glandules, or follicles, were from one and a half to two Paris lines in length, were held together by a transparent material, and terminated each by a blind extremity, which rested on the fibrous tissue of the uterus. They ran a somewhat wavy course, but never branched or anastomosed. Previous to impregnation it seems to be exceedingly difficult to discover these glands in the mucous membrane of the uterus. Probably they then exist in a very undeveloped state, but immediately on the occurrence of conception increase rapidly, and exude an abundant secretion. Of these glands and their secretion (together with blood-vessels,) the membrana decidua and later on the placenta essentially consist. The statement that a membrana decidua exists in the Fallopian tube, as well as in the uterus, in cases of Fallopian impregnation, Bischoff combats, by observing that so far as has yet been seen, the lining membrane of the Fallopian tube contains no glands by which the formation of a structure corresponding to an ordinary membrana decidua could be effected. A similar view to the above, in regard to the nature of the membrana decidua, has been advocated also by M. Courtz, who considers this structure to be merely a somewhat altered condition of the mucous membrane of the uterus.

A description of the mucous or lining membrane of the uterus, in the unimpregnated state, has been furnished by M. Deschamps. He states that this membrane, when carefully dissected off, appears as a whitish, very delicate, and friable structure; it is continuous above with the membrane lining the Fallopian tubes, and below, at the neck of the uterus, it is united with the mucous membrane of the vagina. He mentions also, that with a lens he has distinctly observed the free surface of the membrane to be finely villous, owing to the number of minute follicular glands with which it is beset; from the orifices of these he observed a viscid fluid to exude on pressure. This fluid, with which the interior of the uterus is moistened, possesses all the ordinary characters of mucus.—*Dr. Kirke's Report on Anatomy, &c.*, in *Dr. Ranking' Half Yearly Abstract*, Vol. IV.

PATHOLOGICAL CHEMISTRY.

CONDITION OF THE BLOOD AFTER DEATH FROM STRANGULATION.

M. Cicerone having observed that after death from asphyxia the quantity of fibrin in the blood is diminished, and that after the respiratory movements have ceased circulation of the blood still continues for some time, was led to infer, that in those cases in which respiration is stopped by the application of a cord round the neck, and in which also the return of blood from the jugular veins to the heart is at the same time prevented, the circulation of blood through all other parts of the body below the cord being in the meanwhile continued, and the conversion of arterial into venous blood continuing (though imperfectly,) to take place, the blood accumulated in the jugular veins would be in its natural condition, whilst that in all other veins below the constricted part of the neck would have suffered a diminution in the quantity of its fibrin. If such was the case, it would be an important fact in relation to medical jurisprudence, inasmuch as this difference between the character of the blood examined from the jugular veins and that from the rest of the body, would not be observed in those cases in which a cord had been tied around the neck of a person already dead. M. Cappa has recently undertaken some researches on the subject. In ten hens which he strangled, death was caused six times by asphyxia and apoplexy conjointly, and twice by asphyxia alone, and twice by apoplexy alone. In the two last cases the corpuscles of the blood in the veins above the constricted part of the neck, were found beneath the microscope to be distended, most of them deprived of their nuclei, others elongated, and others more or less broken up; whilst the corpuscles of the blood from other parts of the body had their natural appearance. But, in the two cases in which death resulted from asphyxia alone, the above-mentioned alterations in the corpuscles occurred in the blood of parts below the seat of constriction; and in the six cases in which death was produced by asphyxia and apoplexy conjointly, the same alteration of the corpuscles was observed alike in all parts of the body. The test proposed by M. Cicerone would therefore, according to M. Cappa's account, only be available in the cases where death was caused by apoplexy, and not in those cases in which death from strangulation is produced by apoplexy and asphyxia conjointly, and which are most frequent. M. Cappa, moreover, has found that the blood in the jugular veins above the ligature is thicker, and contains a larger proportion of fibrin, (as M. Cicerone inferred,) in death from apoplexy alone; whilst in death caused by asphyxia alone, an opposite condition was observed. This test, as well as the other, will therefore fail to be of service in those cases (the large majority,) where death is due to the combined influences of asphyxia and apoplexy.—*Medical Gazette*, Dec. 11, 1846., from *Heller's Archiv.* Heft, 2, 1846.

NATURE OF DIABETES.

M. Bouchardat has published another memoir on this obscure disease, of which the following is a summary:—

1. Diabetes consists essentially in a perversion of the digestion of feculent substances. These articles of food instead of being dissolved in the intestines by means of the pancreatic juice, as in health, are dissolved in the stomach, giving rise to the formation of diastase.

2. The theory of the neutrality or alkalinity of the blood in this disease is erroneous, and the continuance of food containing fecula together with the administration of soda is hazardous.

3. It is impossible, for various reasons, to accomplish more than temporary amendment in hospitals, but if we meet with a patient whom we can treat at home, surrounded with all the necessaries of life both hygienic

and dietetic, we may in many cases accomplish a complete cure, provided there is neither tubercle in the lungs or any disease of the pancreas and its ducts, and that the patient has resolution to avoid the use of food containing fecula.—*Gazette Médicale*, Janvier, 1847.

PATHOLOGY.

ON THE CUTANEOUS ERUPTIONS INDUCED BY VARIOUS MEDICINAL SUBSTANCES.

Opium.—The eruptions which in certain individuals follow the use of the preparations of opium are always of an exanthematous nature. In general they consist of red isolated patches not unlike those of measles. This kind of eruption is rare.

The *Solaneæ.*—The eruption induced by the ingestion of the preparations of this tribe of plants are also of the order exanthemata, and are as uncommon as those which are the effect of opium. The patches are larger and irregular, resembling scarlatina.

The *Oleo-resins.*—All the medicinal substances of this class are liable to be followed by cutaneous eruptions, but none so frequently as turpentine and copaiba. The eruption very much resembles that produced by opium and belladonna, being sometimes measly, at other times scarlatinous in its appearance. It is a rare exception to see either vesicles, pustules, or papules.

Cod-liver oil.—This medicine sometimes gives rise to a form of eczema, which appears generally about the fifth day from the commencement of its use; it is, however, rarely observed.

Iodide of potassium.—The eruptions which follow the use of this medicine are far from uniform, sometimes being eczematous, at others pustular, as in acne. It sometimes happens that the skin escapes the action of the medicine, and that the mucous membranes are attacked instead; in such cases we observe coryza and conjunctivitis, which cease as soon as its use is suspended, but which will not yield to topical treatment as long as the medicine is persisted in.

The discrimination of the cutaneous affections which are induced by different medicinal substances taken internally, is of no slight practical importance; we have seen ignorance of these characters and causes give rise to very unpleasant mistakes.—*Annuaire de Therapeutique*, 1847.

STRONGULUS GIGAS IN THE HUMAN KIDNEY.

A recent number of the Journal of the Academy of Medicine of the Loire Inférieure records the curious case of the presence of a living strongulus in the human kidney. The subject of the case was a farmer, aged 60, of intemperate habits, but robust. After a debauch of several nights' duration, he was seized with severe pains in the region of the right kidney, which were attributed to renal calculus. The resources of legitimate medicine, as well as of numerous quacks, were exerted in vain for the relief of his sufferings, a transient cessation from his pain being only obtained from the use of sulphuric æther and the spirits of turpentine. At the expiration of three years' continued suffering the patient had become reduced to a skeleton. For the last ten months of his life, indistinct undulatory movements were visible over the affected kidney, which were accompanied by a sensation of "creeping" internally. The patient at length died in a state of complete marasmus, when dissection revealed the presence of a large *Strongulus gigas* in the right kidney, the structure of which had become greatly disorganized.

ON THE MEANS OF ASCERTAINING WHETHER THE SOURCE OF A UTERINE LEUCORRHŒA BE IN THE FUNDUS OR CERVIX UTERI.

Dr. Mitchell considers that the above point may be determined by means of an instrument which he has devised. This consists of a gum-elastic catheter, with a stilette, to the bulbous extremity of which a portion of litmus paper is fixed. The catheter is introduced into the cervix uteri, and the stilette being pushed forwards, the litmus paper is allowed to remain in contact with the secretion. It is then withdrawn into the catheter before the latter is removed. The entire instrument is then withdrawn, and the paper examined; if it remains of its original colour, Dr. Mitchell considers that the disease is located in the cervix; if, however, it be reddened, we have evidence that the fundus is the source of the discharge. — *Dublin Medical Press.*

[There appears to us to be one source of fallacy in this experiment, which Dr. Mitchell does not take into account, viz., the acid nature of the vaginal mucus, the accidental contact of which would equally redden the litmus.]

MATERIA MEDICA.

FORMULÆ FOR THE IODIDE OF IRON.

The Messrs. T. and H. Smith now make a solution of iodide of iron in a Florence flask, with six drachms of pure iron filings, two ounces two drachms of iodine, and four ounces and a half of cold distilled water. This mixture is boiled till the liquid loses its colour; it is then filtered rapidly into a clean flask, and evaporated at a boiling heat. They obtain the compound either as a crystallized hydrate, or in an amorphous anhydrous form, according to the extent of the evaporation, and inclose it, without the slightest delay, in small well-corked bottles. As all the solid preparations are liable to change, they farther recommend powdering their anhydrous iodide as soon as it is taken from the flask, and then instantly to incorporate it with twice its weight of pure refined sugar in powder, and to make it up in mass with honey.

M. Calloud, in a memoir on this salt, points out the advantages of preparing it by double decomposition. He shows, by analysis of various specimens, that when the salt is prepared in the direct manner, and its solution evaporated to dryness, there almost always occur flakes of crystallized iodine adhering to a bluish mass, friable and insoluble in water, which is no other than a mixture of reduced iodine and sesqui-iodide of iron. The following are his observations on the iodide of iron obtained by double decomposition:—

By reducing iodide of potassium and sulphate of protoxide of iron to a fine powder, and triturating the

mixture of the two salts, we obtain the protiodide of iron.

1 part of sulphate of crystallized protoxide of iron - - - - - - - - - 161.52
1 part iodide of potassium - - - 206.94

The double decomposition being produced by the assistance of the water of crystallization of the sulphate of iron, we treat it with alcohol of 85° per cent. which only dissolves the iodide of iron that is formed. The alcoholic solution has all the characters of the protosalts of iron; and the re-action of the two salts is complete. The sulphate of potass is, in this case, in the condition of the insoluble salts.

The iodide of iron, thus mixed with the sulphate of potass, may be employed therapeutically with undoubted advantage in a dry state.

The following formula may serve for certain pharmaceutical preparations, having iodide of iron for a base :—

Crystallized sulphate of iron - - - 3 parts.
Iodide of potassium - - - - - 4

It is important to choose the sulphate of iron in small, colourless, and translucent crystals, which integrally represent the protoxide, with seven proportions of water. The iodide of potassium ought to be perfectly neutral and pure; the least excess of alkali in the iodide would also be at once shown by the sulphate of iron, which, in this case, is a good test. To be satisfied of the purity of the substances, the mixture of the two salts being dissolved in a certain quantity of water, the latter ought not to be rendered cloudy by the green or yellow oxide of iron, which would indicate the employment of a basic iodide of potassium, or a sulphate of iron, partially peroxidized.—*Dr. Day's Report* in *Ranking's Half-Yearly Abstract*, Vol. IV.

Mr. Hemingway has more recently proposed the following formula :—

Take of Iodine, (pure and dry,) oz. iij., dr. vij., scr. ij.
Iron filings, (clean,) . . oz. ij.
Distilled water, ... *q. s.*

Add, little by little, the iodine to the iron filings, in a mortar, containing six ounces of water, allowing each action to cease previous to the next addition; agitate the mixture without additional heat until it assumes a green colour; transfer the liquid portion into a measure; wash the filings that remain with half-an-ounce more of water, again, and a third time; mix the washings with the decanted fluid, and make up exactly to twelve fluid-ounces and a half; call it "the solution," and keep it in a well-stoppered bottle, with iron wire and filings; each fluid-drachm will contain thirty grains of crystallized iodide of iron. When wanted for use pour off without disturbing the sediment and pass through coarse filtering paper.

From this solution it is proposed that the syrup should be made, and from it also (for the purpose of dispensing,) inferior solutions of any required strength may be easily obtained. Should it become brown by keeping, and it will if the stopper is insecure, the bottle must be shaken, that the green appearance may be recovered; and should this be the case when syrup is about to be made, time must be given for the dregs to subside, in order that filtration may proceed as rapidly as possible.

To make the syrup :—

Take of Simple Syrup, (*white*,) P. L. - - - 15 fluid-oz.
Solution of Iodide of Iron, as above, 2 fluid-oz.

Put the syrup into an upright pan—a common saucepan lined with enamel is suitable—and accurately balance the whole; next, apply heat, until by a gentle ebullition it has decreased in weight two ounces *avoirdupois*; remove it from the fire; get ready the "solution," and, without loss of time, mix it intimately with the reduced syrup, and bottle directly (if consumption is small,) in four-ounce bottles; when quite cold shake well up. Each fluid-drachm contains four grains of crystallized iodide, the equivalent of rather more than three grains of the dry.—*Dublin Medical Press*, Jan. 10th.

THE PROVINCIAL MEDICAL DIRECTORY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Having understood that one of the principal objects of the London and Provincial Medical Directory was to furnish the profession, not only with the names, but also with the *qualifications*, of its legitimate members, I may, perhaps, be allowed, through the medium of your Journal, to express my surprise that so many persons should be introduced as recognized practitioners, without the slightest intimation as to the nature or date of their credentials. The existence of this defect must have attracted the notice of all who have glanced over the pages of the Directory; and my only motive in thus mentioning the error, is the hope that hereafter it may be corrected. Were the omissions of the specific qualifications rare and accidental, it might be ungenerous to make any comment upon them; but that this is not the case, may very readily be *proved*. For example :—In the first twenty pages of the provincial department, there are upwards of a *hundred* names without *any* statement of the premises upon which the parties are entitled to a place in a medical list. In the next twenty pages, there are also upwards of a hundred omissions of the same kind; and in the next twenty pages likewise; so that in sixty pages there are *three hundred* claimants who give no account of the foundation upon which their claim rests. I have not made an actual enumeration beyond the sixtieth page, but conclude that the remainder of the work is chargeable with a similar defect.

Trusting that the editors will in future *exclude* those who will not take the trouble to supply an accurate and definite description of themselves,

I remain, Sir,
Most respectfully yours,
CANDIDUS.

March, 1847.

[We have received other communications pointing out the same defect.

ÆTHER-ADVERTISING.

It is with regret that we feel called upon to notice the subjoined letter on the subject of æther-inhalation. On referring to the "Provincial Directory," we observe the name of "Matthew Carter, Castle Cary, Somerset, Physician, M.D., Memb. Roy. Coll. Phys., Lond., 1846," &c., &c. It cannot be supposed that the writer of the letter, and the Member of the Royal College of Physicians, whose name appears in the "Directory," are one and the same individual, and the genuine Dr. Carter owes it alike to the College, to his professional brethren, and to himself, immediately to disavow the use which has been so reprehensibly made of his name:—

THE VALUE OF THE VAPOUR OF ÆTHER IN THE TREATMENT OF DISEASE.

To the Editor of the Sherborne Journal.

SIR,—I feel it my duty energetically to draw the attention of the public, but more particularly of my medical brethren in this county, to an important, though simple fact,—namely, to the value of the inhalation of æther in the treatment of some of those various chronic, and indeed acute forms of disease, which have hitherto unhappily baffled the best-devised means of our art.

The result of my experience of its efficacy in the treatment of disease, has astonished and delighted me. Taught hitherto to believe, and observation and experience having confirmed my teaching, that there existed not in the details of medicine any agent which should deserve the name of "specific," I cannot express the amount of my gratification in having thus to say, that the vapour of æther, judiciously applied, in my opinion, approaches nearer unto what may be understood by the term "specific," than any other therapeutic agent with which we are acquainted.

The most violent paroxysms of gout, of rheumatism, of neuralgic affections, tic-douloureux, &c., &c., have yielded, as it were magically, to the influence of this agent, and in no one instance in which I have applied it have I had any reason to doubt of its efficacy; on the contrary, the transition from acute pain to the most perfect ease, has, in each instance, attested its most salutary property; and it is right to mention, that in no one case have I found it necessary to carry the inhalation of the vapour so far as to induce any thing approaching to insensibility; the slightest influence of the æther produces *immediate results*, and pain begins to cease almost instananeously.

I trust I have said enough to draw the attention of my medical brethren to *the value of the fact*. I shall be happy if, by this means of publicity, I induce them to test, and attest for themselves, the truth of what I now assert, confident as I am that an agent is discovered of stupendous power, which in the hands of our profession, rightly wielded, will, I doubt not, prove one of the most valuable, as it is, I think, most decidedly one of the most certainly efficacious means of treatment to which the medical profession has access.

Your obedient servant,
MATTHEW CARTER, M.D.

Castle Cary, February 15, 1847.

P.S.—I hope shortly to lay before the medical profession a short pamphlet on this subject.

Medical Intelligence.

FATAL EFFECTS OF ÆTHER: INQUEST.

An inquest has been held on a young woman, the wife of a hair-dresser, at Spittlegate, in the county of Lincolnshire, from whom a tumour had been removed while under the influence of æther. She never rallied, and died without the slightest re-action having taken place, sixteen hours after the operation. The following verdict was returned:—"That the deceased, Ann Parkinson, died from the effects of the vapour of æther, inhaled by her for the purpose of alleviating pain during the removal of a tumour from her left thigh, and not from the effect of the operation, or from any other cause." The surgeon who performed the operation stated that he fully concurred in the verdict, as he had no doubt whatever that the æther alone was the cause of death, and it was a duty he owed to the public to say so.

GLOUCESTERSHIRE MEDICAL AND SURGICAL ASSOCIATION.

THE MEDICAL REGISTRATION BILL.

Some time since a meeting of this Association was convened for the especial purpose of considering what course should be pursued in reference to Mr. Wakley's new Registration Bill, when the following resolution was adopted:—"That the Medical Registration Bill proposed by Mr. Wakley is cordially approved by this Association, and that it be energetically and promptly supported."

The Bill, it is understood, is now in the hands of Counsel; but when the proper time arrives, active measures will be adopted to carry the resolution into effect.

MEDICAL APPOINTMENTS.

Dr. William Wegg has been appointed Physician to the Westminster General Dispensary, in the room of Dr. S. W. J. Merriman, resigned. Dr. Merriman has been appointed Consulting Physician to the Institution.

Dennis Phelan, Esq., Surgeon, of Dublin, has been re-appointed an Assistant Poor-Law Commissioner for Ireland.

M. Gibert has been elected a Member of the Académie de Médecine, Paris, in the Section of Therapeutics.

M. Civiale has been elected a Member of the Académie des Sciences, Paris, in the room of M. Bory de St. Vincent, deceased.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, March 12th:—G. Allbutt; C. M. Empson; H. Barnett; H. Green; W. Faithfull; J. M. Birom; J. Rice; C. S. Hugo.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, March 4th:—Peter Brady; Thomas Orton, Rothwell; William Cumming; Edmund John Burman, Banstead; James Graham, Liverpool.

OBITUARY.

Died February 20th, at Cahir, of fever, Michael Daniel, Esq., Surgeon to the Fever Hospital and Dispensary.

February 28th, of fever, David Smith, M.D., Medical Attendant of the Middleton Fever Hospital and Dispensary.

Lately, at the Grange, Melton, aged 70, Thomas Bland, M.D., a Magistrate of the County of Suffolk.

Lately, aged 43, Edward Lubbock, M.D., Physician to the Norfolk and Norwich Hospital.

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(Fourth Series of Experimental Researches.)

By William Addison, M.D., F.R.S., Malvern.

(*Continued from page* 120.)

IX. Scrofula.

Scrofula is the term used to designate a particular state or condition of the living body, rendered apparent by the phenomena of its nutrition and diseases. The term, whatever may have been its origin, seems like many others in medical science, to have been handed down with reference to the human structure for convenience sake, rather than for any other reason. Writers upon the subject of scrofula, for the most part, reiterate one after another certain external appearances in the general contour of the person—in the eyes, lips, nose, countenance, or complexion, by which they say those individuals who are scrofulous may be distinguished from others who are not so. But we shall hereafter shew that no satisfactory practical distinctions can be safely made upon such grounds, the constitutional disposition not declaring itself until the qualities of the textures, and their capacity of withstanding injurious influences, have been tested and declared by some irritating or disturbing cause, giving rise to an unusual local increase of nutritive matter; when the form of the morphology or metamorphosis—the conformable or unconformable type of the changes—pronounces the constitutional diathesis.

If there be one fact better established than others in respect of scrofula and scrofulous diseases, it is their hereditary character, the offspring exhibiting bodily and mental powers, and forms of disease similar and analogous to those which have been known to exist previously in one or both parents. This transmission of structural or constitutional and other qualities, from parent to child, is one of those remarkable facts in living bodies, which we look to the recent rapid advances of physiological science to elucidate. To say that children inherit the dispositions and diseases of their parents, and to rest content with the barren assertion, is to leave to conjecture questions of the highest interest to medical and moral science. If the lineaments of the face, the colour of the eyes and hair, the tones of the voice, an ear for music, and mental aptitude, be handed down from father to son, they must be so by a wonderful consentaneous harmony of organization—an almost incredible conformability in the morphology of nutrition; and if the physiology,—if the constitution, temperament and mind, be so similar, then, however little we may be able to explain the fact, it follows almost necessarily that the pathology and diseases will prove so too;—not scrofulous diseases exclusively, but all others also.

"The most certain evidence of the existence of a scrofulous disease," observes a recent medical writer, "is afforded by the production of a soft brittle unorganized matter, resembling curd or new cheese, which is found mixed with the contents of abscesses, or deposited in rounded masses of different degrees of firmness, and varying in bulk from the size of a millet seed to that of a hen's egg; sometimes it is enclosed in cysts, and occasionally it is diffused, as if by infiltration, through the natural texture of the part. To the rounded masses of this substance the name of tubercle has been assigned, and the substance itself has been named tuberculous matter."

X. Seat and Nature of Tubercles in the Lungs.

Tubercular consumption and phthisis are terms used to designate that species of disease which consists in the filling up of the air-cells of the lungs,* and the destruction of their vascular walls by a soft, brittle, white matter, named tubercle or tuberculous matter. The best and most recent pathologists have differed in their statements and opinions regarding the seat and nature of tubercles in the lungs, nor are they agreed as to the changes they undergo. Laennec describes them as small firm bodies, which gradually enlarge, then soften, and by degrees become converted into a liquid mass. Andral differs somewhat from Laennec, he says that tubercles soften, not from any spontaneous changes in themselves, but from an admixture of purulent matter poured out from the living texture immediately surrounding them. Dr. Carswell states that

* Dr Cumin in *Cyclopædia of Practical Medicine*, Vol. 3, p. 701, Art. Scrofula.

tubercles originate from morbid changes in the blood, and that their most frequent seat is the surface of the mucous membranes; this author believing, in common with many others, that the membrane of the air-cells of the lungs is a mucous membrane. Dr. C. J. B. Williams states that "lymph, pus, and tubercle, pass by imperceptible gradations into each other;" and in this opinion I concur, in so far as that pus may pass into tubercle or mucus, or into a mixture of tuberculous and mucous matter, but the converse never can occur.

Tubercles exist in the lungs more frequently than is generally imagined. Of the numerous apparently-healthy lungs which I have examined in the course of my researches, I have found them in about one-third. In their early state they escape notice, unless searched for with a lens in very thin sections, gently extended upon a dark back-ground. In order to make out correctly the primary situation of a tubercle, the examination should be made in the lungs of young persons who have died of other diseases; for in those who die of consumption, so many changes have taken place, and the several textures of the lungs have been so altered, that it is impossible to find tubercles in that early condition in which alone their situation, in or upon the membrane of the air-cells, can be determined.

I have repeatedly examined with the microscope the material deposited in the air-cells of the lungs in *pneumonia*, and compared its characters and appearance with that forming a tubercle, without being able to detect any more essential or constant difference between them, than exists between recently excreted and old pus. The same class of objects,—incoherent colourless cells, molecules, and granular matter, appears to constitute the material in both cases,—in hepatization or consolidation of the lung from inflammation, and in consolidation from tuberculous matter; and in both cases also the material takes primarily the shape of the air-cells in which it is seated. In the material forming the consolidation resulting from inflammation, incoherent cellular forms predominate, as they do in recent pus; whereas in tuberculous matter, granular masses and molecules greatly predominate, as is also the case in old pus. And were we to imagine the fluid element of old pus removed or absorbed, the remaining solid matter would be, in my opinion, tuberculous matter; the colourless elements of blood, pus, and tubercle passing by imperceptible gradations into each other.*

In pneumonia the consolidating material is as it were suddenly thrown out over a wide extent of lung. All the blood-vessels are loaded with colourless elements. The blood itself when withdrawn assumes a buffy coat, and the texture, from the various blendings of the red colour of the blood with the white colour of the new material separated from it, assumes various hues between dark red and whitish yellow.

In phthisis, on the other hand, the consolidating material is deposited at distant points, in a much slower manner; it becomes as it were old before it becomes visible, and I have seen sections of the lung display an appearance precisely analogous, and indeed very similar to that of the face in small pox, and this in a patient who did not die of consumption.

My researches have been in like manner extended to the characters and appearances presented under the microscope by the material taken from pimples, boils, and all kinds of eruptions on the skin, and in all these instances incoherent colourless cells, granular matter, and molecules, have been found in the greatest abundance. Moreover—and it is a fact of much importance—the same objects have been profusely detected, not only in the fixed textures surrounding the morbid matter, but likewise in blood taken from the vessels administering to their nutrition. And it would appear that when any texture becomes involved in a hurtful or destructive inflammation, or in a tuberculous or scrofulous disease, that its physiological type is altered and its function impaired; the structural elements, whatever may be their normal qualities or characters, become more and more uniform, and at length corpuscular, the corpuscles being apparently identical with those circulating in the blood.

It has been said that tubercles arise from "an error of nutrition," which is perfectly true, but no practical advantage is derived from the use of a few words which are applicable alike to all diseases.

XI. Structural Changes produced by Scrofulous Disease.

A woman, aged 34 years, died of scrofulous disease of the bones and consumption. The body was examined a few hours after death. Four sinuous canals with external thickened outlets, discharging mucus, lymph, and clotted pus, existed on the right shoulder, leading down to diseased bone and other textures at the joint. Another sinus passed through the breast bone into the fibrous or areolar texture beneath it, entering the anterior *mediastinum*. The internal surfaces of all these sinuses were excreting incoherent cellular forms, and when closely examined with a lens, were found red and vascular, covered with muco-purulent matter, mixed with clots and white flakes. The clots and white flakes examined with the microscope were found to be incoherent, cellular, or corpuscular textures.

On opening the chest, the sinus passing through the breast bone was found traversing, by various channels, the areolar texture of the anterior mediastinum, which was extensively changed in character and appearance; it was much thickened, much more red and vascular,

* By the term *old pus*, the reader will understand that I mean *matter* which has been a long time excreted, and in which the corpuscles or cells having broken down, there remains a thick, more or less fluid material, composed of granular forms and molecules.

and the new anormal vessels and textures had evidently been the source whence the muco-purulent matter, the flakes, and clots had been discharged, and to which the external opening of the sinus had given vent. The new and thickened textures, and the coats of the new vessels were examined with a high magnifying power, (750,) and they were generally found softer and more brittle than the normal fibrous texture, and multitudes of incoherent cells were found upon them, and distributed among the remaining fibres of the structure.

The lungs externally were of a deep purplish slate colour, their volume was less than natural, and they adhered firmly to the walls of the chest. On pressing them between the fingers and thumb, numerous hard bodies were felt in their interior, and on making sections, tubercles and cavities containing pus were found disseminated through them. The tubercles were in some places hard, in others soft, and in others they appeared to have degenerated into a completely fluid pus. The cavities in many places had several sinuous communications with each other, the sinuses or channels running through a hardened and consolidated texture totally different from anything resembling the healthy parenchyma of the lung, and here and there air-tubes opened into the interior of the cavities. The textures forming the walls of the cavities bore no resemblance to the normal textures, and when the muco-purulent matter was removed from their free surface, they were seen with a lens to be traversed by numerous long varicose and tortuous red vessels, totally different in distribution and arrangement from any of the vessels of the normal textures. Similar strange vessels were also seen running along the borders of the texture, contiguous to, and bounding the outline of, the tubercles. The coats of many of the smaller vessels, and the textures upon which they were distributed, were examined with the microscope, and found composed for the most part of incoherent colourless cells, mingled with granular matter and molecules.

Fig. III.—A capilliary vessel in the fibrous or areolar texture, (normal.)

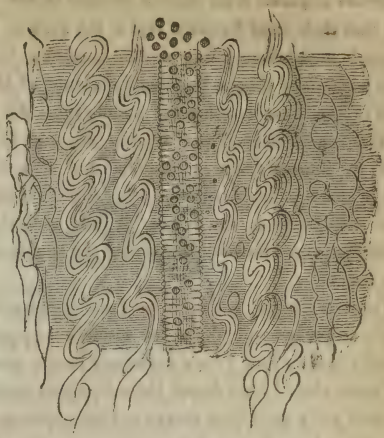

Fig. IV.—A larger vessel in the areolar texture, (normal.)

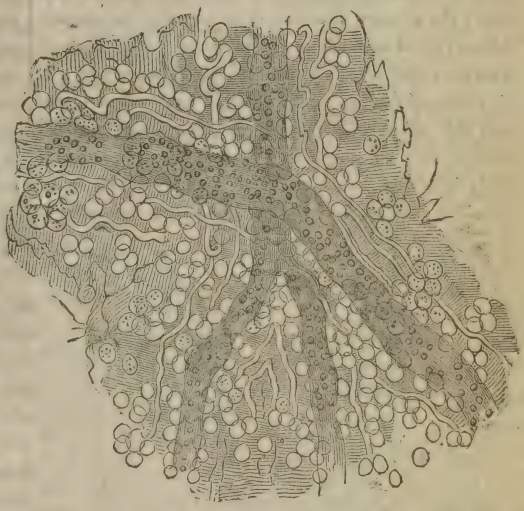

Fig. V.—Vessels excreting pus and mucus, from a scrofulous sinus in the arcolar texture of *anterior mediastinum*. Case 1.

The textures were not tough, coherent, and elastic, but soft, and very brittle ; and it was only here and there that the waved and tortuous filaments, copiously found in all the minute vessels traversing the areolar texture of the healthy lung, could be discovered.

(*To be continued.*)

ON VARICOSE VEINS AND THE ULCERS DEPENDENT ON THAT STATE

By John M. Banner, Esq.
Senior Surgeon to the Northern Hospital, Liverpool.

There are few diseases more painful or distressing in every point of view than ulcers dependent on a varicose state of the veins, and there are few diseases which have occupied the attention of the profession more than this. Much has been written, and many are the modes of treatment recommended. During the period that I was a pupil and house-surgeon at St. George's

Hospital, which extended over the year 1818 and to the end of 1823, more than an ordinary degree of interest existed on the part of the surgeons of that Institution in the treatment of this disease. During that time the ligature was applied to the vena saphena, a portion of the vein was cut away, and a division of the vein was also effected by cutting. Such indeed was the interest excited that we severally partook of it. The same interest has continued with me up to the present day; and from the writings and lectures of Sir B. Brodie, we may conclude that it has continued with him also. The energy and persevering industry of Sir B. Brodie has ever been so great that we cannot feel surprised that he has continued, with unabated ardour, his endeavours to master this troublesome disease, as he has done in innumerable other instances. My interest in this ailment has led me to watch the various means recommended for its cure or alleviation. I have in many instances tested their value. It is the results that I wish to bring before the profession, and though in several of the modes of treatment, from their very marked unsuccessful issue, I have been held back from trying them so fully as I could have wished, where the plan has succeeded in my hands, I have given it a full and fair trial; where it has not done so, or where it has failed in the hands of others, I have contented myself with giving extracts from the writings of those who advocate it. I am unprepared to offer anything new on the pathology of the disease; nevertheless, I have thought it well, before entering on the treatment, to draw attention to certain selections which I have made from distinguished writers, on the pathology and other matters connected with it; this I do without apology, as I consider they will prove of advantage in the contemplation of the subject.

The late Sir Astley Cooper, in speaking of this condition of the veins, remarks that it may arise from a variety of causes; the more immediate one is either a thickening of the valves, so that they are incapable of approximating, or a rupture of the valves. In either case the effects will be the same; the blood pressing in one uninterrupted column, the veins become distended and serpentine, and the valves widely separated from each other; their arteries by their powerful attempts to return the blood to the heart soon excite inflammation. This opinion appears to have been adopted by several other surgeons.

Signor Rima, the Surgeon-in-Chief of the Hospital at Venice, in his "Treatise on the Proximate Cause of Varicose Tumours in the Lower Extremities," states that the real proximate cause is a reflux-motion of the blood in the veins,—for instance, the blood from the femoral vein retreats into the saphena, and is driven backwards from the groin towards the foot, by a power peculiar to these veins. He comes to this conclusion from the following facts:—

1st. When a surgeon removes a portion from a varicose vein in a living person, the blood is seen to spout from the upper end, as it does from an artery.

2nd. In those persons in whom varices have been caused by wearing tight garters under the knee, the veins are remarked to be more distended above the band than below it.

3rd. When the operation for varix is performed, either by the ligature or excision, those varices which are situated below the ligature or excision, are seen to contract and finally disappear, whilst those situated above remain stationary or increase, which would not be the case if the blood in these vessels flowed, as it usually does, from below upwards, as the weight of the column of blood from above acts in such a manner as to paralyze the valves of the veins, and thus keep up the communication between the individual varices.

4th. The pathological anatomy of varicose veins exhibits, in the lower extremities, hypertrophy of the walls, and a structure like that of the arteries. He thinks that inflammation following on a passive dilatation of the weak venous parietes between every two valves, with the weight of the column of blood from above, may be the cause of this hypertrophy; from this, chronic inflammation and thickening follows, and a change of structure.

Andral specifies several varieties of the disease:—

1st. Simple dilatation of the veins, without any other alteration, and either extending all along the vessels, or confined to particular points of them.

2nd. Dilatation of the veins, attended with a thinner state of their coats, and it may be either an uniform, or an irregular dilatation.

3rd. Uniform dilatation, with thickening of the coats of the veins.

4th. Dilatation, with thickening of the coats and interspaces between the varicose enlargements. In the two latter cases, as the vessel increases in diameter, it also becomes elongated and tortuous. This is the ordinary form of varices.

5th. Septa or partitions are formed in the vein, whereby its cavity is divided into small cells, in which the blood accumulates and coagulates.

6th. In the last form of varix, described by Andral, "from careful dissections, there are, in addition to the disposition exhibited in the fifth variety, various irregular perforations in the sides of the vein, and the vessel thus communicates with the surrounding cellular membrane, which is generally more or less diseased, as is exemplified in hæmorrhoids."

Mr. Syme, of Edinburgh, enumerates tall stature and largeness of the veins, as predisposing to this disease; constipation, pregnancy, and sedentary occupation, favour its actual commencement. Sir Everard Home observed, that in the army the grenadier companies are especially subject to varicose veins. Sir B. Brodie remarks that cooks are very liable to this diseased state of the veins, and enumerates

certain exertions as liable to produce it, and remarks that he has known a few instances where the varicose state of the veins appeared immediately after hard walking. Professor Cooper enumerates tall stature, large size, a long perpendicular course of the veins, as predisposing causes to the disease.

It appears to me that there must exist a predisposition to this disease in the person affected,—some peculiarity in the structure of the veins,—my experience does not bear out the observations of several writers, that persons of tall stature and large frame are the most liable to this disease. I have remarked that those of short stature and spare habit are also much affected with it. When Sir Everard Home stated that the grenadier companies are very liable to varices, he should have added also, that soldiers are subject to hard walking, which is given as a cause of this disease by Sir B. Brodie, and that they, in the days of Sir E. Home, wore the garter and knee-breeches, which, according to Signor Rima and Sir B. Brodie excite the varices. In the many cases which have come under my care, I have found that those who have undergone severe exercise of the lower limbs, whether they be tall or whether they be short, have been the subjects of this disease, and have had occasion to remark that many of the footmen in London are subject to it, those more particularly who were required to show a good leg and had to stand many hours together poised on the toes behind carriages. These men garter tightly, and where the predisposition existed, the practice no doubt acted as an exciting cause. Those subject to an exposure to great heat (as for instance cooks and foundry men,) I have observed are very liable to it. What is it then that causes this predisposition? According to Sir B. Brodie, the disease has been produced immediately after hard walking, proving at once that the coats of the veins were weak and easily dilated, or that the valves were defective; and the fact that many of the persons afflicted, have one vena saphena only diseased, proves that tallness of stature, largeness, and heat, do not entirely produce the disease. And again, many hundreds under exactly the same influences, escape the disease, which to my mind would at once prove a predisposition to it in certain individuals, which from an excitant developes itself. Women having children are subject to an enlargement of the saphena and its branches; in the several cases which I have met with, the varices disappeared at the seventh month of parturition, proving that the diseased state before alluded to did not exist. I recollect one case in particular in which a lady was seized suddenly at the fourth month of pregnancy with great pain and stiffness in the legs. On examining them I found the superficial veins generally distended, and the limbs presented a bluish appearance; the feet were cold. In this case the veins were not tortuous nor knotty; they felt generally distended. This state continued until the seventh month, when the limbs resumed their natural appearance, and continued perfectly well until the lady was again four months advanced with child, the varices then re-appeared, and disappeared as usual at the seventh month. This effect has been produced on four successive occasions, and in every instance the result has been the same. I have met with three similar instances. I fancy that when Andral enumerates a simple dilatation of the veins as a variety of this disease, he must allude to such an instance as those I have referred to, and which can scarcely be considered a true state of varix.

That there is some peculiar predisposition to this disease is manifest from the fact that it very frequently happens that the saphena vein in one limb is alone affected, which would scarcely be the case if it depended only on the causes enumerated. A patient came under my care in whom there was a large cluster of varicose veins on the inside of one knee, forming a tumour as large as an egg, which she stated came suddenly during parturition, and has continued slightly increasing for eight years. This is the only part affected.

The veins most liable to become varicose are the spermatic, hæmorrhoidal, and saphena. These veins, from the peculiarity of their situations, are liable to be acted on by pressure, therefore we may conclude that pressure has much to do in rendering them distended, knotty, and tortuous. I am not prepared to state what the exact condition of the vein may be prior to the varicose state; there can be no doubt that a diseased action exists, most probably in the valves. We seldom have our attention drawn to the stage of the complaint alluded to; when applied to we usually find the vein tortuous and enlarged, accompanied with an ulcer in the leg, and where we have an opportunity of examining the parts after death, we find the vein enlarged, elongated, and thickened, more generally thickened at interspaces. In some instances the coats are unnaturally thin, in others the valves are widely separated; in some they appear too small for the calibre of the vessel, and occasionally we find them ruptured. The superficial veins are, in almost every case, considerably enlarged.

In contemplating the various modes of treatment which have been adopted by those writers who have distinguished themselves for their laborious researches and high attainments, we may conclude that the essential object they have each had in view has been the most efficacious means of partially or entirely destroying the vena saphena. The ulcer dependent on a varicose state of the vein has appeared to them only permanently curable, through the partial or entire destruction of the vein. This appears to have been the object of Sir Everard Home, Sir B. Brodie, MM. Fricke, Velpeau, Davat, Sanson, Bonnet, and others. Sir B. Brodie has devoted much time and attention to this disease,

and has adopted several modes of treatment; he, with Sir Everard Home, applied the ligature, and with some success for a time, when phlebitis occurring, and death resulting, it was discontinued. Mr. Abernethy, considering that the ligature was the exciting cause of the phlebitis, suggested the mere division of the vein; and Sir B. Brodie and others appear to have availed themselves of the recommendation. In many instances irritable ulcers supervened, and in most the benefit was very transient. Sir Astley Cooper, in speaking of the ligature and division of the vein, remarks,—"It was formerly the practice, when the veins were in a varicose state, to tie and divide them; this plan is pursued by many surgeons, but it is one that I have deprecated in my lectures for many years; it is bad treatment, very injudicious, and fraught with great danger. I have seen this operation prove fatal twice, and if I were to state all the cases in which I have known it terminate fatally, I should recount at least a dozen. Another overwhelming objection is, that when it does not prove fatal, its ultimate effects are perfectly nugatory." Whereas Signor Rima, in giving the results of thirty-four operations, by the excision of an inch long of the vein above the first varicose swelling, states that there were—

10	radically cured.
13	much relieved.
6	slightly relieved.
2	not relieved.
2	deaths.
1	under treatment.

I witnessed this operation performed in St. George's Hospital, where every precaution was taken, and the operation done in a masterly style; nevertheless phlebitis came on, which proved fatal on the third day. The subject was about twenty-five years of age and in the height of good health at the time of its performance. This was the only case in which I have seen the excision of a portion of the vein, and therefore do not feel myself in a position to speak decidedly on its value, yet from the relation of several cases, and the table quoted from Signor Rima, we may conclude that it is far from being free from danger.

It was about the year 1818, that Sir B. Brodie adopted a new mode of dividing the vein with the intent of preventing the irritable ulcers consequent on the old method. The operation consisted in passing a thin-bladed knife for some distance under the skin, over the vein, then turning the cutting surface downwards, draw it across the vein, and divide it. In a very large majority of these cases much good appeared to result, and the operation for some time was held in repute; but I believe in almost every instance after a short lapse of time the disease returned, and Sir B. Brodie has given it as his opinion that the operation is not attended with a benefit great enough to justify its performance, and now recommends, as did Sir Astley Cooper, bleeding from the saphena when necessary, and applying a well-regulated pressure and other palliative means.

M. Breschet tried the plan of pinching the vein with forceps, constructed for the purpose; this plan frequently answered the end of obliterating the vein, but often produced sloughing and ulceration, which in time was cured. The process was tedious. M. Sanson also constructed forceps, with blades so broad as to keep the sides of the vein in contact for nearly an inch. He remarks that it is not necessary to compress the vein with a force to induce adhesive inflammation; it is sufficient to compress the vessel so as to arrest the flow of blood through it, when a clot forms, which ultimately becomes absorbed, and leads to a permanent obliteration.

Sir Astley Cooper, in speaking of the treatment of varicose ulcers, says, "The first thing to be attended to is the recumbent posture, in fact this position is indispensable;" he then recommends mercurial washes and bandages. He also recommends the opening of the veins;—"indeed they are so distended that they may be more properly termed lakes than rivulets." He advises the veins to be punctured twice a week, and speaks of the little danger attendant on the operation. He farther remarks, "if the puncture, however, at any time should not unite, but *fret into ulcers*, you must apply Liquor Calcis."

Lallemand, Davat, and Velpeau, applied needles in the manner recommended by Mr. Phillips, of London, for the obliteration of arteries, and with success so far, rendering the vein impervious for some distance of its course; it is a painful operation, and not always successful.

M. Fricke adopted the plan of fixing the vein under the skin, passing through it a needle armed with a strong thread. This was done at intervals of a few inches, in every vein that it was thought necessary to obliterate. The thread was moved daily in the vessel to excite inflammation, and was removed on the third or fourth day. With M. Fricke this operation was successful, whereas with Velpeau it was very unsuccessful, for out of twelve patients inflammation of the vein took place in all; in three of the cases the inflammation was so excessive that the patients barely escaped with their lives, and the twelfth patient died of phlebitis.

M. Velpeau's method of applying the ligature appears to have been so successful in his hands, that I quote his plan more fully. A strong sharp pin with a large head, and a waxed thread, are the only instruments used. The patient is to be placed in such a posture as will render the veins tumid and prominent. The trunk of the vein is now raised up with the fingers, the pin is passed below the ends of the nails, and underneath the vein. It is necessary to protect the finger with a thimble, for the tissues

under the varicose vein are often very hard and resistant. This process must be repeated with regard to every dilated vein; eight, ten, twelve, or fifteen pins may be required from the foot up to the knee, but, generally speaking, three or four are sufficient. When the veins are free and moveable under the skin, it is easy to pass the pins under them; but when they are applied closely to the bones, this is sometimes impossible; it is then necessary to pass a strong pin perpendicularly downwards, and then direct it obliquely under the trunk of the vein. The pins being all placed, are fixed with threads, by twisting the thread in a circular manner round the pins, taking care to draw it tight. The pins and ligatures are not removed before the sixth or twelfth day, when the tissues embraced between them have been destroyed; but even if the *eschar* be not detached at this period, it is well to remove them, as there can be no doubt but that the vein is obliterated. "The introduction of the pin gives very little pain, but the constriction exercised by the ligature is *excessively painful.* Hence you should commence with the highest pin, in order to cut off the nervous communication as much as possible." The tissues embraced by the ligatures mortify and are separated, leaving a sore, which soon heals up. M. Velpeau further states,—"Of more than one hundred patients on whom I have operated by this method, not one has presented any dangerous symptoms; some slight *external phlebitis,* and the formation of some *small abscesses,* were the only consequences of any moment that ensued. Still I always dreaded that such constant success in this matter would be interrupted by an unfavourable result, and my apprehensions have been unfortunately realized. The only *fatal case* occurred recently."

The plan so much extolled by Velpeau I have seen tried on three occasions; the subjects were young and healthy; the operations were performed by my late colleague, Mr. Wainwright, in a most excellent manner. In the first there were slight symptoms of phlebitis, but which required active treatment to allay. In the second case the symptoms of phlebitis were more acute, and it was with difficulty that the patient was saved. In the third case, a troublesome ulcer formed, the varix re-formed, and the operation was not renewed. I would state that one pin only was applied in each of these cases, and that we never ventured on this operation again.

In the year 1834 a gentleman requested me to operate on his leg. He had been quartered in Dublin with his regiment, and had consulted an eminent surgeon there for varicose veins, and a small painful ulcer. The surgeon suggested the propriety of having the vein destroyed by an application of potassa fusa. As I had never seen the treatment adopted, nor did I at the time know that it had been tried, I put the patient off as I best could. On considering the subject, I thought so favourably of the principle, that I determined to give the plan a trial the first opportunity. It was not long before one presented itself, as in the month of August, 1834, a cook applied to me for an old ulcer dependent on varicose veins, whose case I will relate, as it will suffice to show the manner in which the caustic has been applied by me, and will show also the usual course in the treatment of these cases.

Mary Jackson, aged 53, a cook, of full habit of body, has been afflicted with varicose veins for seventeen or eighteen years, and during the last eight years has suffered from a painful ulcer above the inner ankle. This ulcer has been healed two or three times during that period; it frequently confines her to bed, and renders her very inactive and unfit for her work. The ulcer is about the size of a crown-piece; the skin surrounding it is inflamed and hard. After keeping Jackson in bed for two days, and prescribing low diet, I emptied the vena saphena by raising the feet, and passing my hand along the inside of the leg. A piece of adhesive plaster on leather, with an aperture in it of the size of a shilling, was applied over the vein on the inside, and just below the knee. The potassa fusa was freely rubbed on that part of the integument seen within the aperture in the plaster, until it assumed a dark-brown appearance. A warm poultice was then placed over the whole. I was pleased to find that the patient did not appear to suffer much. On the third day after the application the distension of the vein subsided, and the character of the ulcer improved. On the tenth day the slough came away, and by that time the ulcer began to heal. On the patient assuming the erect position, a cluster of veins was still observable, a few inches above the ulcer. The caustic was applied a little above the cluster, with the same result as before. The distension disappeared, and on the twelfth day the slough separated. This case speedily got well, and two years afterwards, on my examining the leg, the ulcer continued quite well, and the veins appeared more arborescent—that is, the minute branches were more observable than natural.

In the case alluded to there was no untoward symptom, and from the result I was induced to persevere in the plan, and have now treated upwards of forty cases in this manner. I have generally succeeded in healing the ulcer in an unusually short time. My only application to the ulcer itself has been a little wet lint; and I have observed the ulcer produced by the separation of the slough, and the original ulcer, heal about the same time. In two cases, at the time of the separation of the sloughs, hæmorrhage came on to a considerable extent. In both instances the patients refused to confine themselves to bed; with these exceptions I never experienced any unfavourable symptom. In one case the caustic was applied in several different places before the patient quite recovered. In this instance the woman had suffered from varicose veins and a painful ulcer for

twenty-three years; the ulcer had been healed several times during that time, but did not remain healed for a month together. This was decidedly the worst case I ever treated on this plan. It is now nine years since the caustic was applied, and during the whole of that period she has continued well with one exception, and then, after a very hard day's washing, and exposure to cold, she had an attack of erysipelas in the leg, which terminated in abscess and ulcers, which were troublesome to heal. After a few weeks' perfect rest she got well, and has continued so. The varix had followed a severe burn, which occurred when she was fifteen years old.

The minimum age of the patients attended by me was 22; the maximum 78. Of the forty-three cases the shortest time of cure was nineteen days; the longest time 147.

10	were cured in a period averaging from	20 to 30	days.
15	„	„ 30 to 40	„
8	„	„ 40 to 50	„
2	„	„ 50 to 60	„
5	„	„ 60 to 70	„
1	„	„ 70 to 80	„
1	„	„ 80 to 90	„
1	. . . . .	took 147	„

In most of the cases one eschar has been sufficient. Occasionally the caustic had to be re-applied in consequence of the slough not penetrating deep enough, so as to destroy the vein, which can be always ascertained by the patient's rising from bed. In several cases the caustic had to be be applied in more than one place, seldom more than in two places, in one instance in nine places. I have met with one case only that baffled this means, and that occurred in an old man, who had gloried in a bad leg with varicose veins for many years; he had travelled the round of several hospitals, and I suspect used means to irritate the ulcers, for invariably when it was about to cicatrize, I found a greenish slough present itself, which rapidly threw back our attempts. This man left the hospital uncured.

Of the cases enumerated there existed a larger proportion of men than women; they were of various ages, from 22 to 78; the stature was generally middle-sized, and their occupations varied. Of these cases only five returned to me with a recurrence of the ulcer, and enlargement of the vein, and then not until after a lapse of two years, and in one instance not until after the expiration of three years, although they were invariably requested to return, in case the leg became again affected. In several instances I have had the means of knowing that the cure has remained good. In hospital practice there is considerable difficulty in retaining a knowledge of patients after they leave the institution; nevertheless, it is only reasonable to suppose, that out of thirty-four cases treated there during thirteen years, all of whom appeared pleased with their recovery, a greater number than five would have returned, if the disease had recurred. A few weeks ago a man (one of the five before alluded to,) applied to me to use the caustic again; he had been under my care two years ago. He stated that the leg had become painful, and that a small ulcer had formed above the inner ankle. On examining the leg I found several knots of veins, and the ulcer was looking irritable. An eschar was made above the highest knot, when the distension subsided, the pain disappeared, and the ulcer healed quickly.

But supposing that this mode of treatment only acts beneficially for two or three years, is it not superior to any other? It is free from danger; there is no difficulty in healing the ulcers; even those of many years' existence yield to it. Sir Everard Home found it necessary to discontinue tying the veins, and Sir B. Brodie and others deprecate the removal of a portion of the vein. The application of the needles, according to Phillips's plan, and needle and ligature according to Velpeau's, has not answered, without occasionally producing inflammation of the veins, and is acknowledged by its inventor as "very painful," and not unattended with danger. Sir B. Brodie acknowledges the inefficiency of his mode of dividing the vein, and with Sir A. Cooper, contented himself with using palliative measures,—such as the elastic stocking and bandages. The great advantage of the caustic, as a means of destroying the vena saphena, over every other method, is the safety with which it may be used, the facility of its application, and comparative ease to the patient. When necessary it can be re-applied, and this too, in several parts of the vein's course. Cases in which there existed great pain from inflammation of the ulcer and indurated integument, after the application of the caustic became easy and healthy.

Mr. Mayo published a case in 1834, in which he cured a varicose state of the veins in the leg by the application of caustic issues. Sir B. Brodie also mentions having applied the caustic potass in a case without any bad symptoms; he does not state why he discontinued its use. And M. Bonnet, surgeon to the Hotel Dieu, Lyons, has been in the habit of using the kali with great success. The rules he gives for its application are as follows:—

1. Many portions of caustic must be applied on the course of the dilated vein, at intervals of two or three inches.

2. The application should not be made, except in those parts of the veins which correspond to the muscles. The only places where it should be applied are on the superior half of the leg, and inferior half of the thigh.

3. The caustic must be applied at least twice at the same points, in order to reach the vein. This supposes that it is necessary, in order to obliterate the veins, to reach and open them with the caustic. In no case

after the first application, which only destroys the skin, and a little cellular tissue, has the flow of blood been found to cease in the veins; and they are never found converted into a hard cord, impermeable to the blood. It is only after being opened that these changes occur. M. Bonnet has not even once seen a tendency in the inflammation to propagate itself along the course of the veins, although three or four applications of the potass had been made on different parts of their course, and in the greater number had opened their cavity; the inflammation was, therefore, in all these cases, limited by the bands of adhesion, and perfectly circumscribed. These results prove that destroying the veins with caustic potass does not expose the patient to the danger of phlebitis, "and," says M. Bonnet, "finding every-day proofs of the innocence of this remedy, I now take no other precau- than that of confining my patients to bed."

It is a question for the consideration of surgeons whether it were better to make a sufficiently deep eschar on the first application of the caustic, so as to destroy the vein, or to apply it a second time, as recommended by M. Bonnet. I have found it necessary in a few instances to apply the caustic a second time, but in a very large majority of them the eschar was sufficiently deep by the first application to destroy the vein, indicated by its becoming converted into a hard cord-like substance. Whenever I found the vein continuing pervious, which is denoted by its continued distension, I re-applied the caustic. I have only found it requisite in ten cases to use the caustic, as recommended by M. Bonnet, at several parts of the vein; in five of these it was necessary to use it in two places; in two it was applied in four places; in two in three places; and in one in nine places. I do not advise its application at intervals of two or three inches at several parts of the vein, as adopted by M. Bonnet. Where the first application is sufficient to take in the vein, it is usually found sufficient for the cure. It may be requisite to apply it in more than one place, but this forms the exception to the rule. When the slough comes away, a healthy ulcer is left, which usually heals by the simplest means, and generally at the same time with the original ulcer.

ON THE PHYSIOLOGICAL ACTION OF INHALED ÆTHER.

By J. Black, M.D., Physician to the Manchester Union Hospital.

The remarkable, and, we may now say, the popular, adminstration of æther, by inhalation, for producing insensibility to pain, during surgical operations, and some idiopathic afflictions of the body, has been put to a very general trial throughout the kingdom. The result, according to the numerous reports, has been, in the great majority of cases, declared satisfactory, and in many cases so successful, that the process has been pronounced in several quarters, as the discovery of discoveries of the nineteenth century, and as one of the greatest blessings to suffering humanity. It is true that some cases have been reported unsuccessful, and a few others have been candidly represented as either fatal in the result, or followed by injurious effects.

Amidst all these generally favourable and exceptionable reports, although mostly given with practical detail, I have, as yet, seen no scientific solution of the *modus operandi* of this novel application of æther on the animal and sentient organism, and scarcely any attempt at a rationale of the process. Some have stated that the physiological action is narcotic; others sedative, while the majority of those who have touched the question, have compared the effects of inhaled æther with those of intoxication from alcoholic liquors, or the Indian hemp.

After so much practical experience of the visible effects of this remarkable process, it may not be considered premature now to examine some of the essential conditions of the question, to see whether we can approach to any fair physiological solution of it.

In the first place we have the chemical substance, rectified sulphuric æther, long known and used in medical practice as a quick diffusible stimulant and antispasmodic. It is a compound of carbon, oxygen, and hydrogen, and has a specific gravity of 0.750 at 40°, and 0.715 at 60°, according to Dumas and Brande. What is its more peculiar property is the density of its vapour, being at the mean pressure and temperature, as 2.58 to air, as=1. The elastic force of its vapour is another property of most important consideration, being at 54°, Fahrenheit=10.3 inches of mercury, at 64°=15, and at 96°=30 inches, gradually increasing in tension, till at 212° it has a force of 240, according to Dalton; it, moreover, boils under a pressure of 30 inches, at 98°, Fahrenheit.

Let us next examine the conditions of the subjective part of the theorem—the animal lungs and body, to see if there is any physiological path for us safely to follow. The human body has a temperature, varying from 98° to 100°, and we may consider the lungs, immediately after expiration, to be about either of these temperatures. The temperature of the æther inhaled has been at various degrees, from what is called temperate, up to 75°. On this difference of temperature depend greatly the physical and other effects of the æther vapour on the tissue of the lungs, and its ultimate force on the sentient brain. According to Dr. Snow, air, saturated with the vapour, at 54°, contains about one third of its bulk of vapour, and at 75° it contains more than one half. The simple result then of inhaling this vapour, at whatever degree of saturation, will be to increase its elastic force or excentric pressure, from 15 to 30 inches of mercury, if it is inhaled at a temperature of 64°. If taken at 75°, at the full point of saturation, the practical increase of elastic force will not be very much less. There can be no condensation of this vapour in the lungs, for even if imbibed in a liquid state, the heat of the body, at 98°, would soon throw it into vapour, that temperature being its boiling point, which is a very curious coincidence.

From these conditions, excentric pressure must be, with greater or less force, made on the air-cells of the lungs; it may be hazardous to calculate the amount

but it must be great. The question now is, upon what tissue is this increased elastic pressure expended to produce the phenomena of *ætherization*, among which, insensibility to physical pain and suffering is the most conspicuous? Is it chiefly or solely through the channel of the blood-vessels or the nerves of the lungs, that this exaggerated pressure or irritation is conveyed to the *sensorium commune?* for it appears that the physiological climax is there exploded.

To solve, in some approximative manner, this point, and to see how far the law of *endosmosis* might be concerned in the first part of the process, I inclosed, at the common temperature, some rectified æther, in a piece of recently killed lamb's small intestine, which, after being firmly secured and made perfectly tight by ligature, was found to weigh two drachms, including the contents, which only filled one half of the cavity to allow of safe expansion. This little sac of æther was, with the assistance of Mr. Hallsworth, apothecary of the Union Hospital, immersed and kept down in a vessel, containing about six ounces of blood, freshly drawn from a healthy adult, and which was placed in another vessel of water, kept at the temperature of 100° Fahrenheit. The sac of æther was gently kept under the surface of the blood by a stiff feather, without agitation, and being withdrawn after ten minutes, was washed clear of blood, and cooled down to its temperature before immersion, when it was found to have lost fifteen grains, or about one-eighth of its former weight. This loss was entirely of the æther, for the gut-membrane was the same as before; it was still tight to liquid æther, and therefore the loss must have been by *exosmose* through the gut-membrane. Besides, the blood at the end of the experiment smelled strongly of æther.

This rude and simple experiment may be taken for as much as it is worth, but I cannot help considering it as very much countenancing the view, independent of a *priori* probability or reasoning, that the vapour of æther, through the elastic pressure which it exerts, permeates the walls of the air-cells of the lungs, becomes absorbed by the blood currents, is thence conveyed directly to the heart, and so quickly carried in a direct stream to the brain. All this may be done in less than ten seconds, according to the experiments of Mr. Blake on the transmission of poisons by the blood-vessels. After the vapour reaches the blood current, its elastic pressure is still kept up, if not increased, by the heat of the heart and other internal tissues. This adventitious force will at most, only increase the reaction of the central organ, and distend, more or less, the elastic calibres of the efferent vessels; but when the distending agent reaches the brain in the current of the circulation, this elastic force meets with a counter pressure in the resisting case of the calvarium; its tension will therefore become increased, and the consequence will be, the cerebral mass will suffer pressure, even to paralysis of some of its functions. This adventitious pressure being, however, occasioned by elastic vapour, and not by fluids, however attenuated they may be, as alcohol, it may not, and does not seem in general to lead to any serious or permanent lesion; in most cases the brain soon becomes relieved by the dispersion of the very permeating vapour throughout the tissues, if not by its decomposition.

Professor Christison mentions two cases where inhalation of sulphuric æther produced,—in one, intermitting lethargy for thirty-six hours, with depression of spirits and lowness of pulse; and in the other apoplexy for some hours, and the person would have perished had he not been discovered. Brande appears no farther acquainted with its physiological effects than that "it produces a remarkable species of intoxication when its vapour is respired, mixed with air."

It is unneeessary to advert much to the actual phenomena that occur after inhalation, as corroborating the views of excentric pressure and distension obtaining in the heart and blood-vessels, with more or less corresponding irritation. We witness, where the process has been successful, frequency and softness of the pulse, swelling and general fulness of the vessels of the neck, head, and face, with laborious breathing, congestion of the eyes, and dilatation of the pupils. It would appear that in many cases, while there seemed to be perfect insensibility to pain, and a suspension of all voluntary movements, yet a consciousness of the surrounding objects and operations remained, rendering this state very similar to that of the mesmeric trance. This appears to be the most difficult part of the question to solve, and requires the most refined analysis for explanation.

Not to leave the solution of this very interesting point altogether unattempted, might not the partial dislocation of nervous function be occasioned by the newly imbibed pressure on reaching the encephalon, being at first and for a time, expended on the base of the brain, which is more immediately in contact or connection with the arteries that convey the blood directly from the heart. The sensory ganglia are here also more exclusively located, and will first suffer suspension of their functions; but if the blood has taken up an undue charge of the elastic vapour, or if inhalation be continued too long, or if the subject is of feeble resistance, the whole parts and functions of the brain will suffer, and enervation, apoplexy, or death, may follow.

Without intruding farther upon your columns at present, I have only to say, that as the whole subject is full of interest, it is very desirable to withdraw it as much as possible from the domain of speculation into that of science; and if the few observations which have here been made tend to provoke some more exact and experimental researches on this engrossing subject, the writer will feel gratified to see the physiology of the matter placed upon a more satisfactory basis than it is at present.

Manchester, March 15, 1847.

ON THE EMPLOYMENT OF NUTRITIVE ENEMATA.

By Kenrick Watson, Esq., F.R.C.S., Stourport.

The following cases may perhaps be interesting to some of the junior members of the profession as shewing the confidence which may be placed in enemas in those cases, in which either from severe injuries of the throat or fauces the power of swallowing is lost, or on account of irritability or exhaustion the stomach rejects whatever is swallowed. I am very

well aware that there is nothing new in these cases, but I am convinced that life may be frequently prolonged by the simple means which were used in them.

Case I.

———, aged 40, was in the fourth month of her pregnancy. She has had seven children born at the full period, and abortion has taken place upon several occasions. Once or twice after the expulsion of the placenta she has suffered from profuse hæmorrhage, and her life has been saved with difficulty. The abortions have likewise been attended by profuse discharges. When pregnant, she has always been apprehensive that she should die from flooding when she was delivered.

Upon the 10th of January, 1847, she travelled for a short distance upon a rough road, which she complained made her feel very uncomfortable, and upon the night of the 12th she was very much alarmed by the appearance of hæmorrhage from the vagina. I saw her at noon, a few ounces of blood had been discharged, perhaps about four, but it had ceased. It was evident from the state of the os uteri that abortion would take place, and the usual precautions as to posture and temperature were had recourse to. As she had a violent cough, a few grains of hemlock and Dover's powder were directed to be taken at night, and a solution of Epsom salts in infusion of roses in the morning.

No material change took place until the 23rd, when about nine at night a considerable discharge took place. I immediately plugged the vagina, applied ice externally, and gave her a dose of ergot of rye. She began to yawn frequently, and shortly afterwards the pulse ceased at the wrist. Brandy was freely administered with ammonia and opium; but the pulse very shortly became imperceptible, though during the space of an hour it revived a little occasionally from the stimulus of the brandy. Warm bottles were applied to the extremities and to the epigastric region, and mustard plasters to the feet and cardiac region. The hands and arms were deadly cold; there was no pulse at the wrist; the carotids beat firmly, and the brain retained its integrity except for a few minutes, when she complained of being deaf. About this time slight uterine pains occurred, followed by vomiting, the plugs were forced from the vagina, and the fœtus and secundines expelled. A pint of milk, in which an ounce of isinglass was dissolved, was injected, and directed to be repeated every six hours. The anodyne was repeated.

About three o'clock she began to vomit, and from this time till nine on the night of the 24th nothing remained upon the stomach, and there was no pulse at the wrist during the whole of these eighteen hours.

At the suggestion of Mr. Cole, of Bewdley, who kindly assisted me in the treatment of the case, it was proposed to have recourse to transfusion, but the objections of the patient were so decided that it was considered that the alarm might be immediately fatal to her.

About three o'clock vomiting again took place, and from this time the stomach retained no nourishment; the injections were well retained and were regularly repeated. The natural warmth gradually but regularly returned, and an effervescing draught remained upon her stomach, and then a tea-spoonful of brandy, and during the night three spoonfuls of beef-tea.

In the morning the pulse could be counted, about 130. She continued to take nourishment, the injections were continued,—sometimes of broth, at others isinglass and milk; her pulse became regular, and she gradually recovered.

Case II.

Ann Randal, aged 70, after having made three previous attempts at self-destruction, cut her throat with a razor upon the 16th of April. The os hyoides was separated from the larynx; there was no large vessel divided, and the patient was in a quiet manageable state. Two stitches were passed through the integuments, and the chin fixed in a proper position. The discharge of saliva from the wound was so great that no dressing could be retained, and the discharge was removed from time to time by a sponge.

As she had quite lost the power of swallowing, a pint of milk was conveyed into the stomach through an elastic tube, and an enema, containing an ounce of isinglass, dissolved in a pint of milk, was directed to be injected every eight hours.

The next day she objected so very much to the passing of the elastic tube that I determined to try how long she could be supported by enemas, and from that day, until the 16th day of May, she never swallowed a morsel or drop of any description, unless it was saliva; on that day she swallowed a little milk, which was daily increased, but still she continued to depend principally upon enemas, as a means of support, for several weeks. No union took place between the lips of the wound, and it granulated so very slowly that she continued under treatment until the 26th of July.

During the whole of this period her general health continued good. The enemas occasioned no irritation, and occasionally it was necessary to give an aperient enema. In case the bowel should become irritable, an injection of starch and opium was directed to be used.

Stourport, February, 1847.

CASE OF FALSE PUPIL.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

The accompanying case occurring at Southam Infirmary, appears to me to be of some interest in reference to the physiology of the iris, with which, notwithstanding all that has been done, we are hardly yet sufficiently acquainted. Should you think it likely to gratify your readers, it is much at your service.

I am, Sir,

Yours truly,

HENRY LILLEY SMITH.

Martha L——, aged 13, admitted Feb. 22nd, 1847. The right eye presents the following appearances:— The pupil is not correctly circular, seeming as if

flattened on its superior margin, but its form to a certain extent varies with the degree of dilatation. The pupil contracts under the influence of light, although more sluggishly than in the healthy eye; it expands freely on the application of belladonna.

At the upper part of its ciliary circumference the iris is detached, forming a *false pupil*, which, when most dilated, is in length about the eighth of an inch, of a fringed irregular form, resembling the opening made when a curtain is partially torn down. This false pupil varies much in size, being scarcely observable when the natural pupil is dilated, but enlarging when the natural pupil contracts. The false pupil is also, though not to a great extent, affected by the application of belladonna.

When the natural pupil is covered as much as possible, and the upper eyelid raised, light can be discerned through the false pupil.

The vision of the right eye is nearly lost, so that she can rarely distinguish the bars of the window, and on being shown a book printed in large type can make out only a number of black spots. No opacity is discernible in or behind the lens. On using the cat-optrical test, the three images are seen. Has no pain, ocular spectra, nor muscæ volitantes.

This state is the result of a blow from a stone thrown at her when an infant. She has had no useful vision since, and lately the obscurity has, she thinks, increased.

There is strabismus convergens of the right eye. The left eye is healthy; the iris is of the same colour as that of the right, and the eye being opened or closed produces no effect on the opposite eye.

CASE OF POISONING BY THE TINCTURA FERRI SESQUICHLORIDI.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I know of only one recorded case in which an accident precisely similar to that which I am about to relate has happened; and as in that one the result was different, I think you may consider the following worthy of insertion in your valuable Journal.

Yours ever faithfully,

THOMAS EDWARD AMYOT,

M.R.C.S.L, &c,

Diss, Norfolk, March 13, 1847.

Mrs. ———, a young and healthy married lady, swallowed one drachm and a half of the tincture of muriate of iron, in mistake for a common aperient draught, which was standing on the same table, on the morning of December 15th, 1846. I should observe that she had taken an aperient pill on the preceding evening, which, together with the draught, was ordered for a slight mumpy inflammation from which she was suffering. Immediately after swallowing the tincture she threw back the greater portion of it, and violent retching continued for some time. An emetic, and warm milk, sugar, and water, were shortly afterwards given, but owing to the great swelling of the glottis, but a small quantity of them was swallowed, and their effects were therefore inconsiderable. Violent retching and coughing, especially on attempting to swallow, recurred at intervals.

Mistura Cretæ was given with a view of neutralzing the excess of hydrochloric acid in the tincture, and of converting some portion of the salt of iron into the less active *carbonate*, but probably none of it reached the stomach. Leeches were next applied to the throat, and mustard poultices to the stomach and between the breasts, with relief to the symptoms. Heat and dryness of the throat, and pricking sensation along the course of the œsophagus and stomach continued, however, and in the afternoon a quantity of dark grumous blood was vomited. The bowels had acted twice in the day, (probably from the aperient pill,) but the motions were not seen. A dose of Liquor Opii sedativus was given at night, and the patient had some sleep.

December 16th. Symptoms much as yesterday; pulse 100 to 110, irritable; tongue slimy and brown towards the root. A large motion, knotty, black, and with much mucus. Continue chalk, soda water, milk food, mucilaginous drinks, and opiate at night. The vomiting continues. Scarcely anything swallowed.

17th. Not much sleep last night; retching and tenesmus to-day, but no motion; catamenia appeared; pulse the same; tongue a little cleaner. Repeat the opiate if necessary.

18th and 19th. Symptoms much the same; on the 19th, however, the patient was much troubled with cough, and expectoration of clear frothy mucus. A mustard poultice was applied to the course of the trachea and œsophagus; and the bowels having been but very slightly moved on the 18th, with a knotty and dark motion, an ounce of castor oil was used as an enema, and produced four motions, the last of which was loose, plentiful, bilious, and untinged by iron. During the last two nights the patient has slept but little.

31st. Since the last report no unfavourable symptom has taken place; occasional injections of castor oil have been resorted to, and the diet has been most strictly limited to arrowroot, sago, milk, broth, and light farinaceous puddings. To-day a few oysters were allowed. My reasons for insisting on this strict observance of diet will be understood by any one who will read Christison's case.

January 15th, 1847. All has been going on well, and the patient may be considered quite recovered. Two days since a little blood was seen in a motion, but there is every reason to believe it proceeded from hæmorrhoids.

March 13th. Quite well.

Remarks.—The case mentioned by Christison and quoted by Beck, was that of a gardener, who swallowed exactly the same dose of the same preparation as in the above instance, but he seems to have retained it for a longer time on the stomach. In three weeks he returned to his work, but in two weeks more he became emaciated, cadaverous, suffered from pain and *costiveness*, and died six weeks after swallowing

the tincture. It is stated that remedies were applied, but their nature is not mentioned. The pylorus was found "greatly thickened with a cicatrized patch, three inches long and two broad, and another large inflamed spot."

Now although Christison mentions this tincture as a *violent poison*, it is not spoken of in any of the poison charts I have seen, and the only direction as to treatment I have met with is in Pereiras's "Materia Medica," where "*the same as for the mineral acids*" is advised. (I should say that I have not Mr. Taylor's book at hand.)

But besides the treatment applicable to poisoning by the mineral acids, viz., the administration of chalk, magnesia, the carbonated alkalies, milk, white of egg, &c., the symptoms above related seem imperatively to call for the long continuance of mild diet, the repeated use of castor oil enemata, and great watchfulness of the case for at least a month or six weeks; or in other words, *the disposition to obstinate costiveness, even long after the patient seems convalescent, and the progress of inflammation and ulceration in the pylorus five or six weeks after the poison has been swallowed, should be well borne in mind.*

I should have observed, that in the case of the lady detailed above, the catamenia appeared before their proper time, and were possibly hastened on by the iron; and that owing to their presence and to the black colour of the motions, it was not easy to say whether any blood came from the bowels. I *think* there was some in the first evacuations.

[Mr. Taylor mentions a case reported to the Westminster Medical Society, in November, 1842, where a girl, aged 15, five months advanced in pregnancy, swallowed an ounce of the tincture of muriate of iron in four doses in one day, for the purpose of inducing abortion. Great irritation of the whole urinary system followed, but this was speedily removed, and she recovered.—Ed.]

ON SIMPLE ACUTE INFLAMMATION OF THE MEMBRANES OF THE BRAIN IN INFANTS.

By Dr. Rilliet, of Geneva.

(Translated for the Provincial Medical and Surgical Journal.)

(Continued from page 153.)

MORBID APPEARANCES IN OTHER ORGANS.

Spinal Marrow.—The inflammation sometimes extends from the membranes of the brain to those of the spinal cord. It is to be regretted, however, that in the cases of autopsy which we have at our disposal, the examination of this part has been exceptional. [The author refers the reader for information on this point, to his "Traité de Maladies des Enfans," t. i., p. 679.]

Thoracic and Abdominal organs.—The most important fact which is elicited by the examination of these ogans in cases of true meningitis is, that tubercles are never met with, although they are universally present in meningitis of the base. Thus, in seventeen autopsies, we did not once meet with them. The same fact appears from the analysis of the cases reported by Senn, whose observations are the more valuable, as the results are given without any pre-conceived idea of the nature or pathological relations of the disease. We therefore consider it justifiable to propound the pathological law,—*that general meningitis, and meningitis of the convexity of the brain, attacks only non-tuberculous subjects; while inflammation of the base, without co-incident affection of the membrane of the ventricles, is exclusively a disease of the tuberculous habit.*.

This law is true in the majority of cases; but as there is no absolute law in pathology, so we may possibly meet with some few exceptions. It may happen, for instance, that inflammation is excited in a tuberculous subject by mechanical injury, purulent absorption, &c., and that in such a case it assumes the characters of true meningitis; but we are convinced that if inflammation arises spontaneously in the tuberculous subject, it will attack the base of the brain; in the non-tuberculous, its convexity, or the entire periphery of the brain.

III. Symptoms.

As the symptoms which are manifested by the nervous system are the most important at all periods of infancy, we shall make them our first consideration.

Headache is a constant and early symptom in children above the age of two or three years; below that age it is often absent, especially in the secondary forms of the disease. This symptom either sets in simultaneously with the fever and vomiting, or precedes these by a day or two. It is confined to the front, and of great intensity, much greater than either in typhoid fever, or the tubercular affection of the brain. Its duration is variable, but seldom beyond the third day.

Intelligence.—The disturbance of the intelligence is also an early symptom, and is never wanting, whether the inflammation be primary or secondary, or at any age. In children of four or five years, disorder of the mental faculties precedes the lesions of motility; the reverse is the case in young infants. The mental disturbance is usually first manifested in an appearance of anxiety and inquietude. The child cannot rest, but changes its position unceasingly. It either refuses to answer questions altogether, or its replies are short and peevish. Subsequently delirium of a violent kind ensues. In some cases, chiefly in very young infants, somnolence or coma precedes the agitation, but most commonly the coma follows the delirium, or alternates with it. As the disease progresses the torpor predominates.

Disorders of Motility.—The most common of this group of symptoms are convulsions. In young infants they are frequently the earliest in the series, and are then severe and repeated. In six infants of from four months to two years of age,—in three, convulsions were the first symptoms; in two, they appeared at a later period; in one, six days before death. In older children convulsions are seldom observed at the

commencement, but are commonly witnessed two or three days before death, or are the immediate precursors of dissolution. They are more commonly partial than general, and are not so uninterrupted in their succession as in younger subjects.

Other disorders of the motor functions replace convulsions when these are absent, or succeed to them when they disappear. Thus in some cases, rigidity of the limbs is noticed during the first or second day; in others, a more or less perfect hemiplegia occurs. Some of these phenomena, such as rigidity of the trunk, with drawing backward of the head, are probably to be referred to an extension of the inflammation in the membranes of the cord.

Organs of Sense.—Intolerance of light and noise exists from the commencement. At a more advanced stage there is strabismus and contracted pupil; still later the pupil is largely dilated and insensible.

Countenance.—In the commencement of the disease, the face is alternately flushed and pale; it then bears an expression of haggard anxiety, or of dulness and stupidity. The child appears to fix its gaze for a few moments upon some object, and then relapses into a vacant stare.

Circulation.—There is always more or less febrile disturbance; the pulse is quick, and the surface hot. Occasionally there is an appearance of remittence in the fever, with concomitant variation in the pulse. In general, a fluctuation in the pulse is a constant symptom. [The author admits that he wants more information on the characters of the pulse in the cerebral diseases of children. He might have found much that he requires in English works on these affections, especially in those of Cheyne and Abercrombie.]

Respiration.—The respiration is generally irregular, and sighing. In some cases it is very rapid.

Digestion.—It is seldom that vomiting is absent in primary meningitis of children above the age of four years. This symptom generally appears on the first or second day, and is spontaneous and frequent. In some cases it continues without respite till the close of the disease. In younger children, and in some cases of secondary meningitis, vomiting is absent. Constipation is a common symptom, but it is neither so common nor so obstinate as in the tubercular form of the disease. As death approaches the belly becomes retracted.

(*To be continued.*)

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF WILLIAM SANDS COX, ESQ.

By Peter Hinckes Bird, one of the Resident Medical Officers.

(*Continued from page* 154.)

Case XXVI.

CATARACT.

William Stephenson, aged 63, iron-roller, admitted April 16th, 1846, into the Queen's Hospital, under the care of Mr. Sands Cox. He states that the sight of the left eye has been lost for nearly two years, and that of the right eye ten weeks. The sight left them both by degrees; was very good previously. Has always been a healthy man.

Present State.—The lens of the left eye presents a dull grey colour, marbled with amber, is of small size, and convex; the margin of the pupil forms a blackish, not quite circular, ring round it; that of the right eye is of a dull-grey glistening colour, with streaks upon it; it is also small, and appears convex; pupil as in the other eye. He can see the lights of the windows in the ward, but cannot distinguish the bars between them, while objects appear misty; cannot see his hands without they are placed in the light; can see them better when placed on one side of the eye; can see the blaze of a candle, which appears misty, but cannot see the candlestick; can distinguish black from white. He complains of no pain in the head or eyes; general health good.

Ordered to have the extract of belladonna applied round the eyes in order to dilate the pupil.

May 9th. Since last report he has had the belladonna regularly applied, but has experienced no relief from it; the pupil is very slightly dilated.

Ordered to have the following lotion dropped into his eyes:—R. Extr. Belladon., gr. v.; Aquæ, oz. j. M. Fiat Lotio.

16th. The drops have been applied regularly, but the dilatation of the pupil is scarcelyif all increased.

23rd. Has continued the use of the drops; the dilatation of the pupil is slightly increased; however, he sees no better.

June 10th. The extract of belladonna has been assiduously applied round the orbits, and the use of the drops has been persisted in, but with no apparent improvement to the sight, or increased dilatation of the pupil.

July 12th. It was the intention of Mr. Cox to have operated this morning, but the weather is at present so exceedingly warm that it was thought proper to defer it for a short time.

August 5th. Mr. Cox operated this morning in the following manner:—The patient being placed in the recumbent position on the operating table, the eye-ball being held steady by an assistant, the left eye was first operated on. The needle was introduced through the sclerotic, about a line and a half from the margin of the cornea, and directed into the posterior chamber of the eye, immediately behind the lens, so as to be visible through the pupil, lacerating the capsule, and depressing the cataract; the eye was slightly opened and the patient stated he could see. The right eye was operated on in the same manner, immediately after the left. The anterior surface of the lens had contracted adhesions with the uvea, which were broken down; the eyelid was also elevated, and the patient declared he could see.

Ordered to be carried and put to bed; to be kept in the dark and quiet; to have also a compress of linen, damped with a cold lotion, applied on each eye. He bore the operation remarkably well.

6 p.m. Complains of pain in the eyes, especially in the left.

6th. Complains of great pain, described as sharp, shooting, in the right eye, extending to the back of the head; also of pain in the left eye, more severe than yesterday; tongue furred; pulse rather quick.

7th. There is a great deal of inflammation in the right eye, but the pain is not so severe; no pain in the left eye; can see well with it, but not so with the right.

10th. Has had an attack of the English cholera, which is now very prevalent; it was soon checked by Mist. Cretæ, with Tinct. Opii. Feels to day quite comfortable; bowels comfortable. Continue the cold applications.

14th. Can see quite well with the left eye, which is, however, rather weak; the conjunctiva of the right eye is still inflamed; can see but very little with it. To keep the room rather lighter. Bowels comfortable; sleeps well.

18th. Sight of the left eye stronger, much improved by the aid of convex glasses; the conjunctiva of the right eye is still inflamed; he can see but very little with it, as the lens has come forwards, and occupied the place of the pupil; health good.

Sept. 1st. Sight of the left eye improved, that of the right one much the same; health very good.

The capsulo-lenticular cataract, of which the above case presents an instance, is generally of large size, and it is therefore the opinion of Beer,* that the liquor Morgagni in an altered state may likewise often contribute. It is by no means uncommon, and it is attended with the following characteristic symptoms:—The colour of the opacity close to the uvea is partly chalk white, partly like mother of pearl, and in many cases both these colours can be distinctly seen disposed one over the other; that of mother of pearl, however, being always most superficial. In this case it was marbled with an amber colour. Exposing of the eye to the most vivid light scarcely causes any motion of the iris, but the pupil is circular, without any angles in it. After the application of belladonna the pupil is long in returning to its former diameter. In this case the pupil formed a line round the cataract, and could not be dilated by the constant application of belladonna. It is not unfrequently the consequence of a slow inflammatory process in the iris, the lens, and its capsule.

Old age may be regarded as one of the predisposing causes of cataract, inasmuch as the disease is of most frequent occurrence in advanced life. Of 500 cataract patients, treated by Fabini, 268 were males, and 232 females; and the ages of these individuals were as follows:—

From 1 to 10 years	14
„ 11 „ 20 „	16
„ 21 „ 30 „	18
„ 31 „ 40 „	18
„ 41 „ 50 „	51
„ 51 „ 60 „	102
„ 61 „ 70 „	172
„ 71 and upwards	109
	500

* Lehre von den Augenkrankheit.

Beer assents to the general correctness of this opinion. The cataract of old people generally attacks both eyes within the period of a few months. In this case more than a year elapsed before the other eye was affected.

In doubtful cases the nature of this affection is sometimes elucidated by its history. Cataract forms without any uneasiness in the eye or head, or any disturbance to the health; glaucoma and amaurosis are often preceded and accompanied by various uneasy sensations and functional disorder.

It was the doctrine of Wenzel, that persons frequently exposed to strong fires, and above the age of forty, were more liable to cataracts than other individuals. The preceding case seems to corroborate this opinion, for from the nature of his occupation, the patient was much exposed to the strong fires of the works. It is sometimes observed to be hereditary. In the *Provincial Medical and Surgical Journal* for August 19th, 1846, an instance is related, in which it occurred in the males of three generations.

The operation is now regarded as the only means of affording any rational hope of restoring the eye-sight of patients afflicted with cataracts. Speaking of genuine cataract, Mr. Lawrence* delivers his belief that no external or internal medicine, with which we are at present acquainted, can alter the condition of the opaque lens and capsule. Dr. Mackenzie† believes that most of the alledged cures have, in all probability, been either instances of mere fibrinous effusion on the surface of the capsule, or else cases of ruptured capsule, in which the removal of the opaque lens has been effected by the solvent power of the aqueous humour; while on other occasions it is scarcely to be doubted that no affection of the lens or its capsule existed, but that glaucoma, with incipient amaurosis, was mistaken for cataract, and submitted to certain modes of treatment, which not unfrequently prove efficacious in restoring to a certain degree the sensibility of the retina.

The concurrent testimony of almost all writers upon the subject tends to prove that the restoration to sight has sometimes been effected in the most hopeless cases, I therefore side with the opinion of Mr. Lucas,‡ that in all doubtful cases, an operation should be tried as a remedy by no means violent or hazardous. When there are cataracts in both eyes, some authors are of opinion that there is no reason why one should not be operated on immediately after the other. If division of the cataract is the operation to be performed, Dr. Mackenzie approves of operating on both eyes at the same time; if extraction, then he deems it best to await the result of the operation on one eye before touching the other. In this case one was operated on immediately after the other.

According to Beer, when the cataract is very firm, or moderately so, both depression and reclination can only be a palliative remedy, for he says that none of these cataracts, after the operation, can be dissolved

* "On Diseases of the Eye," p. 44.
† "On Diseases of the Eye," Edit. 2, p. 698.
‡ "Medical Observations and Inquiries," vol. vi., p. 257.

and absorbed, but must remain in the eye as a foreign inorganized body. He also states that he has carefully examined the eyes of persons after death, on whom depression or reclination had been practised, in some instances, more than two years previously; but in almost all the examples, the lens was found firm and undissolved, or at most only diminished, with or without its capsule. He saw an instance in which a cataract rose again after it had been depressed thirty years' previously; when extracted it was found to be almost ossified. In old persons absorption is exceedingly languid, and the lens often very hard. We know, however, from the observations of an infinite number of the highest authorities in surgery, that if in addition to reclination and depression, the cataract is broken piecemeal, this is not the case, but that they are soon absorbed.

Too much should never be attempted to be done at one time in any mode of couching, for its repetition may be safely and advantageously be put into practice again and again. Mr. Hey* states that he couched one eye seven times before perfect success was obtained. A bolder use of the couching needle is sometimes made than the delicate structure of the eye warrants; when this is done, the structure of the eye is sometimes so impaired, and the consequent inflammation so violent, that the restoration to sight is utterly prevented. Reclination is to be preferred when, together with the objections to extraction, the surgeon has to deal with a fully-formed, *very hard, lenticular*, or *capsulo-lenticular, cataract*, or, with a case of the latter kind, complicated with partial adhesions to the uvea.

When the cataract is partially adherent to the uvea, Beer recommends an endeavour to be first made with the edge of the needle, (which is to be introduced flat between the cataract and the uvea, above and below the adhesions,) to separate the adherent parts before the attempt at reclination is made.

* "Practical Observations on Surgery."

PROVINCIAL
Medical & Surgical Journal.
WEDNESDAY, APRIL 7, 1847.

A lamentable instance of neglect and consequent loss of life, in which the names of some medical practitioners are mixed up, has lately occurred at Birkenhead. The sufferer was a poor woman in child-birth, and the case became the subject of inquiry before the Coroner's Court. An account of the inquest has been published in one of the Liverpool papers, headed "Alleged Misconduct of the Faculty in Birkenhead," from which it would seem that several medical gentlemen had been applied to and that two had seen the unfortunate woman, but had declined undertaking the charge of the case gratuitously. One of these gentlemen subsequently consented to act on promise of payment, and on finding that the case was a difficult one, procured also the assistance of another practitioner, (Mr. Stevenson,) by whom, after a consultation, the poor woman was delivered. The child was born dead, but the mother appeared to be doing well. Delirium, however, shewed itself on the following morning, recurring at intervals, and in a few days the patient sank. The following verdict was returned by the jury:—"That the deceased died from puerperal mania, or child-birth; but the jury cannot separate without expressing their regret that more prompt and efficient aid was not rendered by the medical men in attendance on the deceased; at the same time they beg to thank Mr. Stevenson for his prompt attention to the deceased when called upon to do so."

It should be stated that the gentleman who consented to take charge of the case called in the evening, and again on the morning after delivery, but not receiving the promised payment declined farther attendance.

We have no intention of discussing the conduct of the medical men who stand implicated with this proceeding. We have not the means of knowing how far the published statement is correct, and judging from the animus shown in the selection of the heading prefixed, we are not disposed to place much reliance upon it; at the same time we would not be understood to screen the medical men from the consequences of the non-fulfilment of the moral obligation which lies upon them to assist a suffering fellow-creature to the extent of their power.

The occurrence, however, is an instructive as well as a distressing one, and there are other parties who may derive a lesson, and may merit reproof, to the full as much as the medical practitioners whose names are called in question. The poor woman it seems fell a victim to the consequences of a natural process, requiring the assistance of a professional man, not on the moment be it observed, but of the necessity for which she and her friends must have been cognizant for months, and yet no provision for obtaining such assistance is made beforehand, and the medical man, whose time is his estate, and his exercise of his professional calling his means of subsistence, is expected to *give* that relief immediately when demanded, and censured by the public for non-compliance. We should be glad to know on what grounds, as far as the public is concerned, he is answerable to the demand on his time, or amenable to the reproof so liberally bestowed? Why is he to be publicly reproved for not bestowing his guinea in the exercise of his calling any more than any individual juryman, or other person, who might have the means at his disposal, for not himself handing out the fee, and thus bespeaking and requiting the service performed.

Let the circumstances of the case be changed, and others unhappily in this day of far greater frequency substituted, and let the inquest be supposed for one moment to have been into the cause of death of an individual or a family, who may have fallen a sacrifice to want of the common necessaries of life; would the jury venture to record a regret that more prompt and efficient aid had not been rendered by any baker or other provision dealer, at whose hands relief might have been sought, or would the account have been headed in a public newspaper "Alleged Misconduct of the Provision Merchants of Birkenhead," or of Liverpool, or of any other place in which such an unhappy event might have occurred? Would they not rather have lamented that the parochial or borough authorities — that is, the public authorities — the authorities to the support of which the public contributes, and over the efficiency of which they have the right of control, had not been more vigilant in the discharge of the duties assigned to them. We deny altogether the right of juries thus to censure the conduct of private individuals, or to dictate the scale on which their benevolence should be exercised, and we greatly question whether there was one individual in the court then present, the medical men excepted, who would not have resented the being called out of bed to give hours of attendance in a case requiring assistance, for which previous provision should have been made, to say nothing of contributing his guinea, or the equivalent of it, on the spot. It is true we find them liberal of their thanks to Mr. Stevenson, for the gratuitous exercise of his professional skill and attention on the occasion, but no expression of willingness on their own part to contribute any portion of their substance towards sharing with Mr. Stevenson the work of benevolence to which he had been devoting his valuable time and his professional skill.

Once more, we are desirous that the tenor and intent of the preceding observations should not be misunderstood. God forbid that the time should ever arrive when the medical profession is not open, heart and hand, to the call of the afflicted, and willing to afford with genuine disinterestedness, all the aid and consolation—professional or otherwise—in their power, to any one who may ask it; but let not the public claim *as a right* from medical practitioners, that professional assistance which it is the duty of the public themselves to see shall be provided for those who stand in need of it, and for which it is equally the duty of the public to see that the professional man who renders it is equitably and liberally remunerated.

Review.

An Essay on the Tongue in Functional Derangement of the Stomach and Bowels, and on the Appropriate Treatment, &c., &c. By Edward Williams, M.D., Cantab., Senior Physician to the Essex and Colchester Hospital. Second Edition. London: 1846. 8vo. pp. 236.

In the examination of patients, under whatever disease they may be suffering, there are no two classes of symptoms more generally inquired into than those presented by the pulse and the tongue. Yet has the former of these—the pulse, been characterized as *fallacisima res*, and the indications afforded by the latter—the tongue, are anything but certain or well-defined. It is true that there are a few prominent characteristics presented by the tongue in various diseases which are strongly marked,—such as the strawberry-tongue of scarlet fever, the thick white coating presented in common continued fever, and the brown, dry, and tremulous state of the organ in typhoid and irritative fevers; but these are indications of a general state rather than of any precise local affection or derangement of the digestive organs, the condition of which the tongue has been supposed especially to point out. To determine, therefore, whether the commonly received opinions as to the indications afforded by the tongue in cases of gastro-intestinal disease are correct,—whether the appearances presented by the tongue can in any case enable us to ascertain the character or type of the local affection, and its precise seat,—is highly desirable, and the attempt here made by Dr. Williams to accomplish this object, in reference to functional derangement of the stomach and intestinal canal, is worthy of every commendation.

It must have occurred to every observant medical practitioner, to notice cases of urgent dyspepsia in which the tongue presents little or no deviation from the state of health, and again to find the same organ foul and variously coated with vitiated muco-secretions without any corresponding general disease or local gastro-intestinal affection. The indications afforded by this organ, therefore, are no more singly to be depended on, than are those afforded by the pulse. This is only one instance among many others, that no single symptom or class of symptoms, however useful in directing the attention towards particular organs or conditions, can be safely trusted as pathognomonic of disease. An examination of the numerous tables with which Dr. Williams has illustrated his work, affords ample proof of the justice of this remark. It is only then by the numerical method, here as elsewhere, that we can arrive at the *comparative* value of any particular character or symptom, as indicative of any special condition. No one character it would seem, is *absolute*. The most general may be occasionally absent when the disease which it is presumed to mark

actually exists, or occasionally present when the morbid condition itself does not exist.

We now turn to the essay of Dr. Williams, to ascertain the results at which he has arrived, from an examination conducted on these principles, of the state of the tongue in functional derangement of the stomach and bowels. The work is divided into three parts :—The first part treats of the tongue of gastric functional derangement; the second, of the tongue of intestinal functional derangement; the third, of the tongue of organic change of the lungs and heart.

Previously to referring to the conclusions drawn from the tabulated cases, it should be observed that the author attaches great importance to the state of the papillæ. On a review of his cases he found that "the tongue presented itself under two principal aspects, when the papillæ were developed, and when they were not observable." Farther, it was noticed, "that when the papillæ, especially the filiform and tuberose, were prominent or florid, the gastric symptoms were the most prevalent;"—"that the stomach was especially affected when the filiform or tuberose papillæ were developed; hence 'the tongue of gastric functional derangement,'" and, again, "that disturbance of the intestinal canal was accompanied with certain appearances of the tongue, the papillæ not being observable, and thus originated the 'tongue's aspect in functional derangement of the intestines.'"

In the sixth chapter we find described the appearances of the tongue with a florid, or anemic, or a prominent state of the papillæ, as deduced by Dr. Williams from the tabulated results of his observations :—

"*A Florid Tongue.*—A florid and clean state of the tongue, the papillæ being florid, anemic, or prominent, was attended with gastric symptoms, as pain, nausea, vomiting, acidity, and flatulency; also a sensation of gnawing or faintness, and a sinking feel at the pit of the stomach. The head was but slightly affected, and then only occasionally. Fugitive pains were especially remarked, with an erect state of the pyramidal papillæ.

"When the tongue was florid and furred, gastric symptoms invariably accompanied a florid state of the papillæ; headache was confined solely to the filiform papillæ, and fugitive pains attended the prominent state of the pyramidal papillæ.

"The tongue being florid, furred, and tremulous, showed no decided symptoms, excepting with the florid filiform papillæ, with which giddiness, gastric pain, and nausea, were present, fugitive pains solely accompanying the pyramidal papillæ.

"With a florid and tremulous tongue, head and gastric symptoms were felt when the filiform and tuberose papillæ were florid. The head and gastric pains were more acutely complained of with a prominent state of the pyramidal papillæ, fugitive pains solely accompanying the latter papillæ.

"It seems, therefore, that when the tongue was florid, as florid and clean; as florid and furred; as florid, furred, and tremulous; as florid and tremulous, the papillæ being florid, anemic, or prominent, that gastric pain or irritation was almost solely and invariably complained of, with the further addition of fugitive pains when the pyramidal papillæ were erect."

In the same manner, it is observed, "that when the tongue was anemic, as anemic and clean; as anemic, clean, and tremulous; as anemic and furred; as anemic, furred, and tremulous, the papillæ being florid, anemic, or prominent, that gastric pain or irritability was chiefly complained of, the head symptoms being slight, and only occasionally felt, fugitive pains attending the prominent state of the pyramidal papillæ,"—and "that a furred, or a furred and tremulous tongue, the papillæ being florid or prominent, not anemic, was accompanied with gastric irritability, and occasional headache; and with fugitive pains, the pyramidal papillæ being prominent."

"The tongue being tremulous, the papillæ being florid, was accompanied solely with gastric symptoms. An anemic or prominent state of the papillæ not being observable under such lingual aspect."

The preceding quotations will afford some idea of the manner in which the author has carried out his object. After the same manner are described other aspects of the tongue, the tabular record being first presented, then the numerical summary, and lastly, the deductions; some observations on the indications of treatment being occasionally appended. How far the more extended experience of the author, and the observations of others who may take up the subject, may tend to establish, define, or modify, the conclusions arrived at, time will show best. It is obvious that Dr. Williams has bestowed no ordinary pains in the observation and recording of his facts, while by throwing them into a tabular form, and indicating the results deducible from them, he has made them readily accessible for the purposes of study and comparison to all who may feel interested in the subject.

We have only farther to observe in commending the work to the consideration of our readers, that the large print, interspacing, wide margins, and occasional blank pages, however refreshing in these days of small type and crowded pages to the wearied eye, are perhaps scarcely what the nature of the subject called for.

Proceedings of Societies.

SHEFFIELD MEDICAL SOCIETY.

Ninth Meeting, January 21st, 1847.

The President, G. TURTON, Esq., in the Chair.

Mr. Jackson laid on the table Hodgson's Engravings of Diseases of the Arteries, in which was a sketch of diseased valves, very much resembling the valves of a heart which was exhibited at one of the early meetings of this session, and reported in the Journal; also Freers' work "On Aneurism."

Mr. James Taylor, of Ridgeway, exhibited a truss, made by himself, which he considered an improvement on one made and exhibited by him to the Society three or four years ago. The improvement consisted in the spiral spring being made conical, and applicable to both sides of the body.

Mr. Thomas exhibited an apparatus for the inhaling of æther.

Dr. Branson exhibited two drawings made by himself, representing the air-cells in the lungs of a sheep.

RHEUMATISM; PERICARDITIS.

Dr. Branson also exhibited the heart of a painter, aged 45. The pericardium was universally adherent, and the heart itself large. The lungs were highly congested and their edges emphysematous. The patient was admitted into the Infirmary, suffering from a second severe attack of acute rheumatism, the former one having occurred five years previously, since which time he had been subject to cough and difficulty of breathing on exertion. The sounds of the heart were very feeble, but no bruit could be heard. On the Sunday week after his admission, he was suddenly attacked with frightful dyspnœa; the rheumatic symptoms as suddenly subsided. The dyspnœa continued unalleviated by treatment till his death on the Thursday following. Dr. Branson exhibited two microscopic drawings of the emphysematous lung, showing the ruptured air-cells.

Mr. Beckett exhibited the kidneys of a pig, a year old, one containing several cysts filled with pus and saline deposits, the largest about the size of a small walnut; the other kidney healthy.

RHEUMATISM; PERICARDITIS.

Dr. Branson exhibited the heart of a married man, aged 37, a gas-stoker in winter, and a painter in summer, who was admitted an in-patient of the Infirmary for acute rheumatism, on the 29th December last, and died on the 7th instant. He had suffered from acute rheumatism five or six years ago. The sounds of the heart were indistinct, while the impulse was preternaturally strong. The case presented nothing remarkable until four days before death, when the rheumatism left the extremities. The lungs were then found congested, there was great dyspnœa, and the patient ultimately died of asphyxia. The pericardium was adherent throughout, and the heart was hypertrophied, a condition in all probability resulting from the first attack of rheumatism. The lungs were in every part excessively congested, and there was some emphysema.

CIRRHOSIS OF THE LIVER.

Mr. Law exhibited the liver of a spring-knife cutter, aged 63. It was a good example of cirrhosis,—contracted, deformed, and of a yellow colour. He was admitted an in-patient of the Infirmary November 6th, and died on the 6th January, 1847. There was no icterus, but he had ascites, hæmaturia, and bloody discharges from the bowels. The urine was specific gravity 1.010, not coagulable. Kidneys healthy.

Mr. Law also exhibited the cervical vertebræ of a man, aged 45, a labourer. There was a fracture passing through the body and arch of the fifth. The injury was the result of a fall at the railway from some scaffolding, some earth also falling upon him. He died in about twenty-four hours.

ALLEGED POISONING BY SULPHURIC ACID.

Mr. Jackson detailed the particulars of a case of alleged suicidal poisoning by a girl aged 18, who stated that she had swallowed about four ounces by weight of concentrated sulphuric acid. She was proved to have procured that quantity at a druggist's shop, but there were none of the symptoms of her having swallowed any, so far as the state of the mouth, fauces, &c., &c., were concerned; in fact, the only symptom at all resembling any of those which result from the taking of this corrosive poison was pain at the region of the stomach. The only vomiting was what was excited by a large quantity of soap and water. From the history of the girl it appeared that she had threatened self-destruction on four other occasions, but had in every one proceeded only to a very slight extent, never seriously injuring herself; but what object she had in view, whether a morbid desire for notoriety or to obtain some point or other by frightening her mother, could not be ascertained. She had been twice confined in a Lunatic Asylum for a short period, and had suffered violently from epileptic fits, but not latterly. She was under treatment in the Infirmary, and on leaving there was again sent to an asylum.

Sixth Session.—Tenth Meeting, February 4, 1847.

The PRESIDENT in the Chair.

Mr. Hunter exhibited the cast of the arm of a mechanic, in which the veins were naturally exceedingly dilated.

STRANGULATED HERNIA.

Mr. Chesman detailed two cases of strangulated hernia. The first occurred in a female, aged 71, very much attenuated, who was seized with occasional vomiting on the 5th of March last. This continued until the 8th, when the vomiting became stercoraceous, and she then applied to Mr. Chesman. He found the abdomen swollen and tender; a tumour small and consolidated, so as to excite some doubt as to its being hernia, but the vomiting was conclusive. The taxis failed and on the following morning the operation was performed. A portion of omentum was found completely concealing, until lifted up, a small knuckle of intestine; both readily returned on the stricture being divided. In a short time after the operation, the patient expressed a great desire to evacuate the bowels, but nothing passed. In a few hours she became very much prostrated, and sank rapidly eighteen hours after the operation. On inspection *post-mortem* the ileum was found to be free. There was no effusion into the abdominal cavity. The bowel was contracted where the stricture had existed, so as hardly to allow the passage of a quill, and the inner coats appeared to have been absorbed, leaving nothing but the peritoneal coat, which latter, opposite to the wound, was perforated by a small round opening. There was great distension with fæculent matter above the stricture. The principal point for discussion Mr. Chesman considered to be the cause of this perforation; whether it had been produced by ulceration or by the probe point of the bistoury, or in the inspection *post-mortem*. In case it had been caused by the bistoury, how far would Key's director be of service in avoiding such an accident?

The other case occurred in a female servant, aged 35,

who, after suffering for some days from occasional vomiting, (she did not know how long,) applied to a medical man, who on examination found that the integument had sloughed, and there was oozing of fæculent matter. In a few days she was seen by Mr. Chesman, who found the parts much in the same state. After a confinement of several weeks, the external opening healed, and the woman recovered without having an artificial anus, and was enabled to go back to service.

The interest of this case was in the fact of strangulation going on to such an extent as to produce sloughing, without causing such symptoms as to require surgical aid before it had reached that point; and in the fact of the intestine having healed without leaving an artificial opening.

OPERATIONS UNDER THE INFLUENCE OF ÆTHER.

Mr. Thomas then detailed the particulars of three operations which he had that morning performed at the Infirmary, in which he had used the vapour of æther by means of an apparatus made by Messrs. Horne and Co., of Newgate-street, London.

The first was amputation of the leg above the knee of a boy, aged nine. The æther acted in two minutes, and the patient declared he had suffered no pain, and did not awake until all was over. The second was the removal of a portion of the upper jaw of a man, aged 38, the consequence of a malignant tumour. The æther operated in three or four minutes. He was not aware of the first incision, but soon became sensible, and was conscious of many things which passed, but did not give evidence of being in much suffering. The third was for harelip, in a girl aged 16, who was overpowered in three minutes, and stated that the first thing she was sensible of was the passing of the pins.

APPEAL TO THE MEDICAL PROFESSION THROUGHOUT THE KINGDOM ON THE "GENERAL MEDICAL ANNUITY FUND."

Gentlemen,—The project for establishing a "General Medical Annuity Fund," for disabled members of the profession, and for widows and orphans, has now been nearly two years before the public. It is true that in the first instance it was designed to form an integral part of the affairs of the "Provincial Medical and Surgical Association," but the meeting at Norwich having decided that it should stand alone, a separate and distinct Institution from that body, it now becomes necessary to reorganize it, and give its independent existence that permanence and stability which its value and importance demands.

The unexpected decision of the Norwich meeting somewhat staggered me, for I had previously felt I was acting under the auspices of the Provincial Association, and that many members of that important body had not only lent their powerful names to the Institution, but had aided its advancement by donations and subscriptions. Still, though I was staggered, I was not paralysed in my energies, nor disheartened as to the final accomplishment of the project, even though it stood alone; for that which possesses in itself an intrinsic virtue, seldom requires foreign aid to sustain it. The human heart, although corrupted by selfishness, and deadened by apathy, has many soft and gentle impulses, which need but the right stimulus to excite into activity, and when excited, a freshness and beauty is given to character, superior to renovated bodily vigour, after the wastings of disease; for "true philanthropy is health of soul."

Although the motives which have impelled me in all I have done in this matter are open to God, and I trust unimpeached by man, I have, nevertheless, felt a delicacy in obtruding myself,—an unwillingness to seem too prominent,—a desire that that which was of general interest to the profession, should find amongst its ranks others who would step forward and bear with me the heat and the toil. I thought if the project was worthy of support, the acknowledged talent of an enlightened profession like ours would be employed in its behalf, and expected, ere this, to have found many advocates; nor have I been altogether disappointed. Mr. Kelson, of Sevenoaks, Kent, has furnished to the *Provincial Journal* a letter, which evinces an enthusiasm worthy his benevolent spirit, and an activity in a pecuniary point of view, which is an unequivocal earnest of his sincerity. If every county in the kingdom would produce a spirit like his, the prosperity of the Institution could not be problematical. My thanks are likewise due to those gentlemen who honoured me with an answer to a circular, published a few weeks back. They have with much kindness encouraged my efforts,—expressed a confidence which is cheering, and, moreover, have promised active co-operation, so soon as they shall be put into a position to become active. This latter promise is more congenial and satisfactory to my mind than all the compliments they have been good enough to pay me, for I feel that counsel and help are essential. It is a gigantic establishment which is contemplated,—a vast Institution, comprehending in its grasp a huge tract of territory, and having for its object a diffusive spirit of benevolence. I therefore trust that many of these gentlemen will give to us their personal presence, at the forthcoming meeting at Northampton; it is worth while in such a cause to make some sacrifice. I am informed, both by the public press and by private letters, that the "General Medical Annuity Fund" has many well wishers, who are at present unknown as its supporters. These gentlemen are in abeyance, waiting the further development of the scheme, and its final establishment, ere they give to it their countenance and support. To such I would remark, "If you think well of the scheme, why hesitate to support it? Your help is most needed *now*, in the early stages of its establishment, when your opinions and your counsel might lead to valuable results. The growth of a tree depends upon the planting: if the labourers fail to loosen the earth, to arrange the fibres, to seek congenial soil and proper locality,—if they neglect to watch and water it, to shelter it from the rude blast, and sustain its

delicate and yielding form from the rough winds which blow upon it, the chances are that it perishes; but if, on the contrary, they combine their powers and unite their skill, in all that be necessary for its sustenance, then shall it take deep root in the earth, rear its majestic form, thicken its bole, and spread around its branches, while its impervious foliage shall shelter from heat and storm, and beneath which they may repose in calm security.

To advance the interests of medical science is a duty we all owe both to the public and ourselves. To watch over the political movements which bear upon our profession, more particularly at a time like the present, so rife with such movements, is equally important; but let not the claims of philanthropy and benevolence be lost in the struggle. Let their still small voice be heard; they speak to the heart, and it should feel it. In this age of general improvement, when the spirit of amelioration is abroad, and societies are established to meet the contingencies of disease and death, and the calamities which accompany such visitations; when the artisan, the mechanic, nay, the agricultural labourer, have combined to furnish help to their distressed brother, and to the bereaved families of their departed fellow-workmen;—can it be endured, that we, who claim for ourselves the advantages of education, the privilege of expanded minds, the influence of moral and religious feelings, and in some measure the pride of clanship—can it be endured, that in pure benevolence and nobleness of spirit, we should be outdone by these? Does the cause of the widow and orphan require either eloquence or talent to plead with enlightened men? Is not the certainty of their fallen condition, when shrouded with poverty and neglect,—oftentimes their utter helplessness, their agony, their privations, eloquence itself? Cannot imagination picture how forlorn and miserable must be that object who, having once enjoyed ease, comfort, and competency, is, from no fault of her own, but from the dispensations of Heaven, thrust from her home and her pleasures to toil for bread, to sink into dependence, or to have her weekly dole from the hands of a parish functionary? It is rank hypocrisy to put a prayer to Almighty God in the venerable ritual of our church, asking *Him* "to defend the fatherless children and widows," while we refuse a small mite from our resources to make the prayer effectual, as far as human means can make it.

The difficulties under which many worthy and intelligent practitioners labour in a pecuniary point of view, render assurance upon their lives often impossible, but admit that a prudent and careful man has paid from his yearly income sufficient to guarantee to his widow a thousand pounds. Now, what is the interest she will receive from this amount? Unless she adopts some speculative mode of investment, (which is always dangerous,) or to obtain large interest, gets security, uncertain as to punctuality of payment, her income from the ordinary funds of the country will scarcely afford a very humble maintenance for herself; but if she have a family, it is obvious she must herself labour to obtain any respectable position, and it may be she is utterly unqualified for such labour. The capital must not be touched, for that capital is designed for ulterior purposes, to place her children in suitable situations, and to enable them in the end to embark in business on their own account. Now, to meet such cases, is the great object and design of the directors of the "General Medical Annuity Fund." An annuity, accruing from such a co-operative institution, would place the widow in a position of comparative independence; but when the average calculation of mortality amongst medical men, as proved by statistical returns, is compared with other professions, the lowest on the scale, the inference is fair that many die before they can have had time to make provision of any kind.

Take the following fact as an example:—"A young physician, respected for his general demeanour, and honoured for his talents, possessing public appointments, with every prospect of obtaining extensive practice, died after a short illness, (a few minutes only,) at the early age of 36, leaving a widow and five children TOTALLY unprovided for." I quote this passage from my esteemed correspondent, to show that I have not drawn my pictures from imagination, but trusted the detail of facts.

The proposition for a "General Medical Annuity Fund" has occupied the consideration of wiser heads than mine. Dr. Percival, in his "Medical Ethics," more than forty years ago, threw out the suggestion, but no one appeared to act upon it. I have quoted the passage in former communications to medical periodicals, but it will bear reiteration. "In the county of Norfolk, and in the city of London, benevolent institutions have been lately formed for providing funds to relieve the widows and children of apothecaries, and occasionally also members of the profession who become indigent. Such schemes merit the sanction and encouragement of every liberal physician and surgeon, and were they extended, their usefulness would be greatly increased, and their permanency almost with certainty secured. Medical subscribers from every part of Great Britain should be admitted, if they offer satisfactory testimonials of their qualifications. One comprehensive establishment seems to be more eligible than many on a smaller scale, for it would be conducted with superior dignity, regularity, and efficiency;—with fewer obstacles from interest, prejudice, or rivalship;—with considerable saving in the aggregate of time, trouble, and expense;—with more accuracy in the calculations relative to its fund;—and, consequently, with the utmost practicable extension of its dividends."*

Some gentlemen have thought a guinea a year subscription would be inadequate to accomplish the object we design. It is scarcely necessary to enter again into this question, for I have met it on many occasions. A guinea a year subscription *will* enable us to fulfil the engagements to which we pledged ourselves;† and should the Institution meet with the patronage it deserves, it *will do much more*, because the liberal and the kind-hearted of the profession will not confine themselves in their philanthropy—we have already

* "Medical Ethics," p. 359. Edition 1827.

† See "Address," &c., published by Churchill, p. 9.

had examples of this fact—nor will the public, when it is properly represented to them, withhold their assistance in furthering so exemplary an object. If our anticipations in these particulars be realized, we may fairly hold out the prospect of better annuities.

It has been stated too, publicly, that there is an objection in sending money to Northampton, and that making application for annuities there, would be inconvenient; but what is the consequence of locality to a "General Medical Annuity Fund," provided the parties who controlled it are men of integrity and honour, and provided the representative system was fully carried out? It will be our great aim to neutralize all objections of this nature. When the project was first mooted, it was done at the annual meeting of the Provincial Association, held at Sheffield; it was received there without a dissenting voice, and a committee for carrying out the scheme was appointed upon the spot. The retiring president of that Association, Dr. Robertson, of Northampton, kindly accepted the office of treasurer, while the directors were all gentlemen chosen for their high standing in the profession, and their known integrity. For my own part, I took the office of Honorary Managing Director, only as an earnest of my zeal, devoting to the cause my time, and the small measure of ability I might possess, being, in short, willing to "spend and be spent" in the noble undertaking. But the institution is now a citizen of the empire, and is ready to take up its abode where it has the best chance of support. I am willing at any moment to yield the feeble protection I have given it to any more efficient guardianship; nor do I believe an objection would be raised by my colleagues to placing it in a position of greater advantage than we may possess. Our object is the final establishment of the "Fund," and we care not who are the parties who shall develop its energies, and spread abroad its usefulness.

The medical profession throughout the kingdom are especially invited to the consideration of this subject. Honorary local secretaries are required in the different counties and districts for furthering the scheme, and we shall esteem it an especial favour if gentlemen will accept the office voluntarily,—that is, will offer their services, rather than wait for an application. Oh! let them remember the greatness of the cause, and the glory of its achievement, and methinks they will not lack in their zeal.

In the early part of the spring, a meeting of the subscribers will be held at Northampton, of which due notice will be given by advertisement in this Journal. In these times of rapid travelling, when railway communication puts distance at defiance, we earnestly hope that many gentlemen will sacrifice to us their time and services on this interesting occasion. A noble superstructure is about to be raised, the foundations of which are love, in its best and purest acceptation, while its hallowed cement is co-operative philanthropy, upon which the blessing of God shall rest, for God will not withhold his blessing, when men "Hear the cry of the orphan, and wipe tears from the widow's eyes."

Gentlemen who are desirous to be present at this meeting, will confer a favour if they will apprize either Dr. Robertson or myself of their intention.

I have the honour to be, Gentlemen,
Your obedient servant,
EDWARD DANIELL,
Newport Pagnell, Bucks, Managing Director.
March 1, 1847.

REMARKS ON THE CASE OF ÆTHER-INHALATION AT THE ESSEX AND COLCHESTER HOSPITAL.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I enclose a few remarks on the late case of lithotomy at our Hospital, as it seems to me that the statement of the case has produced an impression that the immediate cause of death was apoplexy or compression of the brain.

As the æther was exhibited by me, and as I was particularly observant of its effects, and being of opinion the symptoms that attended the inhaling do not bear out such impression, and that the *post-mortem* appearances do not establish Mr. Beckingsale's inference, that "compression of the brain" resulted, I request your insertion of the accompanying observations, and am,

Sir, faithfully yours,
EDWARD WILLIAMS, M.D.
Senior Physician to the Essex and Colchester Hospital.

The æther was inhaled, mixed with a free current of atmospheric air; the mouth-piece of the apparatus, Weiss's, did not completely cover the mouth so as altogether to preclude the external atmosphere; hence the inhaling process was the longer in producing insensibility.

In no stage of the inhaling process was there lividity of countenance so marked as to excite apprehension of cerebral pressure; the aspect was rather characteristic of one in a state of syncope; the pupils were not dilated, and the stertorous breathing was considered by me at the time to proceed from relaxation of the uvula, and from the nostrils being compressed so as to prevent inspiring through them. This view was corroborated by the fact, that on removing the pressure from the nostrils, and on suspending, for a short period, the inhaling process, the stertor or snoring then ceased.

Before the patient was removed from the operating table consciousness returned, and he answered questions put to him relative to his feelings; neither was there observable paralysis, or other symptom of cerebral pressure, from the period of the operation till his death, being sensible to the last.

At the consultation of the Medical Staff, the singularly indistinct action of the heart was remarked. This, with the general prostration, decided us in recommending stimuli and a turpentine injection.

After death the heart was, comparatively speaking,

empty, but the lungs were engorged, the blood being dark and fluid.

That such a state of blood was unnatural, nor an attendant of death from lithotomy, is an admission we feel bound to allow; and when a similar state of that fluid has been found on death after inhaling æther, we deem that the probability amounts almost to a certainty, that the æther was the cause of this fluid state of the blood. Yet we must also observe, that the absence of those symptoms that ordinarily accompany cerebral pressure, the indistinct movements of the heart, and the engorged or loaded state of the lungs, point to the state of the latter organs as the immediate cause of death. But whether this passive congestion is to be attributed to the changed state of the blood, or whether continued insensibility may give rise to local engorgement, remains yet to be determined.

Your correspondent, Mr. Beckingsale, suggests depleting, when *an apoplectic tendency presents itself*. Such recommendation would be judiciously adopted were cerebral pressure observable; but as I argue that such a state of brain, with its accompanying symptoms, did not exist, consequently depletion was not applicable. Still the question arises as to the proper course to be hereafter pursued under a like train of circumstances—namely, with a perverted state of the blood, and with local passive congestion. I apprehend that in transfusion we possess a means of replacing the blood when so depreciated in vitality as to be injurious to the organs through which it circulates, and local congestion must be treated according to the requirements of the case.

Finally, Mr. Editor, we should feel obliged by seeing reported a few of those unsuccessful cases, which have occurred at the Metropolitan Hospitals, as it is only by the accumulation of numerous and carefully observed facts that we may be expected to deduce correct general principles of treatment.

Colchester, March 27, 1847.

APPARATUS FOR THE INHALATION OF ÆTHER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I beg to send you the accompanying diagram of the section of a stop-cock, intended to be used in any apparatus for inhaling æther, by means of which the supply of æther can at once be cut off, and the patient allowed to breathe the pure air, without removing the "clip" from the nose, or the apparatus from the mouth, which it is often inconvenient to do. On the approach of sensibility, the stop-cock merely requires to be turned back, when the patient will again breathe the æther.

Fig. 1 represents the stop-cock arranged for inhaling the æther, and on turning it in the direction of the *large* arrow, it assumes the position of Fig. 2, allowing the patient to breathe the pure air.

I am, Sir,
Your obedient servant,
PROCTER WRIGHT.

Norwich, March, 1847.

Fig. I.

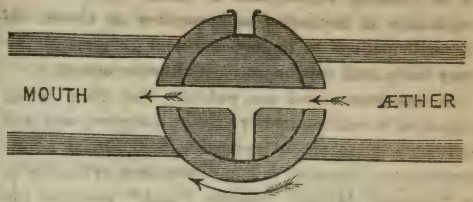

Fig. II.

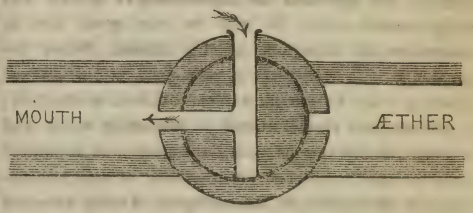

P.S. I would beg to suggest that if the nose be plugged with some lint, it will be found equally efficacious and much more comfortable to the patient, than closing it with either the "clip" or the fingers. I would also recommend, that the patient should make himself acquainted with the mechanism of inhaling, by practising it before he is brought on the table for an operation, and that the mouth-piece should be made of either horn, wood, ivory, or metal, of the form of a cup, and be just big enough to cover the lips, without interfering with their motion, as this shape will be found more convenient than the large leather pad that is supplied with Robinson's apparatus.

AMPUTATION UNDER THE INFLUENCE OF ÆTHER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

On Thursday, February 25th, I amputated the leg of George Shaw, of Royal George Mills, below the knee. He had been suffering from scrofulous disease of the ankle-joint for some years. On the Tuesday before I made him inhale æther. He was some time before he could understand the method of breathing it; however, he was at last completely under its influence and perfectly unconscious, and remained in that state a few minutes. He was so pleased with it that he asked for "another pipe." On Thursday, in the presence of Mr. W. F. Tuckett, Messrs Blackbury and Barray, surgeons; H. Mackworth, Esq., C. E;. J. H. Whitehead, Esq., and many other gentlemen, he again inhaled the æther and was completely unconscious in less than a minute. I removed the leg four inches below the knee, by the double circular incision; he did not lose one ounce of blood, three arteries were tied, and he was sensible in a few minutes. The stump was allowed to become glazed; the edges were then brought together with one suture and plaster. He was put to bed, he had a little weak brandy and water given him, and an opiate at bed time. On the twelfth day the first ligature came away, and the remainder on

the fifteenth; he has been out daily since, the stump is quite healed, and he yesterday walked with a crutch and stick to my house, a distance of two miles and a half. He states he did not feel anything of the operation, and that his sensations were more agreeable than otherwise.

I am, Sir,
Yours faithfully,
H. H. BROUGHTON.

Dobcross, March 19, 1847.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

NATURE AND SOURCE OF THE CONTENTS OF THE FŒTAL STOMACH.

The source of the nutritious matter which is found in the alimentary canal of the fœtus, is a problem which has never been satisfactorily solved. Harvey looked upon it as derived from the liquor amnii swallowed by the young animal. Geoffrey St. Hilaire having found the same substance in fœtuses with an imperforate œsophagus, very naturally concludes that such cannot be its source. Dr. Robert Lee, who is the latest writer upon the subject, regards the liver as the source, the function of that gland being not only to separate an excrementitious substance, but also to supply an albuminous secretion to the intestines, through the hepatic duct. Dr. Robinson, who has recently investigated the nature and origin of the fœtal intestinal contents, comes to the following conclusions:—

1. That the stomach of the fœtus, during the latter part of its uterine existence, invariably contains a peculiar substance, differing from the liquor amnii, and generally of a nutritious nature.

2. That in its physical and chemical qualities, it varies very much in different animals, being in no two species precisely similar.

3. That in each fœtal animal, the contents of the stomach vary much at different periods; in the earlier stages of its development, consisting chiefly of liquor amnii, to which the other peculiar matters are added gradually.

4. That the liquor amnii continues to be swallowed by the fœtus up to the time of birth; and consequently after the formation of those matters, and their appearance in the stomach.

5. That the mixture of this more solid and nutritious substance with the liquor amnii constitutes the material which is submitted to the process of chymification in the fœtal intestines.

There is, however, no explanation here of the source of the solid matters above spoken of, and Dr. Robinson subsequently states his belief that they are not secreted by the stomach itself, nor by the liver, as affirmed by Dr. Lee; but he thinks it probable that they are the product of the *salivary glands*.—*Monthly Journal of Medical Science*, Febr., 1847.

EXHALATION OF BICARBONATE OF AMMONIA IN RESPIRATION.

Mr. Thomson recommends the following plan for demonstrating the presence of ammonia in the breath:—Air which had passed through dilute sulphuric acid was respired; it was then expired through a tube surrounded with water at 32°, to the farther end of which a vessel was attached to receive the fluid which was condensed. This was acidulated with muriatic acid, evaporated to dryness, and the residue dissolved in a few drops of water. On adding a strong solution of potash to this solution, ammonia was evolved, as evinced by its odour. Mr. Thomson calculates that rather more than three grains of solid bicarbonate of ammonia are exhaled daily by an adult, and thus the quantity furnished annually by London amounts to 150 tons. In this way animals supply ammonia for the support of the vegetable kingdom.—*Medical Gazette*, February 12, 1847.

[The editor of the *Medical Gazette* in remarking upon these experiments thinks that there is a source of fallacy not noted by Mr. Thompson,—viz., the animal matter which is exhaled. This when collected in sufficient quantities would yield ammonia. In order to remove the doubt, he suggests that it should be determined whether yellow arsenite of silver is precipitated on passing the condensed vapour into mixed solutions of arsenious acid and nitrate of silver.]

PRACTICAL MEDICINE.

EXPERIMENTS ON THE COMPARATIVE ACTION OF MEDICINES EXHIBITED BY THE STOMACH AND BY THE RECTUM.

MM. Restelli and Gaetano Strambio have instituted a series of experiments to determine this point, which is not without considerable interest in a therapeutical point of view. The medicines used were strychnine and morphine. A poisonous dose of the former produced in the dog its characteristic effects in twenty-eight minutes when injected into the stomach; in nineteen minutes when thrown into the rectum. The salts of morphine exhibited the same differences. Thus the poisonous symptoms appeared, when given by the stomach, in five minutes and ten seconds; by the rectum in four minutes and sixteen seconds.—*Gazette Médicale*, Fevr. 15, 1847.

[From these results, which were ascertained to be constant in a large number of experiments, it appears that certain medicinal substances act more energetically by the rectum than when given by the mouth; but it must not be supposed that this will be observed in all classes of medicines, as many purgatives for instance are well known to be much less efficacious given by the bowels than by the mouth. As regards the preparations of opium, we may state that we have often procured sleep under critical circumstances, by a dose thrown into the rectum, when repeated exhibitions of the same dose by the mouth had failed to subdue restlessness.]

NEW REMEDY IN PERTUSSIS.

A physician of Ghent has called attention to the Narcissus Pseudo-narcissus in hooping cough. The flower is the part used, which is dried and powdered; the dose thirty grains twice a day.

A surgeon of the same town announces very

satisfactory results from the employment of the mistleto in the same disease.—*Medical Times*, February 20th.

COD-LIVER OIL AS AN EXTERNAL APPLICATION IN OPHTHALMIA TARSI.

Mr. Cossar, of Darlington, in a letter to the Editor of the *Lancet*, states that he has found cod-liver oil beneficial as an external application in the ophthalmia tarsi of scrofulous subjects, having used it in a number of cases with complete success. The oil is to be rubbed on the eyelids three times a day.—*Lancet*, Feb. 27th.

ON THE THERAPEUTIC VALUE OF THE PREPARATIONS OF IODINE IN SYPHILIS.

M. Aran terminates a long memoir on this subject with the following conclusions:—

1. Multiplied experiments establish incontestably that the preparations of iodine possess valuable properties in the treatment of syphilitic diseases.

2. The iodide of potassium is to be preferred to all other preparations.

3. The iodide of potassium is not to be given indiscriminately at all periods of the disease; it is more particularly applicable to what has been termed by Wallace the pustular form of syphilis; it is also specific in the tertiary forms. Its powers in the primary disease are not so well marked.

4. It is, particularly in cases in which mercurial medication fails, or when the syphilitic symptoms are of long standing, that the iodide of potassium should be substituted for the preparations of mercury. Under these circumstances this medicine supplies a want which was long felt by the profession, and which was of most injurious consequences to the patient.

5. It is doubtful whether it is advisable to combine the iodine and mercurial treatment.

6. The inconveniences which sometimes follow the use of the preparations of iodine should not cause us to abandon it, as they may be obviated by its cautious administration.—*Archives Générales*, Janvier, 1847.

SURGERY.

ON THE APPLICATION OF ICE IN THE TREATMENT OF INJURIES.

The application of ice, to a great proportion of severe wounds, is the established practice of several of the most distinguished French surgeons.

In the Hôpital St. Louis, burns are treated in this way, and its application in extensive burns appears to us to be that in which its employment is most strongly opposed to our treatment of the same injuries. "However extensive the surface or the depth of a burn, it is immediately covered with bladders half full of pounded ice, which are fixed by different contrivances, according to the situation of the injured part, and this treatment is continued till the separation of the eschars. If the burn be very extensive, the patient, placed in a sheet held by two men, is plunged into a cold bath."—*Annales de Therapeutique*, Mai, 1846.

Upon this the Editor of the *Edinburgh Monthly Journal* remarks, that it is said that the patient experiences immense relief from this treatment, and that he is comparatively free from pain as long as the body can bear the extreme cold. The bath is repeated frequently. It is believed by the advocates of this treatment that the extent of sloughing of the surface is thus greatly diminished; in other words, that the extent of destruction of the injured parts does not depend on the severity of the original burn, but on the intensity of the reaction which occurs afterwards, and the beneficial operation of the cold, is attributed to its preventing, or in a great measure subduing, this re-action.

However rational the theory, we believe that in practice this treatment of very extensive burns will invariably be found inapplicable. The surface of the body in these cases is in the first place cold, and the patient collapsed and pulseless, and we do not think the most strenuous advocate of the ice and cold-water system would immerse a patient in this state in a cold bath. On the contrary, stimulants must be administered, and the small quantity of caloric remaining in the body is to be preserved by the external application of cotton wadding, and other non-conducting substances. It must be remembered, too, that the shock from an extensive burn is not recovered from so rapidly as that occasioned by most other injuries, and frequently soon after the full establishment of re-action, the separation of the sloughs has commenced, the extent of which we believe to depend entirely on the severity of the original burn, and not on the treatment employed. The application of ice in smaller burns we should think much more worthy of trial; indeed we are aware that great relief is sometimes obtained from its use, and as relief from pain in such cases is one of the best indices of its treatment, the feelings of the patient may very properly guide us in its employment.

In the Val de Grace, M. Baudens uses ice extensively in the cases of wounds, contusions, and compound fractures, and apparently with much success; but this surgeon, not content with the degree of cold produced by the ice, reduces the temperature to a much lower degree (15° below zero C.,) by mixing it with common salt. It is allowed, however, that this extreme degree of cold frequently produces considerable pain to the patient, and a feeling of tightness and congestion in the part; and we should naturally expect such an extreme degree of temperature to prove rather a source of irritation to the part than to act in the beneficial way in which it is represented. By using cold water, and renewing its application very frequently, we probably obtain as low a temperature as it is advisable to apply on most occasions.

We feel assured that the indiscriminate and continued application of ice to wounds and injuries is frequently productive of mischief. We have witnessed fatal erysipelas on several occasions supervene during its application; and in a large hospital in the north of Germany, where this treatment was indiscriminately applied in every case of wound, contusion, and fracture, simple or compound, fatal cases of phlebitis and erysipelas occurred with greater frequency than we have ever seen elsewhere.—*Monthly Journal of Medical Science*, January 1, 1847.

TREATMENT OF PROLAPSUS ANI.

Dr. Hake has made public a plan of treating this occasionally very troublesome accident, which was

suggested to him by a friend who had invented it as a remedy for his own sufferings.

The plan simply consists in returning the bowel, and placing against it a piece of sponge four or five inches long, an inch wide and half an inch thick, rolled upon itself so as to form a pad. The buttocks are then brought as nearly as possible into apposition, and retained in that situation by straps of plaster passed lengthways from one to the other. By this means a very effectual support is afforded to the relaxed bowel. If there is much irritation about the anus the part should be washed with vinegar and water.—*Medical Gazette*, February, 1847.

[We regard this simple contrivance, the effects of which are stated by Dr. Hake to have been equally satisfactory in other cases witnessed by himself, as one of great value, and likely to supersede many more expensive inventions. The benefit derived from it might probably be increased by dipping the sponge previous to application in some astringent solution, as a decoction of rhatany root, or a weak solution of nitrate of silver.]

ON FISSURES AND EXCORIATIONS OF THE NIPPLE.

M. Donné *(Conseils aux Meres sur l'Allaitement)* observes that fissures of the nipple, so frequently observed in nurses, are not to be deemed solely as an inconvenience unconnected with the secretion and qualities of the milk; they have other inconveniences beyond the mere pain which they produce. He does not doubt that they are always related to a defective condition of the lacteal secretions, not less injurious to the infant than to the nurse, and in this point of view he considers them worthy of every attention. He states that he has constantly found that women who are subject to these fissures have a poor quality of milk, and that it is commonly mixed with mucosities. So constant is this connection, that he considers the fissures the indication, if not the consequences, of poverty of the milk, of its being deficient in quantity, and of its difficulty in flowing,—which difficulty causes the infant to make violent and injurious efforts on suction. It happens too, that the infant becomes ill-nourished, and this, according to Donné, causes the secretion of an acid saliva, which adds to the mischief.

[In opposition to this theory of mechanical violence as a cause of sore nipples, it may be observed, that Dr. Rossi has noticed that the painful excoriation never appears, even in retracted nipple, where the greatest efforts on the part of the child are required, unless the infant's mouth presents aphthous ulcerations. He states that he has proved this to be the real cause, by applying children so affected to the bosom of healthy women, when fissures of the nipple have been the result.—*Ranking's Abstract*, vol. ii., p. 294.]

MATERIA MEDICA.

ON THE PREPARATIONS OF IRON.

Dr. Clarke *(Dublin Medical Press*, Jan. 27th,) has published a communication, in which he gives a formula for producing a better preparation of carbonate of iron than has hitherto been adopted. The most active preparations of iron have been determined by chemists to be those which contain the metal in the state of protoxide; but it has always been found difficult to preserve the metal in that form from its great affinity for oxygen. Even in the saccharine carbonate of the Edinburgh Pharmacopœia this change takes place, and thus prevents the full advantage which had been anticipated by the proposers of that formula. Dr. Clarke observes that the specimens examined by him rarely contained more than from fifty to sixty per cent. of real carbonate of the protoxide, and he therefore has endeavoured to improve upon the process, by uniting the precipitate as soon as it is formed, with as much sugar as it is capable of combining with. The details are as follows:—

He first makes a solution of five ounces of carbonate of soda in twenty-four ounces of water, and adds to it four ounces of simple syrup; and having previously obtained a pure sulphate of iron, by sulphuric acid and water with iron wire, he then dissolves four ounces of it in two pints of cold water, and instantly adds the solution of soda and sugar. The process being conducted, as in the Edinburgh formula, the whole is thrown on a filter, and the precipitate rapidly mixed with two ounces of sugar, and dried by exposure to air. Dr. Clarke thus gets a preparation containing from ninety to ninety-five per cent. pure carbonate of iron.

TOXICOLOGY.

ON THE TREATMENT OF POISONING BY ACIDS.

In poisoning by acids, the antidotal treatment alone suffices, if applied early. All toxicological writers advise the employment of magnesia, the alcaline carbonates, and soap, but these are not, according to M. Bouchardat, sufficient, and he thinks therefore, that he is entitled to some credit as having laid down a more definite treatment.

It is well to commence, he observes, with calcined magnesia in excess, but as a portion of the acid is absorbed, and tends to destroy life by producing coagulation of the blood, it is not enough to have neutralized the acid in the stomach, but some soluble antacid must be given, which may be absorbed, and so neutralize the acid which has reached the blood. The best substance to effect that purpose is the bicarbonate of soda. The author remarks, that it is of importance not to exhibit the soda in the first instance, as the disengagement of the carbonic acid may cause rupture of the coats of the stomach.

TREATMENT OF ARSENICAL POISONING.

M. Bussy has demonstrated that magnesia forms an insoluble compound with arsenious acid and may therefore be employed as an antidote to that poison. The treatment recommended by Bouchardat is the following:—

After having produced vomiting, give the hydrated peroxide of iron in excess, in combination with magnesia. If there be prostration of the vital powers, the surface is to be stimulated by sinapisms, frictions, warmth, &c. Finally, the expulsion of the poison is to be facilitated by purgatives and diuretics.

TREATMENT OF POISOING BY LEAD.

There are three circumstances to be considered in lead poisoning:—

1. The treatment of poisoning by the salts of lead in large doses.

2. The treatment of slow poisoning by the salts of lead.

3. The prophylactic treatment.

The antidote most relied upon by Bouchardat for the fulfilment of the first indication is the hydrated persulphuret of iron given in excess, mixed with syrup. Vomiting and purging may be solicited by large doses of croton oil. [The second and third indications are not touched upon.]

TREATMENT OF POISONING BY OPIUM AND ITS PREPARATIONS.

1. Empty the stomach by emetics or the stomach-pump.

2. Give a solution of the iodide of potassium.

3. Give strong coffee, without sugar. The proportions recommended by Bouchardat are, an ounce and a half of coffee to half a pint of water, to which is added brandy, half an ounce.—*Annuaire de Therapeutique* 1847.

POISONING BY ARSENIC, DATING BACK TEN YEARS: DETECTION OF ARSENIC IN THE BONES OF THE SKELETON.

A case of poisoning occurred in the village of Scamagne, without the fact having reached the ears of justice. Ten years after, certain circumstances arose which led to the apprehension of four suspected persons. A medical enquiry was instituted, and a skeleton was discovered, which was recognized as belonging to the murdered individual, and who, upon the confession of one of the parties implicated, had died at the end of twenty-four hours, after having taken a large quantity of arsenic. The skeleton and the remains of the funereal appurtenances were submitted to chemical analysis, and arsenic was discovered to exist in repeated instances. The source of the poison was rendered more certain by the fact, that none was discovered in a skeleton which lay so close to the above, that it was at first mistaken for it.—*Cours d' Assize de la Haute-Vienne.—Gazette Méd.*, Janv., 1847.

ANECDOTES OF THE MEDICAL PROFESSION.

[The following anecdotes of the Medical Profession are the "gleanings" of an esteemed member of the Provincial Association. They afford a tribute to the skill, humanity, and disinterestedness which characterize the genuine medical practitioner, and are here recorded as an example and encouragement to others to go and do likewise.]

1.—The anecdote most flattering to the medical profession, which I would recall to your remembrance is, the occasion of the first establishment of the East India Company's power on the coast of Coromandel, which was procured by the favour of the Great Mogul to one of our profession, Gabriel Boughton, of the ship *Hopeful*, in gratitude for his efficient help in a case of great distress to the monarch. It seems that in the year 1636, (!)* (a very early period of our direct intercourse with India, after the Portuguese had discovered the passage thither by the Cape of Good Hope,) one of the princesses of the Great Mogul's family had been burnt dreadfully by accident, and that a messenger was sent to Surat, where foreign traders resorted, to desire the assistance of one of the English surgeons there, for they had acquired a great reputation amongst the natives for their skill in the cure of diseases. Gabriel Boughton proceeded forthwith to Delhi, and was successful in performing a cure on which the Great Mogul's minister asked him what, his master could do for him to manifest his gratitude for so important a service? Gabriel answered with a disinterestedness,—a generosity,—a patriotism beyond any praise, "Let my nation trade with yours." "Be it so." A portion of the coast was marked out for the future resort of English ships, and all duties were compromised for a small sum of money.† A better station, it is true, was selected at the mouth of the Hooghly river some twenty years afterwards, and Calcutta was built; but *here* was the first establishment of our power. Here did the civilization of that vast continent begin; from hence the blessed light of the Gospel may have been first promulgated amongst a hundred millions of native idolaters, since subjected to the control of British power, and made partakers of our enlightened comforts."—*Sir Henry Halford "On some results of successful practice of Physic."*

2.—It has been before remarked how the English were indebted in 1655, to the skill of an English Doctor for permission to settle at Pipley; in 1713 our country was again indebted to its medical skill for further privileges. Mr. Hamilton, a surgeon in the East India Company's service, having accompanied an embassy to Delhi, soliciting certain privileges, a powerful opposition was met in the Mogul's court, and the embassy were on the point of returning unsuccessful, when it so happened that the Emperor Ferokshere was seized with a dangerous illness, which baffled the skill of the native physicians. Mr. Hamilton's advice was solicited, given, and successful. On being desired to name his reward, he nobly cast aside private advantages, and implored a grant of the objects of the mission, which were gratefully conceded. Hamilton's remains rest without a stone to mark the spot in the burial-ground at Calcutta, his patriotism and his services alike unremembered; and although the natives of India have been more linked to England in ties of personal affection, by means of the skill of our surgeons and physicians, than by any other class of the East India Company's servants, they are the worst paid and

* In 1656 (?) owing to the skill of an English doctor, (Boughton,) the East India Company received the Mogul's sanction to establish a factory on the right bank of the river Hooghly.—*Montgomery Martin's History of the British Colonies*, vol. i., p. 4.

† "On the payment of three thousand rupees, a government license for an unlimited trade, without payment of customs, in the richest province of India, was recorded,"—*Mill's British India*, vol. i., p. 7[illegible].

most ill-requited officers in the East; their lives are spent in doing good, and old age brings with it little to solace but the remembrance of the past. It is to be hoped that a profession, combining in its exercise, science, extensive knowledge, and christian charity, will soon meet its deserts.—*Montgomery Martin's History of the British Colonies*, vol. 1, p. 87.

[There appears considerable discrepancy in the dates. Sir H. Halford says that Gabriel Boughton obtained his permission in 1636—*i. e.*, four years after the Great Mogul granted permission to establish a factory at Pipley; and Mr. Martin says, that in 1656, owing to Boughton's skill, permission was given to establish one on the right bank of the Hooghly, and in alluding to this he also says it was in 1655. The discrepancy, however, does not alter the merit of facts so creditable to our profession.]

3.—"I was very anxious to procure, if possible, some medical advice for Mysseri, whose illness prevented my departure. Every one of the European practising doctors, of whom there had been many, had either died or fled; it was said, however, that there was an Englishman in the medical service of the Pasha, who quietly remained at his post, but that he never engaged in private practice. I determined to try if I could obtain assistance in this quarter. I did not venture at first, and at such a time as this, to ask him to visit a servant who was prostrate on the bed of sickness, but thinking I might thus gain an opportunity of persuading him to attend Mysseri, I wrote a note mentioning my own affair of the sore throat, and asking for the benefit of his medical advice. He instantly followed back my messenger, and was at once shown up into my room. I entreated him to stand off, telling him fairly how deeply I was "compromised," and especially by my contact with a person actually ill, and since dead of plague. The generous fellow with a good humoured laugh at the terrors of the contagionists, marched straight up to me and forcibly seized my hand, and shook it with manly violence. I felt grateful indeed, and swelled with fresh pride of race, because that my countryman could carry himself so nobly. He soon cured Mysseri as well as me, and all this he did from no other motives than the pleasure of doing a kindness, and the delight of braving a danger."—*Cairo and the Plague. Eōthen*, p. 314.

(To be continued.)

Medical Intelligence.

HEALTH OF TOWNS.

Lord Morpeth obtained leave on Tuesday, March 30th, pursuant to notice, to bring into the House of Commons a Bill for improving the Health of Towns.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, March 11th:—John Shepherd Fletcher, Manchester; Thomas Oldacres, Market Bosworth; Thomas Binford Eyre, Yeovil; Nathaniel Best Gill, E. I. Comp. Service; George Booker, Dronfield, Derbyshire; Edward Mawthill Tearne, Stockton, Worcestershire; Horatio Lillifant, Exeter; Charles Henry Holman, Crediton; Edward Hancock, Stoke, near Plymouth.

Gentlemen admitted Licentiates, Thursday, March 18th:—Robert Finch, Greenwich; Robert Kemp Buckell, Southampton; George Anstice Knott, Bristol; John Edmund Currey, Essex.

OBITUARY.

Died, February 27th, at Tripoli, John Dickson, Esq., M.D., Surgeon, on the half-pay of the British Navy. Dr. Dickson had been resident at Tripoli upwards of thirty years, and such had been the extent of his gratuitous attendance on the indigent, that his decease was looked upon as a great public calamity. His funeral was escorted by a military guard of honour, sent by the Pacha, and attended by the Foreign Consuls, by all the European residents of every class, and by several thousands of Jews and Mahomedans.

March 16th, at Southampton, aged 28, Julius Veronge, Esq., M.D., Surgeon of one of the Royal West India Mail Packets.

March 20th, aged 71, Charles Rochement Aikin, Esq., of Bloomsbury Square, a Member of the Royal College of Surgeons, and well known for his scientific and practical knowledge of chemistry.

March 26th, in Bedford Square, T. Wilkinson King, Esq., Surgeon, Lecturer on Pathological Anatomy, &c., at Guy's Hospital.

BOOKS RECEIVED.

The Microscopic Anatomy of the Human Body in Health and Disease. By Arthur Hill Hassall, F.L.S. &c. Part VIII. London: Highley. 1847.

Lecture, introductory to a Course of Clinical Medicine, delivered in the Theatre of Queen's College, Birmingham. By Samuel Wright, M.D., Edin., F.R.S.S.A., Physician to the Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham, &c. &c. London: Churchill. 1847. 8vo., pp. 23.

An Essay on the Nature and Properties of the Tenbury Mineral Waters. By A. W. Davis, M.D., London: Whitaker. 1847. pp. 40.

CONICAL CORNEA.

Mr. W. White Cooper would feel greatly obliged to any gentleman who would, from observation, favour him with the particulars of cases of *conical cornea*, together with an abstract of the treatment employed, and the result.

2, Tenterden Street, Hanover Street.

TO CORRESPONDENTS.

Communications have been received from Mr. F. Buckill; the Sheffield Medical Society; Dr. J. Campbell; the Birmingham Pathological Society; Mr. Bartrum; Mr. J. E. Wood.

MEDICAL & SURGICAL JOURNAL.

A COURSE OF LECTURES ON CLINICAL MEDICINE.

By W. R. Basham, M.D., Physician to the Westminster Hospital.

Lecture IX.

Clinical remarks on idiopathic Phlebitis: Record of the case; treatment and convalescence; probable cause of the disease; reasons for thinking it connected with the rheumatic diathesis.—Pathological conditions of the vein in phlebitis: exudation of plastic lymph; tendency of venous inflammation to centripetal progress.—Changes occurring in the plastic deposit:—I. Solution and removal.—II. Semi-organization and persistent thickening.—III. Purulent transformation and its serious consequences.—Observations on the treatment.—Cold and rheumatism considered as predisposing causes of phlebitis.

Gentlemen,—Cases of idiopathic phlebitis—inflammation of the veins occurring spontaneously—are of sufficiently rare occurrence to be of some interest to you in a course of clinical instruction. On this occasion I propose to point out to you the pathological conditions of this disease, the most frequent predisposing causes, the general principles of treatment, together with the ulterior consequences or effects of this affection, when existing independently of local injury. The case of inflammation of the saphena veins of both legs in a man in Burdett ward will afford me this opportunity. The case during its progress, may have appeared trifling to you, the symptoms being for the most part unaccompanied by pain, or much constitutional disturbance, yet, is this condition of the veins, fraught with much possible danger, the chances of purulent termination being by no means remote, and which once established excites conditions of fearful jeopardy, and rarely exempted fatality.

The ward-book reports the case of J. H., a labouring man, aged 27, admitted suffering from idiopathic phlebitis. The appearance of the patient on admission was that of a man throughly out of health, of somewhat anxious aspect, but not suffering any amount of pain. He states that he has felt a tense cord-like swelling in both his legs for the last seven days. There is no want of mobility in the lower extremities. He walks and moves about without pain; but commencing at the internal malleola of both legs, and extending up on the inner edge of the tibia, and between the edge of the belly of the gastrocnemius, a cord-like swelling is felt, which is slightly painful to the touch, and the course of which is marked by a dusky red line. It is evidently the saphena major vein in a state of inflammation. The cord-like hardness extends the whole length of the vein, and is lost only as the vessel disappears under the fascia to join the crural. The same condition exists in the saphena veins of both legs. There is no swelling of the glands of the groin; no wound or any abrasion of surface on the foot, or any part of the lower extremities. Has not felt any rigors. The pulse is 84, soft; the tongue is white and moist; there is no deficiency of appetite; no thirst; no febrile heat of skin; but the urine is dark coloured, and deposits a copious precipitate of the pink urates. He has been at work in the coffer-dam at the Houses of Parliament, working often for hours up to his ankles and knees in water.

He was admitted on the 20th January, and ordered Hydrarg. cum Creta et Pulv. Ipecac. Co., utrq., gr. v., quartis horis. Beef tea diet, and the lower limbs to be enveloped in hot moist flannels, to be repeatedly renewed. On the next day the cord-like tension of the veins had materially diminished, and much less pain was felt on pressure. The dusky-red colour now marks the course of the veins, from the inner ankle to the groin, indicating that some smaller branches, emptying into the main trunk, are here and there likewise affected. On the 23rd slight ptyalism was noticed, and in the course of the afternoon a brisk diarrhœa commenced, which was directed not to be checked unless it became urgent. The remedies were to be repeated. On the 24th the report states, that after many watery dejections the looseness spontaneously ceased, and this day no pain was experienced in any part of the indurated vein, and the dusky-red colour was now confined to the inferior part of the vein. On the 25th the cord-like tension was gradually disappearing, his general appearance had much improved, the appetite, which had not been deficient from the first, had now become craving, and he was placed on an improved diet. On February 1st he was reported convalescent, and discharged on the 2nd.

It may be mentioned as remarkable, that a man, suffering from chronic rheumatism, and in Dr. Kingston's ward, is suffering from a similar condition of the saphena in both limbs. I have no hesitation in referring the origin of this state of the veins to the effect of cold. We did not see this patient during the first period of the attack; we cannot, therefore, determine the amount or nature of the constitutional disturbance

existing at the commencement; at any rate, we are assured of certain circumstances capable of predisposing the system to such disturbance. The exposure of the lower extremities for hours at this season of the year, to the influence of cold and wet, is not an unlikely disturbing cause. Had symptoms of rheumatism coexisted with the inflammation of the saphena veins, as is the case in the patient in Bouverie ward, there could have been no difficulty in associating this state of the veins with the phlebitis accompanying the rheumatic diathesis, and which has been noticed by more than one author. Yet, notwithstanding the absence of all erratic pains, I am still inclined to refer this condition of the veins to a rheumatic origin, the state of the urine presenting all the features of rheumatism, and the exciting causes being in every respect capable of developing most of the conditions and elements of that disease.

Phlebitis from rheumatic causes may be considered as the lightest form of this most serious malady; it differs only from the phlebitis produced by wounds, or by the absorption of animal septic poisons, in that there is less tendency to terminate in purulent formation, a condition that renders these two latter affections of such momentous importance. The plastic contents of the vein in this rheumatic form of phlebitis, either dissolve or liquefy; and being thus removed, are carried away into the general circulating mass, or at most remain as a plug in the vein, becoming semi-organized, and either completely or partially obstructing the circulation through the affected vessel, the numerous venous anastomoses subsequently carrying on the current through their enlarged and dilated canals.

When a disease presents distinct external manifestations, it is convenient to consider it—first, in reference to the local symptoms; and, secondly, as to the extent of constitutional disturbance, accompanying or produced by the local disease. I wish therefore to detail to you—first, the pathological conditions of the inflamed vessels, the cord-like tension of which first arrests our attention; and, secondly, the constitutional conditions, if any, produced by the state of the veins.

It would appear from the pathological researches of the most recent observers, that the inner membrane of the veins in the earliest stage of the inflammatory process becomes discoloured, of a purplish hue, occasionally of a light scarlet, and that this discolouration is not uniformly spread over the inflamed portion, but irregularly—in patches, sometimes presenting a striated appearance. Accompanying this alteration in colour, and as the result of the hyperæmia of the lining membrane of the vein, is the exudation or deposit of plastic lymph, which, forms in layers, each succeeding layer being deposited external to the last, the whole being concentrically arranged, till the tube of the vein becomes completely clogged, and impervious to the current of the circulation. It does not, however, necessarily follow that the vein becomes totally impervious; for the fibrinous deposits do not always continue till the canal of the vessel has become obliterated. The inflammatory process being arrested, the layers of lymph have, perhaps, only lined the canal, and considerably diminished its capacity—not totally closed it. It is now, irrespective of complete, or only partial, obliteration, that the vessel has acquired that cord or quill-like character to the sense of touch, which you felt in this case. The plastic lymph lining the vein is for the most part colourless; it has been derived from the blood, and consequent upon its isolation and deposition there occurs a serous infiltration into the outer tunic of the vein, and not unfrequently extending into the cellular tissue investing the vein. This serous fluid holds in solution the hæmaphæin, or colouring matter of the blood; and it is its presence in the serous infiltrated fluid which causes the dusky-brown red hue that externally marks the course, extent, and ramifications of the inflamed veins.

It may happen that the inflammatory action does not continue with sufficient intensity completely to plug up the canal of the vein; and I think the case before us presents us with an example. When this happens, the circulation is still imperfectly carried forward through the centre of the plastic layers; for as these layers are invariably thrown out from the lining membrane of the vein, and are added to the circumference of the plug, it follows, that for a time, at least, the circulation goes on, the calibre of the vein diminishing as each succeeding layer is added to the circumference of the deposit. As a consequence of the complete obliteration of the vein, the circulation is then maintained by the anastomosing veins.

One of the most important characteristics of venous inflammation is its tendency to centripetal progress: it less frequently extends from trunks to branches than from branches to trunks; and thence progresses towards the heart, the centre of the circulation. This is one of the conditions that causes phlebitis to be of such vital moment.

The subsequent changes that take place in the plastic mass, plugging the channel of the vein, are strictly analogous to those observed in inflammatory products in other parts of the body. One of three conditions must happen:—

1. The fibrinous mass disappears slowly, and gradually becoming dissolved, it is carried away by the restored current of the circulation.

2. The lymph becomes semi-organized, and forms a permanent addition to the inner parietes of the vein: this more frequently happens when the plastic layers have not completely obliterated the channel, but merely lessened its calibre. When this occurs, tense, quill-like hardness persists, and a subsequent examination of the vein would present its walls much thickened, its capacity diminished, and when cut across, the vein would remain uncollapsed, and as an open cylinder.

3. The third and most serious change to which the inflammatory exudation is exposed, is the special tendency that it has to pass into suppuration. It is this tendency which makes phlebitis at all times so hazardous in its consequences; the blood becomes contaminated by the purulent degeneration of the plastic layers, abscesses in different organs of the body, the liver, lungs, and other glands, are the formidable effects, and death the inevitable termination.

It must be borne in mind that the inflammatory process in some forms of phlebitis does not pass beyond the deposit of the plastic lymph, and that no farther *morbid* change taking place, the blood escapes that fearful purulent contamination, which, if once established, rarely terminates otherwise than fatally.

The case we have just seen presents us with an example of an exemption from these terrible secondary consequences; you must, nevertheless, not forget that however trivial and light the symptoms may have appeared to you, a case of inflammation of the veins from whatever cause, must be considered serious, as the tendency to purulent degeneration of the plastic mass is greater than either to its solution, removal, or semi-organization. When purulent transformation of the deposited lymph does not take place, it is often remarkable with what rapidity the plug disappears, and the function of the vein as a permeable tube is restored. In the case under consideration, in the course of a few days, the vein had become soft, and evidently permeable. Hasse states that this change is effected probably by the liquefaction and solution of the plastic mass in the circulating fluid, and a channel by this means is again opened to the sanguineous current, and there are many reasons for supposing that the exuded lymph is not removed by absorption by the vasa vasorum, but is absolutely dissolved in the blood, and carried away into the general circulation. The removal of the fibrinous deposit in this case, and the subsidence of all farther symptoms of inflammation, were consentaneous with the faint indications of ptyalism produced by the small and alterative doses of mercury. From this moment the cord-like hardness disappeared, the veins in the greater portion of their course had become soft and elastic, while the dusky line which marked the course of the inflamed vessel had entirely disappeared.

Phlebitis in all its forms presents us at the outset with all the characteristics of a sthenic inflammation, and the treatment must be based on those principles which experience teaches us are most successful in arresting the results of inflammatory action. A general antiphlogistic regimen must be strictly enforced. Mercurials, with opium, or Dover's powder, are the best alteratives. The lower extremities of this patient were for nearly four days enveloped in hot moist flannels, constantly renewed. The best results have followed this treatment; the patient is convalescent, and the hardened plastic deposit in the saphena veins has nearly disappeared. The amount of constitutional disturbance was but slight; beyond the appearance that the countenance indicated of deranged health, there was no symptom of any moment declaring that the general functions of the chylo-poietic viscera were much deranged; the appetite was not deficient; the bowels not irregular; but the urine was loaded with urates, uric acid crystals were also apparent, and there was a considerable amount of purpurine in combination.

From the absence of much constitutional disturbance, it would appear from this example, that it is not till the terrible condition of purulent degeneration of the plastic lymph has commenced, that any remarkable or characteristic constitutional symptoms are developed. You must bear in mind, however, that the absence of these general symptoms is not to be taken as an index, that little is required to be done, or that the case is trivial, and needs but slight attention. So long as the vein is the seat of inflammatory action, so long as a fibrinous deposit clogs up the canal, suppuration of the plastic mass may be dreaded, not remotely, not contingently, not merely accidentally, but as a change strictly in obedience to the organic laws governing these pathological products. It must be our object, therefore, in the treatment of such cases, to avert if possible this much dreaded mode of termination. This can only be effected by the judicious and persevering application of those remedies that have been already indicated. The period of convalescence must be treated with caution; there is a special tendency to relapse in these cases; the local inflammation then re-appears with an intensity that no remedies can check, and which now passes rapidly and uncontrollably into purulent transformation and inevitable death.

The rheumatic diathesis does not often express itself by phlebitis; yet it is not difficult to understand, that in certain morbid conditions in which the fibrinous elements of the blood are in excess, and a general inflammatory predisposition exists, cold locally and continuously applied to the lower extremities, in a manner favourable to local derangement, may predispose to inflammation of the veins of those parts. There must, however, be a special idiosyncrasy to determine the inflammatory action to the venous tissues, rather than to the fibrous tissues, muscles, ligaments, tendons, or synovial membranes, as is most frequently observed in rheumatic inflammation. In fine, this case teaches us, that under special circumstances, exposure to cold and damp, acting on the rheumatic diathesis, is to be considered among the predisposing causes of idiopathic phlebitis; and that though rarely developing this disease, yet under favourable circumstances, and in peculiar idiosyncracies, these causes are competent to call it forth in its mildest, as well as in its most formidable, aspects.

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(*Fourth Series of Experimental Researches.*)

By William Addison, M.D., F.R.S., Malvern.

XI. Structural Changes produced by Scrofulous Disease.

(*Continued from page* 171.)

A man, aged 37 years, died of hæmoptysis and phthisis. The body was examined forty-eight hours afterwards.

On opening the chest, the right lung was immediately seen to be totally different from anything resembling a healthy lung; it was converted into an ash-grey coloured firm texture, which did not in the least degree collapse upon the opening of the chest, but remained bulging upward, filling the whole of the right cavity of the chest, and adhering firmly at all

points to the costal wall. On attempting to separate the adhesions, the texture composing the lung was found extremely brittle, crumbling down under the fingers like dry gingerbread, and every now and then a cavity containing pus,—sometimes white and sometimes red,—was opened by the separation. The *pleura* in the first place was found altered in vascularity and appearance; it was very much thickened by innumerable layers of a fibrous texture, infiltrated with transparent gelatinous (mucous) matter. The fibres were seen by a lens to be curled or waved, and elastic; in the direction of their length several red vessels traversed between and among them, and their minute branches extended into, and subdivided in, the gelatinous material. The arrangement and size of the vessels in one layer of this fibro-gelatinous texture, bore no resemblance to those of another layer, and in all it differed essentially from the mode of distribution of the vessels of the healthy pleura. In one of these fibro-gelatinous layers I counted with the lens fifteen vessels, pretty nearly equal in size, running side by side a straight or parallel course of an inch or more, without giving off any branches, or receding from, or approaching nearer to, each other; their internal diameters varied from $\frac{1}{50}$th to $\frac{1}{80}$th of an inch, and they were distant from each other, about the $\frac{1}{40}$th. The intervals between the vessels, including the walls of two contiguous vessels, consisted of glistening waved fibres, imbedded in gelatinous matter. Under the microscope this gelatinous or mucus-like matter, the relations of which have been traced in former researches, had the appearance of a fibrous texture, thickly studded with colourless cells; and the red vessels traversing it had no other coats or walls than what were formed by the material itself.

On making sections into the right lung, the normal texture of the organ could no where be found, the whole of it having been transformed into the brittle ash-grey substance before-mentioned. This new and morbid texture was internally partly red, and partly white or grey, both portions containing numerous cavities; those situated in the red parts differing, however, in many particulars, from those situated in the white or grey. The free surface of the walls of the former,—the red, for instance,—was smooth and uniform, covered with a soft, pultaceous, white material, beneath which were large straggling red vessels, visible to the naked eye, ramifying in all directions. The free surface of the walls of the cavities in the white substance was very rough, resembling a miniature rock-work, irregular eminences and projections, and sometimes bands, thrusting out on all sides, partially dividing the cavity into numerous compartments. These irregular walls were here and there reddened in patches by blood-vessels, but altogether the vascularity was much less than upon the smooth walls of the cavities in the red texture. The substance of the lung, wheresoever small portions were examined with the microscope,—whether in the whiter, or as Dr. Williams describes it, *parsnip-coloured*, portion, or in the red,—was found, composed of colourless cells, granular matter, and molecules. The white pultaceous matter lining the surface of the cavities in the red portions of the structure, was a corpuscular or incoherent cellular texture, (nearly solid pus,) and the coats of all the minute blood-vessels which were examined with high magnifying power, were found chiefly or entirely composed of similar objects or cells.

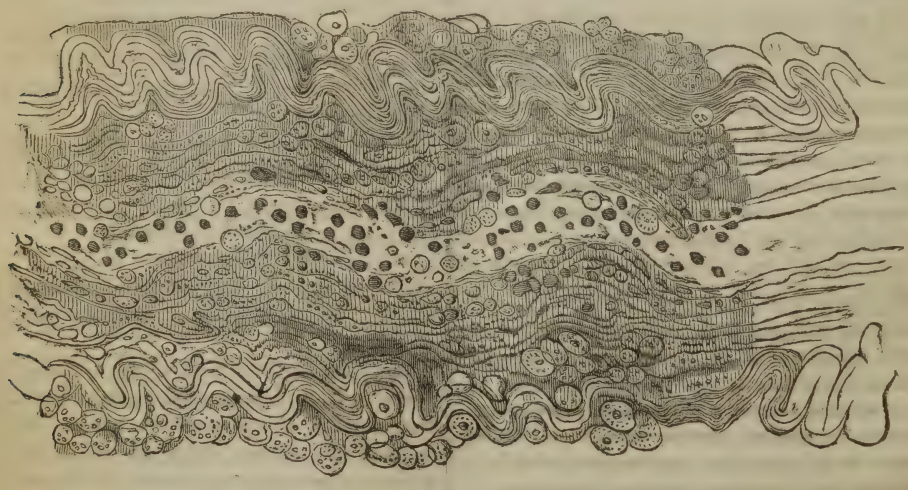

Fig. VI.—A blood vessel, from abnormal fibro-gelatinous texture, on the surface of scrofulous lung.—Case 2,

A girl, aged fifteen years, was seen but once, lying in bed upon the left side, with the knees drawn nearly up to the chin; the eyes were suffused with tears, and the conjunctiva red; the pulse was feeble and quick, the tongue red and dry, and she complained of headache; there was a slight squint in the left eye, and upon trial the left hand and arm were found weaker than the right. These last two symptoms it was supposed were new or recent, for upon inquiry they had not been noticed before. Upon farther investigation it was found that the illness commenced two months before with *influenza*, cough, and pain in the side; these symptoms subsided in about three weeks, but as she remained ill, it was supposed, by those previously attending her, that she laboured under an attack of *bilious* or *typhus fever*. Two hours after the visit I have just described, the patient was seized with convulsions, and died the following day comatose. The body was examined twelve hours after death.

The pia mater was extremely red, all the vessels being turgid with blood. On examining the vessels through a lens, a number of red nodules or points were seen situated upon many of the smaller branches, beyond which the branch was empty of red blood. [In the subsequent microscopical examination it was forgotten to observe what these red points and the apparent obstruction of the calibre of the vessels was owing to.] Numerous semi-transparent granulations were scattered over the texture. The ventricles of the brain contained a considerable quantity of clear limpid fluid, and the fornix and other contiguous parts of the structure were softened. The plexus choroides was very pale and voluminous, and four or five hydatid-like or vesicular-looking bodies, as large as small peas, were adherent to the structure, the pale colour of which strongly contrasted with the highly injected vessels of the *velum* or fold of pia mater with which it is continuous.

The semi-transparent granulations of the pia mater were found, on examination with the microscope, to be composed of a corpuscular or cellular texture, and gelatinous matter, and the coats of a small vessel from an opaque portion of the pia mater, appeared to have the same composition. The pallor of the plexus choroides was found owing to an unusual abundance of the large colourless corpuscles or cells, natural to the texture, and the hydatid-like bodies were groups of similar cells. The softened portions of the brain were composed of multitudes of incoherent cells, resembling pus-cells, which had replaced the nerve-tubes, and destroyed the normal firmness and consistency of the structure.

On opening the chest numerous large red vessels were seen branching over the pericardium, and the interior of the pericardium was found rough throughout to the touch from multitudes of small granulations. The right lung contained many tubercles, and the left lung adhered to the walls of the chest. The adhesions were very brittle, and when broken down, which they easily were, the surface of the pleura, both on the lung and on the chest, was found rough from granulations similar to those within the pericardium.

Upon examination with the microscope, incoherent colourless cells, and but slightly coherent corpuscular or cellular textures, were found to be the chief and characteristic elements of the granulations, of the soft matter of the adhesions, and of the walls of the minute branches of the new vessels.*

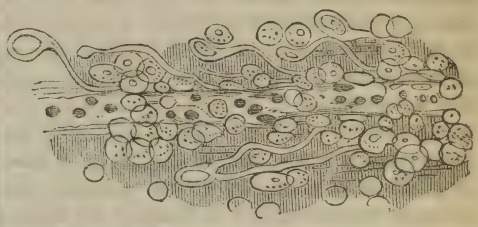

Fig. VII.—A capillary vessel from the pia mater of a child, who died of hydrocephalus. Case not related.

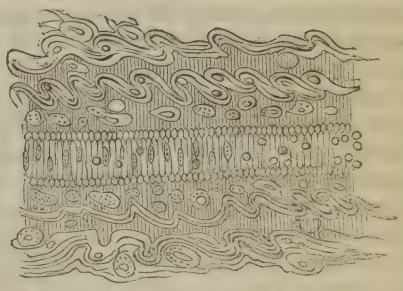

Fig, VIII—Large vessel of pia mater, (normal.)

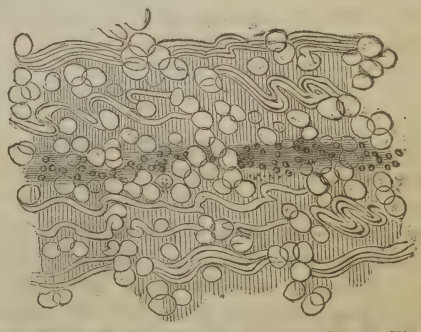

Fig. IX.—A blood-vessel of the same size as *Fig.* 8, from an opaque spot of pia mater. Case 3.

Other cases, of which I have notes and illustrations, might have been added to these, but as they all bear upon the same point,—the replacement of the normal elements of the structure by incoherent cellular forms,

* In making these microscopic examinations, I remove small portions of the textures with as much blood as can be preserved in the vessels, immersing them in a weak solution of salt and water. In this way they may be kept full of blood for some hours, and when the small vessels are examined, the red cells may be seen flowing along them, rendering the parts more distinct.

and gelatinous or tuberculous matter, and are all, therefore, similar to one another—I have deemed the three cases related sufficient to establish the facts upon which my conclusions are grounded; and it appears to me that no one is entitled to disclaim against the conclusions, on the presumption that my microscope is a bad one, or that my eyes see more than other peoples, and at the same time decline to inform me of the truth. It seems hopeless to attempt to make any progress in the knowledge of disease, if, contrary to the rules by which experimental researches are estimated in other sciences, it be allowable in physiology and pathology for any nameless *we* to dogmatize, without offering any evidence to shew that work has been done, and different facts arrived at upon the same subject. However copious and extensive a man's scientific knowledge may be, and however much or long he may have used the microscope on other topics of investigation, he derives from these sources no ground of authority to pronounce judgment, either for or against my facts, inferences, or conclusions.

Now, the first conclusion which it appears to me may at once be drawn from these pathological researches is,—that the deposit of tubercles, or of tuberculous matter, either in the parenchyma of the lung, or in the texture of any other organ, does not explain the pathology of consumption, or of scrofulous disease in general. This corresponds with the fact, now well known, that tubercles may exist to a considerable extent in the lungs, and yet no consumption follows. Tubercles and phthisis have not the relation of antecedent and consequent. These investigations, on the other hand, disclose a vast scene of activity,—new textures, new blood-vessels, new elements, and a busy scene of excretion, amidst which the normal texture disappears, and the natural functions of the organ therefore necessarily cease.

The researches of Shroeder Van der Kolk, and more especially those of M. Natalis Guillot, have shown that a great transformation in the vascular system of the lungs is one of the remarkable phenomena attending the evolution of phthisis. The injections, dissections, and microscopical examinations of the latter especially, have shewn that as the capillaries of the walls of the air-cells, and the branches of the pulmonary artery supplying them, are obliterated, they are replaced by an adventitious vascular system, supplied not with dark and venous blood, but with arterial, derived from the bronchial arteries, and from the vessels of the mucous texture of the air-tubes. In proportion as the tubercles enlarge and soften, this new vascular system spreads more and more, replacing the branches of the pulmonary artery, until their existence ceases to be matter of demonstration. These new-formed vessels, which at a certain period of the disease become incalculably numerous, stop short around the tubercles, without penetrating into their substance. But the case is different in respect of the cavities; they extend into the prominences on the surface of these, and ramify abundantly in, and impress colour upon, the bands so frequently stretched from one point to another of their parietes. If a portion of the wall of a cavity be placed under water, after all mucous and purulent matter has been washed from its surface, this surface is seen studded over with tufts of new vessels, which, taken together, represent a sort of villous structure, as observed with a common lens. "Hence," observes the author, M. Guillot, "it is not only the highly vascular network surroundiag the cavities with its new circulation, that constitutes a striking feature in the anatomy of these excavations, but farther, the terminal tufts or villi which bring arterial blood derived from the aortic circulation into contact with the air, having replaced the normal capillaries which before brought venous blood in contact with the air."*

My microscopical investigations not only corroborate these prior researches, which appear to me to have been strangely neglected, but I think they go farther, and prove that this great vascular transformation is only one of the accompaniments of a great metamorphosis of the pulmonary textures, in which a coherent, elastic and homogeneous cellular texture, with non-secreting capillaries, is supplanted by a brittle, soft, corpuscular texture, with new vessels copiously excreting or discharging corpuscular or cellular forms.

But it has been proved from a minute examination of the condition of the embryo textures, and of the nature and composition of blood, that the law or order of the metamorphosis in the normal growth of the structure is from incoherent corpuscles containing a secreted material, to soft and brittle corpuscular secreting textures, and from these to the coherent, non-secreting, cellular and fibrous; and therefore, *if a coherent, cellular, and fibrous non-secreting texture becomes changed into a brittle corpuscular secreting one, the metamorphosis is retro-grade.*† Whether the incoherent corpuscles or cells, which are the distinctive elements of the new textures and of the coats or walls of the new vessels, and which so abundantly appear in the matter excreted or discharged from them, be the identical colourless cells which previously circulated in the blood, or whether they spring by a species of secondary growth from germs in the morbid texture, is a question that need not now be entered on. It is sufficient for the conclusion just stated that incoherent colourless corpuscles, whether springing from the texture or the blood, with very thin and tender

* See *Observationes Anatomico Pathologici, &c.*, of Shroeder van der Kolk, L'Experience, tom. i., p. 545; and Researches on Phthisis, by Louis, Syd. Soc. Ed.

† The terms secreting and non-secreting are used here in compliance with the common usage, but in all cases it is corpuscles or cells that *secrete* the blood-vessels, and textures *excrete*; the former prepare or elaborate, the latter throw off or discharge.

walls, filled with an elaborated or secreted matter and molecules, and analogous to those seen in the embryo textures, have taken the place of the transparent, coherent, strong and elastic, cellular and fibrous textures. All that need be affirmed is, that corpuscles or cells, apparently identical with those which form the elements of, and are excreted by, the morbid texture, circulate abundantly in the blood, and may be seen adhering to, and altering the character of, nutrient vessels; and these *facts*, established by observation and experiment, are sufficient to explain the origin of the elements which effect the structural changes.

But before this conclusion can be admitted as the basis of the pathology of scrofulous diseases, it is necessary that its foundation on natural laws be substantiated by further investigation.

(*To be continued.*)

OBSERVATIONS ON HERNIA, AND ITS TREATMENT BY OPIUM.

By Butler Lane, M.D., M.R.C.S.E., &c. &c.

Among the most serious emergencies of surgical practice may be reckoned cases of strangulated hernia. This is especially the case in country practice, where there may be lack of counsel to impart confidence in action, and where life may depend on the judgment and energy of a single professional individual. Even in the metropolis, where abundant experience and operative skill are available, it must be acknowleged, that such cases often occasion considerable embarrassment. It has always been an object of surgical science to supersede the necessity of operation, in cases of strangulated hernia; other objectionable circumstances besides the danger, place the operation in question among the foremost of the *opprobria medicinæ*. I am therefore induced to direct the attention of the profession to a method of treatment, which has been attended with such marked success in two consecutive instances, as to convince me that it deserves a fair and extensive trial in the arena of hospital practice.

The plan I am about to advocate, consists in narcotising the patient by the free and continuous administration of opium. Where or with whom this method of treatment originated, I know not, but I shall be happy to surrender the merit of suggestion to any just claimant. When I adopted the practice in the first instance, I had a vague idea of having seen the use of opium in hernia mentioned in some periodical, and my memory did not serve me farther; but from considerations, hereafter to be mentioned, it seemed to me feasible in affording some prospect of relief.

The first case to which I shall refer, was one of oblique inguinal hernia, occurring in a female, about 45 years of age. The previous history was somewhat obscure, but it seemed probable that slight protrusion and incarceration, (probably omental in its nature,) had existed for some time previous to the present period. She was under the care of Messrs. Shelley and Stilwell, of Epsom, to whom I am indebted for most of the following particulars; and when I saw her with those gentlemen, unequivocal symptoms of strangulation of the hernial tumour had existed at least three days. The swelling had enlarged considerably, there was much abdominal pain and tenderness, obstinate constipation, constant nausea, and copious vomiting of decidedly stercoraceous character. The symptoms had suddenly supervened, and gradually increased in intensity. In the first instance, the stomach had retained large doses of cathartic medicine, castor oil, and calomel, though without any aperient effect, but now everything was rejected as soon as swallowed. All the usual medical means available had been unsuccessfully resorted to, and the taxis had been carefully and repeatedly applied. The tumour had now become exceedingly tender, the countenance assumed an anxious expression, and the pulse was accelerated. There could be no doubt that the operation was desirable, and that without delay, but to persuade the woman to submit to it was impracticable. I again employed the taxis unavailingly. A cathartic enema was then ordered, and any farther procedure was remitted till the following morning, when we hoped by other means to induce the woman to undergo the necessary operation.

When I again met Mr. Shelley and Mr. Stilwell, we found all the symptoms had increased in urgency, and the vital prostration was become more obvious. Our patient, however, was no less refractory and obstinate than heretofore. Her danger was imminent, and in fact, death seemed almost inevitable. The state of depression rendered a tobacco enema objectionable; it was, however, agreed to try it, but though its sedative influence was fearfully powerful, yet it did not seem to afford any advantage, no fæcal evacuation being obtained, and the stercoraceous vomiting and other symptoms continuing as before. As a last resource, I then suggested the administration of opium, in doses of one grain every hour, which was agreed to, though with but little anticipation of effectual relief.

I saw the woman next day with Mr. Stilwell, and was agreeably surprised at the change which had taken place. Twelve doses of opium had been administered and she was fairly under its influence, having the appearance of a helpless state of intoxication. She had slept much, and when roused, her answers and conversation were very incoherent. The pulse had increased in power, and diminished in frequency. No complaint was made of abdominal pain, and there was much less tenderness in the umbilical region and the site of the tumour. The sickness had ceased and food had been taken and retained. The improvement was permanent and progressive. A simple enema was

administered that evening, and brought away much fæcal matter. In the course of the day the tumour became spontaneously much reduced in size; for some time subsequently a small swelling remained in the groin, and whether it ever disappeared completely I am unaware.

The second case occurred in the practice of my friend and partner, Mr. Allan, of Epsom, and I am chiefly indebted to him for the particulars. A woman, aged 70, suffering severely with a catarrhal attack, presented symptoms of obstruction of the bowels, and on examination a femoral hernia was discovered in the left groin. She said she had first perceived the swelling two or three months previously, and it had seemed within the last few days to increase materially from the violence of the cough. The taxis and other remedial means were unavailingly resorted to, and the symptoms had existed 48 hours when Mr. Allan requested me to see the patient with him, that we might determine as to the operation. At that period I found the tumour the size of a large walnut, free from heat or pain, neither was there any abdominal tenderness. The tongue was somewhat furred and dry, but there was no great heat of skin; the pulse did not exceed 84, was regular and not deficient in tone. The woman's chief complaint was of intense nausea and violent sickness, coming on with the paroxysms of coughing; any movement or attempt to change her position would also occasion it, and on taking any nourishment, it was immediately rejected; with the continued vomiting stercoraceous matter followed in abundance. I applied the taxis some time, and with considerable force, but unsuccessfully. There could be no doubt as to the nature of the case, and the ultimate necessity for an operation seemed inevitable, but as the constitutional symptoms were not urgent, and the operation was strenuously objected to by the husband, we agreed to some farther delay. A large enema with castor oil was administered, and, beyond a little gruel, no nourishment was to be attempted.

No favourable change had resulted the following morning,—night had afforded no repose, and the retching and vomiting had been almost incessant. The enema had for the most part been retained some hours, but its evacuation had been unaccompanied by fæcal matter. The constitutional depression was more manifest, the pulse had become accelerated, and some pain and tenderness were experienced both in the abdomen and in the tumour. Mr. Allan proposed that the tobacco enema should be used, and in the event of its failure, that the operation should be had recourse to without farther delay. Bearing in mind the success which had attended opiate treatment on the former occasion, I suggested its adoption in the present instance, as there was still great aversion to the operation on the part of the patient and her husband. Mr. Allan acceding to my proposal, one grain of opium in the form of pill was administered every hour.

When we met the following morning eight doses had been taken, and the narcotic influence was manifest, though the medicine was evidently well borne. The pain and vomiting had ceased, but the bulk of the tumour was not diminished, nor had the bowels been moved.

After the administration of four more doses the tumour was found to have diminished to one half its former size, the patient still continuing free from pain and sickness. A large injection of gruel with castor oil was then thrown up the rectum, and ample evacuation of fæces soon took place. The relief was permanent. A small swelling remained in the groin, and still continues, probably containing a portion of incarcerated omentum. In the words of Mr. Allan, "*Thus was this patient saved the risk and pain of a serious operation, by a remedy, every dose of which brought relief and comfort.*"

I shall now venture on a few brief observations in reference to the *modus operandi* of opium in hernia, and my opinions on this subject have emanated rather from a long continued investigation of the action of the various narcotics and sedatives, than from a mere wish to clothe the above isolated facts with an appropriate and well-seeming theory.

The pathological elements of strangulated hernia are two-fold:—on the one hand those connected with the protruded bowel, and on the other those depending on the muscular and tendinous tissues which surround the opening through which the intestine protrudes. That the tendinous structure can only exert a passive influence is generally allowed, and that *permanent* spasm can under ordinary circumstances affect the fibres of the voluntary muscles, or even those which are instinctive or spinal-motor, would not on reflection seem probable; and yet on this latter assumption have all the theories of hernial strangulation been chiefly founded as far as I am cognizant thereof. Now, in a pathological point of view, beyond the visceral extrusion, through a narrow and unyielding opening, I believe the active cause of hernial strangulation to be essentially connected with the intestine itself. Suppose a portion of intestine forced into a cavity of which the neck is somewhat constricted. Now, we know that the general effect of superficial pressure on any portion of the body will occasion a greater obstacle to the venous part of the circulation than to the arterial. The balance of action of the two circulating media being disturbed, the afflux will incline to exceed the eflux, until such time as circulation is completely arrested, when gangrene must take place. In accordance with what I have stated above, any medical attempt to relax the external muscular structures would be unavailing; but on the other hand, if we can relax and

reduce the bulk of the intestinal substance, we might then hope for advantage. Now, let us look at the influence of the various sedatives, and see how far any one of them may be expected to conduce to the desired end. Warm baths and bleeding may lower the general system, and relax the muscular structures, but the result of their employment do not sufficiently indicate a decided bearing on the local morbid state. Antimony exerts a special depressing cerebral influence; it diminishes the power of the heart, and lowers respiratory action; it also affects the contractility of the voluntary muscles, but it does not diminish the peristaltic contraction of the intestines in the first instance, neither does it *immediately* influence the capillaries; moreover, it is objectionable on account of exciting irritation in the mucous membrane of the alimentary canal. Belladonna exerts its chief influence on the voluntary muscles; so likewise does tobacco, which in its cerebral influence will subsequently determine to the heart; over that centre of the circulation, digitalis appears to exert a direct control, but it has no peculiar action on the capillaries. Aconite, on the other hand, seems to have a special relation to the sensitive power, and to exert no direct influence over contractile or motor structures. The diminution or even destruction of organic sensibility appears to result from the action of prussic acid, so as to destroy the connection between action and re-action. Now opium is essentially one of the most powerful sedatives we possess, although undoubtedly stimulation may be primarily consequent on its administration under peculiar circumstances. Its action is very general. When freely administered it relaxes all the contractile tissues, and primarily and essentially those which are involuntary. It soon reduces the force of the circulation, and though at first it may tend to produce a state of capillary congestion, yet as soon as the balance of action between the centre and periphery of the circulation is restored somewhat, the capillaries of the surface and of the membranous viscera will be deficient in their usual contents, and lose their natural irritability. Now, with emptied and inactive capillaries, and relaxed contractile fibre, is it not to be expected that the hernial tumour would become reduced in bulk, motionless, insensible, and flaccid?—the intestinal structure is in fact utterly paralysed, and the state which has caused strangulation being removed, as well as the undue internal pressure by which it was originally caused, may we not fairly hope for the spontaneous reduction of the protruded viscus, even as it seemed to occur in the instances which I have adduced?

Experimental enquiry supports the opinion I have advanced respecting the medicinal influence of opium. If the heart, while yet pulsating, be removed from the body of an animal, the muscular contraction will immediately cease on applying a solution of opium, and the same is the case with the vermicular motion of a portion of intestine. The velocity of the capillary circulation is found to diminish on the application of opium; and where a person is under the poisonous influence of the drug, I need scarcely remark that blisters and sinapisms will fail to produce the slightest irritant effect, so completely is organic sensibility destroyed. In conclusion I may remark, that in my experience, the safest and most effectual method of bringing the constitution under the influence of opium, in ordinary cases, is by the repeated and frequent administration of moderate doses; and I am therefore inclined to advocate the same plan in hernia, care being taken to carry the administration to a sufficient extent.

Since writing the above, the influence of æthereal inhalation, in cases of hernia, has come to my knowledge; whether the medicinal action thereof is superior to that of opium remains to be seen; but be that as it may, the lately recorded facts support my view of the pathology of hernia. Mr. Tuson's case, published in the *Medical Gazette*, is especially remarkable. On the abdomen being opened, large masses of intestine escaped, but on æther being used, the bowel returned spontaneously, apparently collapsing rather than contracting under the medicinal influence.

ON ÆTHER-INHALATION IN TETANUS, WITH A CASE.

By W. H. Ranking, M.D., Norwich.

A careful analysis of the recorded experience of the æthereal inhalation in surgical cases cannot fail to convince any unprejudiced person that a discovery has been made, no matter by whom, which is not surpassed in the annals of the healing art. We now know tolerably well what are the circumstances under which it may be exhibited in surgical practice, and when it should be withheld, but of its effects in medical practice we are comparatively ignorant. It has been suggested, amongst other diseases, that tetanus is one in which the stupifying agency of æther would be of great service, but with the exception of myself, I believe as yet no one has had practical demonstration of its effects.* These effects were, as the subjoined case will indicate, not only not beneficial, but to all appearance injurious.

In a disease so uniformly fatal as tetanus, I regard experimentalism, even in the teeth of physiological deduction, as pardonable, otherwise I should not have ventured upon the inhalation of æther in the present case, for I am induced to believe, from a careful noting of the operation of the agent, that it has no power,

* Since the above was written, two trials of æther in tetanus have been recorded,—one in this country, one in France. In the former some slight relief was thought to have been afforded; in the second death was indubitably precipitated by its use.

at all events, immediate upon that portion of the nervous system which we know to be engaged in the manifestation of tetanic symptoms—namely, the spinal marrow. I am aware that this opinion is at variance with that of some French physiologists, Longet among the number, who maintains that æther does induce insensibility of the spinal marrow as well as of the cerebral lobes, though only secondarily to the latter, and when carried to a degree in itself all but fatal; but I still consider, that *therapeutically* considered, æther cannot be employed in diseases of spinal origin, as granting that it is possible to influence that part of the nervous system, it can only be done at the risk of seriously prostrating the functions of the cerebral portion.

If the spinal marrow either cannot be affected at all by æthereal inhalation, or only as secondarily to the production of deeper cerebral insensibility, than most people would consider themselves justified in inducing, it must be obvious, on reflection, that it is not likely to act beneficially in tetanus, for we know that the functions of the true spinal marrow gain an increased intensity by the abolition of the controlling power of the brain. Such being the case, we might expect that the spasms of tetanus, so far from being mitigated, would be aggravated by the inhalation. This was not actually the case in the instance which I am about to record, for the plain reason that inhalation could not be carried on to the point of inducing insensibility. The mere attempt to insert the pipe into the mouth caused the spasms to reappear; and the first contact of the æther vapour with the bronchial membrane induced such fearful convulsions, that to proceed with it was out of the question. In recording this case, however, I would not omit to state, that the inhalation was attempted with a common bladder and pipe; as the more effective instruments which ingenuity has devised in such abundance, had none of them at the time been brought into existence. The case is briefly as follows:—

A man aged about 60, of intemperate habits, but of remarkably fine and athletic proportions, ran a nail through his boot into the sole of his foot, near the ball of the great toe, while walking across some old timber. The accident gave him no uneasiness until the expiration of a week, when he complained of stiffness in the neck, and placed himself under the care of Mr. Coe, a surgeon of Bury St. Edmunds. The next day the tetanic symptoms were general, and my co-operation in the treatment of the case was requested. On visiting the patient, about eleven in the morning, I found the jaw completely locked, the spasms frightfully violent, and considerable opisthotonos; in fact, every symptom was present of tetanus of the most acute character. Our treatment was commenced with the Cannabis Indica, full doses of which were with difficulty got down; but this medicine was for a period omitted in favour of the æther-inhalation, which we determined to essay. A common bladder and pipe being furnished, and two ounces of the purest æther we could obtain being put into it, the patient was got into a bath at 108°, and the inhalation commenced. The warm water had partially relaxed the board-like rigidity of the body, and the poor fellow expressed some relief, when the attempt to insert the pipe again excited a strong spasm. Being however, anxious to persevere, he contrived to push it into his mouth, but the first breath he drew aggravated the spasm in a tenfold degree, the body became perfectly opisthotonic, foam issued from the mouth, and the man altogether presented so frightful a spectacle that we might fairly have been excused had we desisted from that moment. We, however, after allowing the effects to subside, made one more attempt, when the recurrence of the same symptoms convinced us of the worse than uselessness of the proceeding.

The subsequent treatment need scarcely be alluded to, as my object is solely to point out the failure of the æther, but I may state that he was bled largely and continued the cannabis, with some amendment, and in the evening had a tobacco enema, (half a drachm to half a pint of water,) which acted effectually in relaxing the spasms. A warm perspiration ensued, the patient was enabled to open his mouth to the extent of an inch, and expressed himself as in every respect better. He remained quiet for nearly an hour, with a good pulse, when a sudden spasm seized him, in which he died.

OBSTINATE CASE OF CONSTIPATION.

By John Elliott Wood, Esq., Surgeon, Rochdale.

Nancy Sladen, a married woman, the mother of several children, was seized on February 19th, 1847, with pain in the abdomen, vomiting, hiccough, and other symptoms of strangulated hernia. She had been the subject of irreducible femoral hernia for several years. The hernial tumour, however, though large, was not larger than usual, nor more tender to the touch than the abdomen generally. Pills of calomel with croton oil were administered, and injections used, without producing any discharge from the bowels. The symptoms gradually increased in urgency, and on February 21st the usual operation for femoral hernia was practised, the patient being at the time under the influence of æther. The bowel and omentum were found in a natural state, no strangulation existing.

Large doses of calomel were now administered by the mouth, and injections of castor and croton oils diligently persevered in, without any relief to the symptoms. The abdominal tenderness increased; the hiccough and vomiting continued; there was a remarkable anxiety of countenance.

On February 22nd, a solution of morphia was prescribed, which afforded the patient more relief than anything hitherto had recourse to.

From this time to March 31st, a period of *more than five weeks*, croton oil, castor oil, compound extract of colocynth, large doses of calomel, jalap, injections of croton and castor oils, of turpentine, of tobacco infusion, of large quantities of warm water, friction to the abdomen with castor oil, with turpentine, the cold

douche, every remedy, in short, calculated to produce a purgative effect, was tried without effect. The morphia was continued during the whole time with great benefit. Beef tea, jellies, wine, and eggs, were ordered, and taken with appetite.

On March 31st she felt an inclination to go to stool, and parted with a motion, perfectly natural in consistence and colour; this was followed by several others in the course of the day, till she had discharged a very large quantity of fæcal matter. There was no blood, or mucus, or scybalæ, and no portion of intestine voided.

The incision over the hernial tumour, it should be stated, healed in a week. The night before the re-establishment of the action of the bowels, the hernia became large and painful, but was reduced to its usual size by pressure without difficulty.

The patient is now (April 3rd,) in a fair way for recovery, though reduced in strength and flesh.

Rochdale, Lancashire.

Hospital Reports.

HÔPITAL DE LA PITIÉ, PARIS.

A CASE OF ENGORGEMENT OF THE HEART AND INTERNAL ORGANS, PRODUCED BY A SEVERE KICK UPON THE EPIGASTRIUM, AND FOLLOWED BY SYMPTOMS OF INTERMITTENT FEVER, AND PERIODIC NEURALGIA, WITH REMARKS.

(Communicated by SEPTIMUS LOWE, Esq., M.R.C.S.)

History of the case: present attack; symptoms on admission.—Treatment: its effects; progress of the case; convalescence; cure.—Remarks: importance of percussion; nature of the attack; engorgement of the heart, lungs, and liver.—Cause: "anervismie;" benefit derived from bleeding.—After symptoms: "hypernervismie;" intermittent fever; intercostal neuralgia; periodicity referred to the ganglionic system and spleen.

S. P., a female aged 18, admitted into the Hôpital de la Pitié, under Professor Piorry, March 19, 1847. She is a needle-woman, of the ordinary stature, sanguine temperament, and florid complexion. She is a native of Paris, and has resided all her life in the Rue Mouffetard, inhabiting a small ill-ventilated apartment, and sleeping in the same room with eight other persons. She has never suffered from rheumatism or hysteria. About three months since she had a severe cold, with pain in the epigastrium, and loss of appetite, but she was not put under any treatment. Her health has been generally very good. About six o'clock on the evening of the 18th of March, whilst restraining a patient during an attack of hysteria, she received a severe kick in the epigastric region; she suffered but little at the moment, and continued her usual occupations. About one o'clock in the morning of the 19th, she was suddenly seized with violent pain below the left breast, shooting through to the inferior posterior part of the chest on the same side, with very great difficulty in breathing, and considerable anxiety and restlessness; she had no shivering fit nor other premonitory symptom; she did not receive any treatment, and was brought to the hospital at six o'clock the same morning. At present the patient lies upon her back, rolls her head from side to side, throws her arms about, and moans as if in great pain; the skin is moist and natural; the expression of the countenance is anxious, the lips and cheeks are florid; the respiration is hurried and laboured, fifty-five in the minute; she speaks interruptedly, catching her breath between each word. There is no cough, the physical signs of the lungs are quite natural. She complains of severe pain, (which has continued since one o'clock this morning,) shooting through from the xyphoid cartilage to the spine. She states that she feels a tightness about the chest, and a sensation as if she were being suffocated. There are no external marks of injury in the epigastric region. On auscultation, the heart's beat is found to be slower than natural, there is a slight degree of harshness with the first sound, and the sounds are heard over a larger surface than usual. On percussion, the heart is found to be enormously enlarged, measuring from above downwards four inches and a half, and from base to apex five inches and a half; the dulness is very strongly marked; the aorta is also distended; the pulse is laboured and compressible, seventy in the minute. There is no nausea nor vomiting; the large intestines are filled with solid matter, and the stomach is distended with gas; the bowels have not been moved for the last eight days; the liver is somewhat enlarged; the spleen is of the usual size; the urine is natural in quantity and quality; the catamenia are regular.

The extent of the heart being marked out upon the skin with nitrate of silver, Professor Piorry ordered the patient to be bled to the amount of thirty-two ounces; during the bleeding she experienced great relief, and at the conclusion she expressed herself nearly free from pain; the dyspnœa was almost entirely removed, but there still remained some degree of tenderness in the epigastrium. On again percussing the heart, it was found to have diminished to the extent of an inch from above downwards, and three quarters of an inch on its left border; the dulness was much less intense in its character; the aorta was considerably lessened, and the liver was also diminished about half an inch, both on its inferior and superior borders; there was no tendency to syncope, nor was there any sensible effect produced upon the patient's strength; the pulse mounted to eighty, and became firmer, and more natural. Ordered to abstain from all food, and to have a purging enema.

Vespere. About five o'clock she was again attacked with severe pain and dyspnœa. Ordered a grain and a half of opium.

At eleven o'clock the opium was found to have had not the slightest influence in subduing the symptoms, and they had, in fact, become almost as urgent as on her first admission; the heart was again enlarged to about midway between the first limitation and the one made after the bleeding. Ordered to be bled to the amount of thirty-two ounces. After the second bleeding the extent of the heart was found to be diminished considerably within the limitation made

after the former bleeding, and to be, in fact, almost in its normal condition. The distressing symptoms were again completely removed, and the patient obtained a few hours sleep.

20th. About three o'clock this morning she experienced a return of the pain and dyspnœa, but less intensely than before. The heart was found to be in its normal condition, so that a third bleeding was not deemed necessary. A warm bath was ordered, which succeeded in removing the distressing symptoms. At present she is quite calm and composed, but complains of tenderness in the epigastrium and left intercostal spaces; the pulse is regular, compressible, and 78; there is considerable tenderness on pressure over the sixth, seventh, and eighth dorsal vertebræ; the bowels have not yet been relieved. Ordered a warm bath, a mustard poultice to the epigastrium, and a purging enema.

21st. The pain is greatly relieved; the bowels have been moved once; the tongue is slightly furred; no appetite; heart in its normal condition; pulse rather weak and compressible. Ordered low diet. Continue the warm bath and enemata.

22nd. The countenance is again anxious; there is considerable jactitation, interruption in speaking, and catching of the breath. There is not the same kind of dyspnœa which was observed on her admission. She complains of violent lancinating pain, darting through from the epigastrium to the left intercostal spaces and spine, so that she cannot fully expand the chest, or take a deep inspiration, without great agony. The heart continues in its normal state; there is no harshness with the first sound; the large intestines are still filled with fæcal matter, and the stomach is distended with gas. Ordered thirty leeches to the epigastrium, followed by a large linseed poultice; friction over the abdomen with olive oil; a blister over the spine, to be dressed with a quarter of a grain of hydrochlorate of morphia; a purging enema, and a warm bath.

23rd. She had another attack of the same nature last night, which lasted several hours. The bowels have been freely relieved; the pulse is somewhat fuller, and quite regular, 80; there is still considerable tenderness in the epigastrium and spine. Ordered five grains of sulphate of quinine every six hours, in the intervals of the attack.

24th. The attack commenced last night about ten o'clock, with well-marked symptoms of intermittent fever; shivering, which contined ahout an hour; heat, which lasted about an hour and a half, followed by sweating. This was succeeded by the same kind of intense pain as before. Continue the quinine.

25th. She again had an attack last night of the same nature, and at the same hour as the former one. She was ordered ten grains of quinine, which immediately arrested the symptoms, and she remained free until the following day.

26th. There is still considerable tenderness in the epigastrium and spine; the heart retains its normal condition; the bowels are regular; the appetite improved; the tongue is clean. Ordered to continue the quinine and warm baths, and apply a blister to the epigastrium.

From this time until the 29th, the patient had an attack every day, but each day it became shorter and less intense; the tenderness in the epigastrium and spine continued, and she complained of some degree of feebleness.

31st. The tongue is clean and moist; the appetite has returned; she has not had an attack since the 29th. Convalescent. Full diet.

April 2nd. Cured.

Professor Piorry, in remarking upon this case, observed, that if we consider the astonishing progress medicine has made within the last few years,—if we look at the rapid strides it has taken towards perfection, and the degree of certitude in the investigation of disease which is now obtained, we can have no difficulty in admitting it to be a "veritable science;" while chemistry and physics are limited by certain and peculiar laws, or carried away into abstract theory and speculation. Medicine has arrived at such an amount of accuracy and exactitude, that by the assistance of anatomy and physiology, on the one hand, and by that of auscultation, percussion, the use of the speculum, &c. &c., on the other, we can now measure and mark out the different organs with the greatest nicety and precision; and by reasoning upon, and comparing them with, the natural condition, we may detect the almost slightest lesion, and arrive at results the most positive and satisfactory.

The case before us illustrates most admirably the truth of these observations, and is another amongst the many proofs we have lately had of the utility and importance of percussion, and an "organo-pathological" investigation of disease, showing most clearly the surprising light they often throw upon phenomena apparently the most obscure.

This patient was admitted with most distressing symptoms of dyspnœa and troubled circulation, following a severe kick upon the epigastrium. On auscultation nothing abnormal was detected in the lungs, there was a slight harshness with the heart's first sound, and the heart's impulse was extended over a larger surface than natural, but there was nothing positive to point out the true nature of the case. On percussion the heart was found to be greatly enlarged, and the dulness more marked than usual, but it retained its ordinary form. Could it be effusion into the pericardium? Certainly not: for, in the first place, the bruits were not distant or indistinct; 2nd, the rapidity of the attack, and gravity of the symptoms, prevented the supposition; and, 3rd, the shape was altogether different to what is observed in hydro-pericarditis, where, according to numerous experiments made by Professor Piorry, both upon the living and dead subject, the dulness is found to extend upwards and outwards to the left side, and to assume a figure totally different to what is observed either in the normal or the hypertrophied heart.

What then was the true nature of the case? Evidently engorgement of the heart and great vessels, and consecutive engorgement and congestion of the lungs,

liver, and internal organs; and this opinion was rendered more certain by the effects of the treatment, for Professor Piorry has proved, from observations made upon a great number of cases, that *the heart and liver, when engorged and congested, will diminish under the effects of a full bleeding, just as the spleen is observed to contract on the administration of quinine.* But what was the primary cause of this engorgement? Injury of the pneumogastric nerves. We know that the effects of injury of a nerve are partial paralysis, or "anervismie," cramp, and congestion of the parts supplied by that nerve, and this we find to have been the case here; the terminating branches of the right pair being injured, the stomach is first affected, and becomes filled with gas; by reflex action the effects are carried to the heart, its force is lessened, and its energy diminished, and thus being unable to entirely empty itself at each systole, it becomes gradually more and more distended; as the distension goes on, the muscular fibres loose in a great measure their power of contracting; the blood not being propelled onwards, accumulates in the lungs, venous system, and liver. By lessening the amount of the circulating fluid, the heart is emptied, and the blood soon again flows freely through the lungs and liver; and the heart, although its force is still considerably diminished, is again enabled to contract upon and propel this smaller quantity of fluid. But it cannot be expected, that after this enormous distension it will at once recover its former tone; it must have time to regain its lost energy; before this can occur the blood again accumulates in its interior, and embarrasses its action, thus requiring another large abstraction of blood; after which we find it was not only enabled to regain its normal condition, but having now sufficient time to recover its lost force, it continues to act freely and regularly upon the diminished quantity of circulating fluid.

Again, what was the cause of the symptoms of intermittent fever, and exalted nervous sensibility or "hypernervismie"? Injury of the sympathetic nerves. Thus, no doubt, the solar plexus is injured, its sensibility exalted, radiates to the phrenic nerves, causing pain in the epigastrium, to the intercostal spinal nerves, inducing pain in the spine and intercostal neuralgia, so that the patient could not elevate her ribs nor depress the diaphragm without great pain, and thus producing symptoms greatly resembling those of angina pectoris. Again, radiating to the splenic nerves, inducing symptoms of intermittent fever, and determining the periodicity of the neuralgic attacks, for Professor Piorry affirms, that, *we almost never have lesion of the spleen or the nerves which supply it, without some symptoms, more or less marked, of intermittent fever or periodic neuralgia*; and this opinion is strengthened by the effects of the treatment, for we find that the attack was immediately cut short by a large dose of quinine, and the patient completely cured by its continued employment.

It may appear strange to the English practitioner, that in this case, the colon was not at once emptied by a brisk purgative, but on considering the condition of the stomach, which was filled with gas, and partially paralysed, it will be seen that the use of purgatives was quite contraindicated, and that the best method of relieving the bowels was the friction over the abdomen with olive oil, and the employment of purging enemata,—the means so much insisted upon by the French physicians in almost every case where there is no imflammation of the viscera.

Paris, April 3, 1847.

PROVINCIAL
Medical & Surgical Journal.
WEDNESDAY, APRIL 21, 1847.

The popular inclination to remark and speculate upon the weather and its effects, as manifested in our daily salutations and conversation, is singularly at variance with the actual state of knowledge on the subject. We are all more or less disposed to comment on atmospheric variations,—to anticipate their occurrence and nature,—to give due credence to every busy weather-prophet who believes himself able to foretel a coming change, and to draw from such predictions, conclusions of future weal or woe; but there are few who follow the course of careful observation, and still fewer who avail themselves of recorded facts, or attempt in a philosophical spirit to deduce the laws on which this part of the system of nature is governed, with a certainty and precision as unerring as those which regulate the motions of the heavenly bodies.

There are various reasons for this neglect of genuine philosophical investigation on a subject in which all the world professes to be, and is, hourly and deeply interested. The problem to be solved involves many conditions, requires multiplied observations carefully followed out for long periods of time, which must be made by many different individuals differently circumstanced as to locality, and these observations must be accurately comparable together. The limits of error are therefore necessarily wide, and the intricacies of the subject such perhaps as not to be included within their influence. We are not however, here, to enter upon a treatise of meteorology; nor is it intended to develope the causes why the meteorologist has hitherto failed to detect the laws which regulate atmospheric changes. The medical philosopher is not called upon to take upon himself to supply the short-comings of a science, which would require for its elucidation the devotion of a whole life. It is, however, within his province to make use of such meteorological details as admit of ready observation, and to endeavour to trace the effects of the varying conditions of the atmosphere in which we live, on the human constitution, and their relations with disease.

Certain of these effects are, it is presumed,

well-known; the prevalence of pulmonary catarrhal affections in the seasons of winter and early spring, and of dysentery, diarrhœa, and cholera at the close of summer and in autumn, is among the established facts of medicine, and has long been attributed to atmospheric changes. Very loose ideas, however, have been entertained of the relation which the condition of the atmosphere in respect to its weight, temperature, moisture, electric state, &c., bears to the prevalence of disease. How far the influence of these physical agents may be primary or secondary, or whether other conditions, which may be termed concomitant, are not concerned, does not always appear. To take an instance, the autumnal gastro-intestinal affections have long been popularly attributed,—and be it remembered that the popular opinion of one age is very generally the expression of the experience, or presumed experience, of past ages,—to the ingestion of certain fruits; the plum season has been termed the doctor's harvest, and an abundant supply of stone-fruit has very commonly been considered the source of much professional emolument. But the experience of last year shews that the consumption of abundance of plums and the presence of intestinal fluxes, however generally they may be concomitant, in respect of time, are not always to be looked upon in the relation of cause and effect. With a very scanty supply of stone-fruit, we had the usual autumnal bowel complaints most extensively prevalent throughout the country, and unusually severe. We may dismiss, therefore, the popular opinion on this point as a popular error, while we must look elsewhere for a cause of the prevalence of intestinal affections in summer and autumn, than to the use of a superabundance of vegetable productions.

The question will then recur, whether the unusual heat and dryness of the preceding summer season were not, one or other, or both, the direct cause of the prevalence of intestinal affections, and consequently, whether these conditions may not always be more or less influential in the production of the same effects in the plum season, whatever may be the supply of that fruit. This is a point for meteorological research.

The real agent, whether cold, humidity, rapid changes of temperature, or other atmospheric condition, in the production of the catarrhal affections of winter, is another subject which requires investigation on similar principles. These affections have been very prevalent and severe during the severe season now drawing to its close, but they have been also prevalent in other seasons of less actual severity. From the admirable reports on the sanatory condition of Paris, published in the *Gazette Médicale*, for 1846, it would seem to be established that the weight and temperature of the atmosphere, whether considered absolutely or in reference to their variations, do not appear to exercise any appreciable influence on health. The degree of humidity of the atmosphere, and the direction of the winds, on the contrary, seem to exert a well-marked influence. Yet if we attempt to trace the effects of temperature and pressure in their extremes, as recorded by various travellers in the arctic regions, in tropical countries, and on the heights of the Andes or Himalaya range, we shall find that both exercise an immediate and direct influence, and it is therefore not an unfounded presumption that a minor effect must be produced by both, within the limits of such variations as occur in our own country and under our own observation.

These, then, are the questions which the medical meteorologist has to determine. Observations are required to attain this desirable end, and we rejoice to see the attention of several of the members of the Provincial Association directed to this point. To appreciate the effects of any one morbific agent on the public health, it becomes necessary, as far as practicable, to isolate it from all others; this can only be partially accomplished, but the end may be attained with much more effect than has hitherto been done. Meteorological observations, with a view of ascertaining the influence of atmospheric changes on the health ought to be carried on in the healthier districts, altogether removed from the influence of such causes of disease as result from over-crowding of the population,—from the accumulation of animal or vegetable miasmata,—from the exercise of arts or manufactures, known to be injurious to health and longevity. The locale must, therefore, be far removed from the influence of the great-town system, and the observations should be carried on chiefly in agricultural districts. With a view of estimating the effects of temperature and pressure, they should be instituted in different localities, some of which may be on the general level, in the most northern and most southern parts of the country, others on different levels; some inland, some maritime. In this manner we may hope to be able to isolate, to a certain extent, even the more general physical agents; and by recording also the diseases amongst the denizens and cultivators of the soil, readily ascertainable from the records of the union medical officers, to estimate their effects.

Review.

On Tumours of the Uterus and its Appendages, (Jacksonian Prize Dissertation.) By THOMAS SAFFORD LEE, Esq., M.R.C.S.E., &c., &c. London, 8vo, pp. 274.

If we were called upon to name the department of pathology, in which the most solid advance has of late years been made, we should without hesitation point to the diseases of the female organs of reproduction. Although we have not exactly grown grey in the practice of our profession, we can, nevertheless, remember the time, when all but the more palpable forms of uterine disease were a dead letter to the majority of practitioners, and to those who pretended to some skill in such matters, the finger was their best agent in diagnosis, and astringent injections their chief means of cure. This reproach, however, cannot now attach either to the multitude, or the individual medical practitioner, excepting by his or their own culpability, for the more general use of the speculum vaginæ, and the publication of such works as the present, have operated in introducing into the study of uterine diseases, a precision, both of diagnosis and treatment, which is only equalled in the diseases of the eye.

Mr. Lee's volume is one of a class of which we would fain see more frequent examples, and we think that the College of Surgeons has displayed a sound judgment in according to it the Jacksonian Prize. It is not like too many practical treatises, a mere compilation, full of crude speculations and hasty generalization, but one which is characterized by so patient an examination of the subjects discussed, and such an evident desire on the part of the author not to move one step in advance of his facts, that it will not fail, we are assured, in impressing the reader with an entire confidence in the writer's truthfulness and capacity for correct observation.

The matter contained in the volume is distributed under three divisions.

1. Tumours of the uterus, comprising tumours of the walls of the organ, polypoid tumours, cauliflower excrescence, and malignant tumours.

2. Tumours of the ovary.

3. Tumours of the vagina and external organs.

Under the first division the author gives us a very complete history of the various benign and malignant growths to which this important organ is subject, commencing with the fibrous tumour, and taking in succession polypoid tumours, soft polypi, cauliflower excrescence, and encephaloid. As a means of diagnosis of all forms of uterine tumour, he speaks favourably of Dr. Simpson's uterine sound, by means of which he states that the important question of the attachment of the growth to the fundus, and of the adhesion or non-adhesion of the organ to the neighbouring parts, may be satisfactorily determined. He however, warns the reader, that in inexperienced hands this instrument is not devoid of danger, and that violent inflammation may be occasioned by its use.

In reference to the operation for the removal of uterine polypi, the author is at variance with Dr. Montgomery and others as to the dangers of incision. He finds, and we may be sure that in an essay like the present, every available source of information has been searched, that there are at most but two cases on record in which the patient has died from hæmorrhage consequent upon excision of a polypus. The fears of the surgeon have been, we believe, most unnecessarily excited in reference to this operation, and we regard Mr. Lee's statement as well calculated to restore his confidence.

We could easily, and with much satisfaction to ourselves, lengthen the notice of this valuable essay, by the mention of many other subjects treated of in the first part, but as we wish more particularly to direct the reader's attention to the chapter on ovariotomy, we shall here merely state that the diagnosis of uterine polypus, the description of the various modes of operating for their removal, and the chapter on cauliflower excrescence, are particularly worthy of perusal.

The diseases of the ovary occupy the second part of the work, and as the subject is one which has recently been invested with peculiar interest, we shall allude to the author's well-digested opinions on its different bearings at some length. It is a common opinion that encysted dropsy of the ovary attacks females indiscriminately, whether single or married. Mr. Lee finds, on the contrary, that the married are the more liable of the two; of 136 cases, 88 were married, 11 were widows, and only 37 single. These results are certainly opposed to our previous impression, but as we have chapter and verse for this, as for all Mr. Lee's assertions, we are bound to receive them with respect. Another very general opinion exists, that ovarian dropsy affects the left ovary more than the right. This opinion is also reversed by Mr. Lee's investigations.

The pathology of ovarian tumours, the anatomical details connected with the structure of the cyst, the symptoms, diagnosis, and treatment of the disease, are so many points upon which we might with advantage dilate; our space is, however, too limited to allow of our noticing them at the length they deserve, we shall, therefore, devote what space remains to the consideration of two very important subjects connected with the treatment of the disease—namely, the operation of tapping and that of ovariotomy. On both these subjects Mr. Lee speaks *ex cathedra*, and it is but common justice to him to admit that the pros and cons of each operation are most clearly laid down.

The operation of tapping is shewn to be but at best a palliative of very doubtful value, and to be, moreover, in many cases, surrounded by positive and immediate dangers. The consequences, too, of the operation,

are not more favourable, for Mr. Lee finds, that out of a given number, one half died within the space of four months, and that of the latter, half were only tapped once. The cause of death is attributed to inflammation of the sac or peritoneum. These results are exhibited in a table at page 177.

We now come to the operation of excision of the ovary as a curative measure, and here we find Mr. Lee's information to be both extensive and accurate. We must, however, refer the reader to the original for the greatest portion of the details on various matters connected with the operation, contenting ourselves with the following list of conclusions, to which the author has been led by a candid review of the subject:—

"1. That from the difficulty arising in the cure of this disease, the operation of extraction of the cyst has been proposed and performed 114 times, of which number 74 have recovered and 40 died, making the average mortality one in three nearly.

"2. That of these 114 operations, in 24, or rather less than one in five, the operation was obliged to be abandoned, either from extent of adhesions, from the tumour being an uterine or omental one, or from there being no tumour at all, proving indisputably *the difficulties of the diagnosis.*

"3. That in the 90 cases where the tumour was removed, nearly one died to three recoveries.

"4. That the diagnosis of ovarian tumours is very obscure as regards adhesions and the character of the tumour; thus adhesions existed in 46 of the 81 cases where the fact is mentioned.

"5. That where adhesions existed, the mortality was greater, being one death in 2¼.

"6. That the principal recorded causes of death, where it took place soon after the operation, are hæmorrhage and peritonitis.

"7. When death takes place in consequence of the operation it is very rapid. Of 30 patients 14 died within 36 hours, and 25 within a week.

"8. That the character of the disease is of importance with regard to its mortality. In the case of hard tumours the mortality was more than one in two. Of the 16, 9 were cured, 7 died. In 5 the tumour was not removed. When the tumour was composed partly of fluid and partly of solid matter—viz., in 65 cases, 44 were cured, 21 died, and in 14 the tumour was not extracted, making the mortality less than one in three. So that encysted dropsy is more favourable for the operation than hard tumours of the organ.

"9. That as regards the mortality of the two operations, in 85 cases where the major operation was performed, 50 were cured and 35 died, making the mortality 1 to 2½; in 23 where the minor operation was performed, 19 were cured and 4 died, making a mortality of one in six.

"10. That in one of the cases operated upon the tumour was malignant, but that encysted dropsy is not malignant in the ordinary sense of the word."

We now take leave of our author, with a strong conviction that he has written upon a subject which he thoroughly understands, no mean qualification in the present days of medical scribbling; and we most cordially recommend his work as one which should form part of the library of every man who is desirous of improving his professional knowledge. We could wish that this class were more numerous, for it is really painful to meet such numbers of *soi-disant* practical men, who not only do not read, but who make it their silly boast that they do not, hoping, no doubt, that such gasconading may lead to the impression of their own wonderful and innate sagacity.

Lecture, introductory to a Course of Clinical Medicine delivered in the Theatre of Queen's College, Birmingham, on Tuesday, December the First, 1846. By Samuel Wright, M.D., Edin., Physician to the Queen's Hospital, and Professor of Clinical Medicine in Queen's College, Birmingham, &c., &c. London. 8vo., pp. 23.

We are induced to notice this lecture by the Clinical Professor of Queen's College, Birmingham, chiefly because it emanates from one of our Provincial Schools. The observations of its author are highly judicious, and embrace a brief summary of what is expected and required of those entering into the medical profession, to render themselves competent to the serious duties on which they are about to embark. "There is no nobler profession than ours," observes Dr. Wright, in his concluding remarks, "and there is none more responsible. There is something awful in having to take charge of human life: it tells us that we have both a moral and a medical duty to perform to our patients. Never look to the worldly condition of individuals, to know how much professional attention you are to pay them, and what claims they are to have upon your sympathy with their sufferings and anxiety for their welfare." We regret we have not space for the entire passage; it is replete with the highest principles of medical ethics, and happy will it be for the students of the school if such principles seek deep into their minds, and become those on which they shall hereafter be guided in the exercise of their professional calling.

Proceedings of Societies.

BATH AND BRISTOL BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

Quarterly Meeting held at Bristol, Tuesday, March 23, 1847, Mr. Ormond in the chair.

There was a very full attendance, amounting to nearly fifty members and visitors.

Dr. Kay, having expressed his extreme regret at the loss the Society had lately experienced in the death of Dr. Bompas, proposed Mr. Nathaniel Smith as President-Elect, to supply the vacant office. Mr. Estlin seconded the proposition, which was carried unanimously.

ON THE RESPIRATORY FUNCTIONS: USE OF THE SPIROMETER.

Mr. Hutchinson, of London, having kindly offered to make some remarks in illustration of his paper "On the Capacity of the Lungs and on the Respiratory Functions," and to explain the use of the Spirometer,

then gave a very interesting lecture, illustrated by numerous tables and diagrams, on the respiratory functions, of which the following is an epitome :—

Nothing was correctly known upon the functions of respiration previously to the discovery of the circulation of the blood, the pressure, and composition of the atmosphere, so that our present knowledge upon this subject is comparatively of modern date.

Physiological experiments upon respiration have been so limited, that the student is perplexed with views differing from each other. Two circumstances should be considered before he can correctly draw a conclusion from any research, at least of a pathological or physiological nature :—First, with reference to the number of experiments ; and second, with reference to collateral observations upon the human frame. One where the investigation demands for its solution a multitude of experiments ; another where a very limited number at once establishes the point. The chemist, by *one* experiment, determines the *presence* of carbonic acid gas in the breath ; but the physiologist requires *thousands* of experiments to determine the *quantity* of respired air.

With reference to collateral observations, our comprehension of time, space, and weight, is relative ; no isolated observations in nature, if strictly considered, can be of much value, because a combination of circumstances is precluded. The medical man feels the pulse, auscultates the chest, examines the tongue, observes the countenance, desires to know whether the secreting organs are acting in excess or in deficiency, the sleep natural, the appetite good, &c. ; and upon *combining* these data, he grounds his opinion, and the more numerous his collateral observations, the better he is able to venture his diagnosis. An isolated observation upon two men, touching the quantity of air expelled at one expiration, varied from 80 to 464 cubic inches ; this observation, when viewed alone, is of little use, but the matter is more comprehensible when we add the collateral observations of their height and weight, for by arithmetically reducing one man to the size of the other, the shorter man breathed *within* one cubic inch of what was determined by calculation from the collateral observations. The physician, the pathologist, or the physiologist, will gain little knowledge by weighing and measuring the different organs, if he, at the same time, omit taking the height and weight of the body from whence these organs were taken. The development of man is regulated by some certain and constant capacity or measure of his digestive system, therefore to weigh the constituent parts and omit measuring the whole human frame, is like storing up the measurement of doors and windows without reference to the size of the edifice from whence such observations have been made.

Respiration resolves itself into two grand heads,—Chemical and Mechanical ; our attention is here to be directed to the latter.

The object of this research is to detect pulmonary disease in as early a stage as possible. That the *sounds* of respiration are modified by disease is now generally believed ; it may also be demonstrated that the *quantity* of respired air is also modified or diminished by disease, so that having determined the healthy quantity, the *presence and extent* of pulmonary disease can be measured by the *difference*, and that probably earlier than by any other means.

The subject of this research resolves itself under the following heads :—1st. The quantity of air expelled from the lungs, in connection with other physical observations on the human frame. 2nd. The absolute capacity of the thorax, with cubic, superficial, and longitudinal measurements. 3rd. The respiratory movements and mobility of the chest. 4th. The inspiratory and expiratory muscular power. 5th. The elasticity of the ribs and estimate of the voluntary muscular power. 6th. The effect of decussating, diametric, and oblique power, in reference to the function of the intercostal muscles. 7th. General and practical deductions, to detect disease by the spirometer, with the method of its application. In this abstract the first and last heads only are touched upon.

In determining the healthy standard of respiration, upwards of 2000 men, from 20 different occupations in life, have been examined as follows :—The number of cubic inches given by a full expiration, here denominated the VITAL CAPACITY—the power of the inspiratory and expiratory muscles—circumference of the chest over the nipples—the height and weight—the pulse and number of respirations (sitting)—the age—temperature of the expired air,—and, lastly, general remarks on the vocation and appearance.

VITAL CAPACITY.

Of the quantity of Air expelled from the Lungs.—Man at rest breathes a very limited quantity of air, but by the *deepest expiration immediately following the deepest inspiration* a very considerable quantity can be expelled. To this quantity we affix the term *vital capacity*. To determine this, an instrument, the spirometer, has been constructed, and also a convenient form of scale and standard for taking the height and weight.

To measure the vital capacity, the person must stand perfectly erect, with the head thrown well back, slowly and effectually fill the chest, then as slowly and effectually expel all the air he can into the spirometer, where it is measured.

The vital capacity in man is a *constant quantity*, and is modified by four circumstances,—by HEIGHT, by WEIGHT, by AGE, and by DISEASE.

Effect of Height.—The standing height, and the vital capacity, bear a strict relation, so that by measuring the height of a person, the quantity of air can be determined that *should be breathed* as *necessary* to health. "*For every inch of height, (from 5ft. to 6ft.,) eight cubic additional inches of air at 60° are given out by a forced expiration.*" In measuring the height, no allowance is made for the shoe-heel, nor in weighing, for the weight of the clothes. Let the observation for measuring the vital capacity be made three times, and the greatest noted as the quantity sought for. When an air-bag is used instead of the spirometer, then the mean for the three observations must be taken.

TABLE OF REFERENCE

For the healthy vital capacity in the erect position calculated at the temperature of 60° (Fahr.)

Height.	Vital capacity.	Height.	Vital capacity.
ft. in. ft. in.	cubic in.	ft. in. ft. in.	cubic in.
5 0 to 5 1	174	5 6 to 5 7	222
5 1 „ 5 2	182	5 7 „ 5 8	230
5 2 „ 5 3	190	5 8 „ 5 9	238
5 3 „ 5 4	198	5 9 „ 5 10	246
5 4 „ 5 5	206	5 10 „ 5 11	254
5 5 „ 5 6	214	5 11 „ 6 0	262

Thus, if the height be *above* 5ft. 7in. to 5ft. 8in.. the vital capacity should be 230 cubic inches, if *above* 5ft. 8in. to or *including* 5ft. 9in., 228 cubic inches, and so on. If we recollect any one quantity in this table, the vital capacity at any height can be readily called to mind. For example, at the height of 5ft. 8in. the vital capacity is 230; for every other height add to or subtract 8 cubic inches from 230, which will be the quantity sought for.

Curiously, from this table of stature, we have a direct guide to measure the *healthy* vital capacity, and that through the most active period of life, which may be considered as forty years, from 25 to 65.

The stature does not vary but at the extremes of life, whereas the weight may differ and oscillate to an *enormous* extent in the brief period of a few months, therefore were we to combine the weight as a *guide* to measure the vital capacity, we should be encumbered with calculations for correction too numerous and uncertain to be of much value.

The spirometer is constructed to hold a vast quantity of water, to reduce the expired air (without calculation) to as nearly 60 degrees as possible; but in the extremes of the season, our rooms differ from this by many degrees, therefore a table of the correction for temperature is here introduced. The temperature is measured by any thermometer in the room, not necessarily connected with the spirometer.

The vital capacity, as given in the above table, will be observed to increase in arithmetical progression, the series derived from observation (which for comparison is placed in juxta-position in the memoir,) corresponds so nearly to this, that the arithmetical series becomes the best guide. So strict is the relation between the vital capacity and the height, that an opinion may be given, touching the physical development of men now "no more"—thus, Dr. Jurin and Dr. Stephen Hales measured about 5 ft. 8 in., and were between 10 and 11 stone in weight, Davy about 5ft. 7 in., Goodwin under 5 ft. 7 in., and Kite upwards of 6 ft. This legitimate conclusion is gathered from the collateral observations, though their height is no where mentioned.

[A table for the correction of temperature in measuring the vital capacity was here exhibited.] To take an instance, if the vital capacity measures 230 cubic inches when the room is at the temperature of 72°, the correction will be 224, at the temperature of 60° (about 1-500 difference for every degree).

Air-bags are constructed so that any person can be examined at home, and afterwards the bag can be adapted to the spirometer for measurement.

Size of the Chest.—There appears, as yet, no direct relation between the circumference, breadth, or depth of the chest, and the vital capacity. A chest 40 inches and one 30 inches in circumference, or a deep and shallow chest, in men of the *same* stature, is expected to measure the *same* vital capacity. A man may expel more air from his lungs than the whole cubic space allotted for the organs of respiration as when measured at death, or a man in health may expel much less air than the cubic measurement of this space. Two men of *different* heights, yet who *sit* the same height, and measure the same round the chest, will yet measure a different vital capacity, from some cause as yet unknown. There is no relation between the stature or weight, and the absolute cubic dimensions of the thorax. A stout man may have large lungs and a spare man small lungs; small lungs are *not* necessarily found in stout men. There is good reason to believe that in a healthy man, there is *no* relation between the extent of mucous surface in the lungs and the amount of aeration or oxidation of the blood. The circumference of the chest increases with the weight in relation of one inch for every 10lbs.

In measuring the chest with a common tape measure, allow a quarter of an inch for a flannel and a quarter for a shirt.

Mobility of the Chest.—The vital capacity and the range of thoracic movement appears to be in strict relation. In men of the same stature, a 40-inch chest with three inches mobility, must measure less vital capacity than a 40-inch chest with 4 inches mobility. Stout men have smaller thoracic mobility than thin men; the amount of aeretion of the blood is regulated by the mobility.

The mobility is *correctly* measured by the spirometer, it can also be estimated (less correctly) by a common tape measure. Note the minimum circumference of the chest after a forced expiration, then cause the chest to be expanded to its maximum and again measured, the difference is the "*Mobility*."

In healthy persons of ordinary weight and middle age of life, (by the tape measure,) the mobility averages three inches, seldom four inches. This observation is valuable and simply accomplished.

Effect of Weight.—The relation between the weight and the vital capacity as yet does not appear definite; yet when observations are more extended, this will be cleared up. In large numbers, to a certain extent, it is apparent, but probably it will never be a guide to determine the vital capacity in solitary cases, because it is difficult to tell a man's *proper* weight.

TABLE OF THE WEIGHT.

In relation to stature on 2648 healthy males of the middle period of life.

Exact stature in inches.	Weight in lbs.	Weight increased by 7 per cent.
61	120	128
62	126	135
63	133	142
64	139	149
65	142	152
66	145	155
67	148	158
68	155	166
69	162	173
70	169	181
71	174	186

According to the present data it may be said the weight (which increases with the height,) does not diminish the vital capacity until the weight exceeds, by 7 per cent., the above weights at each height, and then in the relation of one cubic inch per lb. for 35lbs.; beyond this, probably, it will be found to diminish in a geometrical relation.

For example, if the man of 61 inches weigh 120lbs., he may exceed this by 7 per cent.—8·4lbs. may be added, making 128lbs. (128·4) then the vital capacity may be expected to diminish. ($120 \times 7 = 840 \div 100 = 8{\cdot}4$lbs.) A full meal will diminish the vital capacity from 12 to 20 cubic inches.

Effect of Age.—Time affects the animal kingdom in a two-fold manner—bringing it to perfection and then deteriorating that perfection. From 15 to 35 the vital capacity increases, and from 35 to 65 it decreases nearly $1\frac{1}{2}$ cubic inches per year. Perhaps, generally, age need not be taken into account before 40 or 45, yet it is *considered correct for Insurance Offices* to take it into account from the age of 35.

Intercostal Muscles.—Every external intercostal muscular lamella can elevate the rib *above it, independently* of any other intercostal muscle. The eleven external intercostal lamellæ on either side, can each *independently* lift two ribs, so respiration can be carried on *without* the first or superior rib of necessity being fixed.

GENERAL REMARKS AND PRACTICAL DEDUUCTIONS.

Boerhaave says "scarcely any particle remained in the body which was not more or less concerned in the business of respiration;" therefore this great function must be extensively knit to our well-being. The spirometer is believed to be useful in measuring this function; it is a guage in a two-fold sense,—a measure for mobility, as well as a measure for capacity, because a man cannot breathe without moving. If disease affects the mobility of the body, the spirometer *must* measure this effect.

The discovery of the seat of disease demands the consideration of a number of circumstances—every observation is a link in the chain, leading one way or another, and that observation which can be measured and is capable of *definite* expression, will be found to weigh heavily in our diagnosis. All we know is gathered from physical observation, through the medium of our senses; physical alterations in the conditions and relations of parts, can only be determined by sight, touch and hearing; the more surely these are tested and definitely expressed, the more perfect is our comprehension of any change. No science is useful unless capable of this sure expression; the great epoch in chemistry was the atomic theory, founded on evidence, not involving hypothesis, an arbitrary measure is selected and a luminous explanation of the laws of combination of matter is made apparent. This definite language is *figures*—a language of relative powers. If a man breathe into the spirometer 200 cubic inches of air it is neither 199 nor 201. Two thousand men thus examined demonstrate that the vital capacity is under certain circumstances the same, and it may be proved that by a little training we can measure the most delicate deviation from this constant quantity.

From the mean of many observations in phthisis, in the early stage the vital capacity measured 149 cubic inches *instead* of 224; in the advanced stage, 83 *instead* of 220 cubic inches.

If we express a man's state in such language, we shall feel it beget a confidence pleasing in diagnosis. The physician to an insurance office is at the same time shielded against certain remarks from the actuary or board of directors, that great reproach of the art "its uncertainty."

An example of a book headed and filled up with cases:—

Comparison of Different Persons in Health and Disease.

Initials.	Vital capacity.	Power of Inspiration.	Power of Expiration.	Circumference of Chest.	Mobility of Chest.	Respirations per minute, sitting.	Pulse per minute, sitting.	Height.	Weight.	Age.	Remarks.
A.	240	3.20	5.50	38¼	3¼	20	80	5ft. 9in	12st 9lb	28	Wresder.
B.	300	3.50	5.30	41	3¼	20	83	6 1	13 8	21	Soldier, H. G.
C.	214	3.70	4.20	34	3	18	79	5 6	10 11	23	Thames Police.
D.	464	3.15	3.70	50	4	16	78	7 0	21 8	27	Giant.
E.	80	3.00	3.74	29	3	29	102	3 9⅜	4 7½	35	Dwarf.
F.	108	0.75	0.46	35¼	1¼	40	60	5 11	10 0	60	Phthisical.
G.	80	1.50	2.00	35	1	40	100	5 9	10 0	36	Ditto.
H.	260	0.50	1.30	34	3¼	21	64	5 7	10 1	29	Tympanum ruptured.
I.	222	0.50	1.00	34½	3	16	80	5 6	10 4	40	Hernia.
J.	186	0.70	0.80	36	1½	28	100	5 8	10 3	30	Incipient Phthisis.

Here is expressed as an illustration, this method of observation upon cases actually examined.

The eye at once will perceive a great difference in these ten persons.

The first three are healthy cases; the vital capacity corresponds with the height according to the rule laid down. The inspiratory and expiratory powers are not only considerable, but bear their proper relation to each other. The mobility of the chest is also natural, and the weights are indicative of health. Therefore it may safely be said, these three men have healthy lungs, or, at least, permeable to air, throughout their entire extent. Their respiratory power is indicative of great physical strength.

The fourth case (D.) has a remarkable vital capacity;

but his height is seven feet. The respiratory power of this man is below par, particularly his expiratory power, which indicates that there is some cause existing which prevents his expiratory muscles acting with healthy vigour.

The next case, though measuring a vital capacity of 80 cubic inches, is of short stature, (3 ft. 9¾ in.) This little man's respiratory power appears better than the case of D., though his pulse and respiration per minute is certainly objectionable. He is now dead.

F. and G. are examples of persons labouring under phthisis. The stature shews that their vital capacity is *very* much below the natural standard: instead of 108 it should have been 254, and, instead of 80, 238 cubic inches. Their respiratory *power*s are also much too low—the thoracic mobility two-thirds below the standard. All this disturbance is the effect of serious disease; the number of respirations and pulse are out of proportion.

In casting the eye along the line of figures in the case of H., the striking part is the respiratory power, which is so deficient, while every other observation looks healthy; this was a case of rupture of the membrani tympani. When the man closed his ears, his respiratory power was manifested as nearly three times stronger.

In the case of I., the respiratory power is deficient from hernia being present.

The last case is phthisis in an *early* stage: the measures here are sufficiently marked to excite attention. In one case the tubercular matter was not equal to one cubic inch, yet the diminution in the quantity of expired air was 47 cubic inches.

The most interesting case followed throughout, from the commencement to the termination, is that of Freeman, the "*American Giant.*" This man came over to England in 1842, and, in November of that year, trained for a prize fight; I examined him immediately before his *professional engagement*, when he might be considered in the "best condition." His powers were as follows:—Vital capacity, 434 cubic inches; height, 6 ft. 11¼ in.; weight, 19 st. 5 lb.; circumference of his chest, 47 inches; inspiratory power, 5.0 inches; expiratory power, 6.5 inches. In November, 1844, exactly two years afterwards, he came to town in ill health. I then examined him in the same way as before, twenty times at various intervals, during which his vital capacity varied from 390 to 340, and the mean of all the observations was 344 cubic inches, a decrease of 90, or more than 20 per cent.; his respiratory power had decreased one fifth, and his weight two stone. At this time I took him to two physicians well skilled in auscultation, and they *both affirmed* that they could *not detect* any organic disease. After January, 1845, I lost sight of Freeman, and, in the October following, I was kindly favoured with the following account of him from Mr. Paul, Surgeon to the County Hospital, Winchester:—

"Freeman was admitted into this hospital on the 8th of October, in an extreme state of debility and exhaustion; he was reduced almost to a skeleton, complained of cough, and was expectorating pus in large quantities. Percussion on the anterior part of the chest *under the clavicles* gave on the right side a very dull sound, on the left one much clearer, but still I think less resonant than natural. I made but one attempt at auscultation, but could come to no conclusion, from a rather singular reason,—the ribs were so large, the intercostal spaces so wide, and so sunk in from the extreme state of emaciation to which Freeman was reduced, that I could not find a level space large enough to receive the end of the stethoscope,—could not, in short, bring its whole surface into contact with the chest. Freeman's great debility, and the clearness of the diagnosis from other sources, prevented my repeating the attempt. Freeman, after death, measured 6 ft. 7½ in., and weighed 10st. 11lb. On opening the chest, the lungs on both sides were found adhering by their apices to the superior boundaries of the thorax, and studded throughout their substance with tubercles. The tubercles on the whole were much less numerous in the right lung than in the left; both lungs were nearly healthy at their base; the tubercular matter gradually increased in quantity towards their inner parts, and the apices of both lungs were almost completely occupied by large cavities partly filled with pus, and capable of containing two or three ounces of fluid each. The heart was remarkably small. The rest of the viscera appeared healthy."

It is very remarkable to see that Freeman lost so much weight; in his prime he never appeared stout, but strong and muscular. I have been informed, when he first came to England, his weight was 22 stone; he died 10 stone. His natural height was nearly 7 feet, and he died 6 ft. 7½ in. The spirometer was useful to me in this case, by indicating the commencement of the disease which ultimately caused his death, and that BEFORE THE USUAL MEANS AVAILED.

SHEFFIELD MEDICAL SOCIETY.

Sixth Session, Eleventh Meeting, Feb. 18th, 1847.

The President, Mr. TURTON, in the chair.

DISEASED BONE.

Mr. Thomas exhibited the leg of a female, aged 22, a prostitute, which he had removed in the morning. There was a large and extremely painful ulcer, together with considerable thickening of the periosteum and enlargement of the bone. The æther was used, and produced insensibility in rather less than two minutes and a half. In consequence of great retraction there was difficulty in securing the posterior tibial artery, and the æther was inhaled a second time. During the operation there was some moaning and screaming, but she does not know anything about the operation.

Mr. Thomas also exhibited the blood drawn from a moderately sized opening in the arm of a female aged 29, in the eighth month of pregnancy, for the relief of pneumonia. The coagulum presented the buffed appearance in *every* part.

Dr. Branson laid on the table "Dupuytren, on the Injuries and Diseases of Bones," the new volume of the Sydenham Society.

FIBROUS TUMOUR OF THE DURA MATER.

Dr. Branson exhibited a portion of dura mater from which a tumour, about the size of a small pullet's egg, grew, presented by Mr. Martin to the museum of the Infirmary. The patient was an elderly gentleman. When first seen by Mr. Martin, he was suffering from paralysis agitans of long duration, and extensive sloughing of the hips and sacrum. He had suffered from one or more convulsive attacks, and his habits and disposition had been materially affected by the disease. There was no loss of motion on the opposite side of the body to that on which the tumour was found until a few days previous to death. On inspection *post mortem* the tumour was found adherent to the dura mater, pressing upon the right middle lobe of the cerebrum towards its anterior and lateral part. The substance of the brain in its immediate neighbourhood was in a state of ramollissement. The pia mater beneath the tumour was absorbed, and that surrounding the part much injected. The tumour was of a fibrous nature, which was shown in a microscopical drawing made by Dr. Branson.

Mr. Hunter exhibited a scirrhous breast from a female aged 38, in the centre of which was commencing ulceration, but no retraction of the nipple. The æther had been used in the operation.

INSUFFICIENCY OF THE AORTIC VALVES; DISEASED HEART: BRIGHT'S DISEASE.

Mr. Law exhibited the heart and kidneys of a scissor-grinder, who had suffered most probably from fever prior to admission into the Infirmary. When admitted his symptoms were,—voracious appetite, severe cough, general anasarca, increased space of dulness in the præcordial region, and a loud *bruit de soufflet* accompanying both beats of the heart, heard most distinctly near the cartilage of the fourth rib, and having with the first beat a somewhat musical character. It was obvious that both obstructive and regurgitant disease of the aortic valves existed, with hypertrophy and dilatation of the left ventricle. On inspection *post mortem* a large deposit was found on the ventricular surface of the valve, which it is obvious would offer considerable obstruction to the passage of the blood from the ventricle, and it accounts for the musical character of the bruit which accompanied the first beat, and is precisely the condition of valve which gives rise to eccentric hypertrophy and dilatation of the left ventricle. The insufficiency of the valve was proved by experiment, water passing readily out of the artery into the ventricle. The kidneys were good specimens of Bright's disease, and were most probably, rather than the heart, the cause of the anasarca. The urine was light-coloured, but did not coagulate either with heat, nitric acid, or bichloride of mercury.

Mr. Jackson exhibited Avery's instrument for the inspection of internal cavities.

Dr. de Bartolomé read a paper "On Pericarditis."*

* An abstract of this paper will be given in the next number of the Journal.

Twelfth Meeting. March 4th, 1847.

The PRESIDENT in the Chair.

Mr. Porter, through the kindness of Mr. H. Taylor, V.S., exhibited an apparatus for the administration of the vapour of æther to horses, and explained its construction.

SCIRRHOUS MAMMA.

Mr. H. Jackson then exhibited a scirrhous breast, which he had that day removed from a patient, aged 44, a married woman, who had borne four children, and in whom menstruation still continued at the regular periods. The patient had enjoyed good health, and according to her account, it was only seven months ago that she perceived a slight tumour immediately below the nipple of the right breast. This existed for two months, when it became painful, and the intensity of pain has increased, and also the duration, up to the period of admission into the Infirmary. She could assign no cause for it. The tumour was completely free; no enlarged axillary gland; and, with one important exception, there was every indication of success in the operation. The skin was of a dusky yellowish colour, as after jaundice. The operation was performed, the æther being used. It did not produce the indications recommended to be obtained for twelve minutes, and then there was no upturning of the eye, but rather a fixed state, together with an evident filling of the vessels of the cheeks. Under these circumstances the operation was proceeded with, and on the first incision, the patient uttered screams, and afterwards moans. During the progress of the operation, she sank into a state of insensibility, from which she soon revived. She was not conscious of having uttered any expression of pain whatever, not having felt any, and was not aware of the first incision being made, the first thing which she recollects being an expression made use of by Mr. Thomas, during the securing of the vessels. In about an hour after, when the wound was dressed, she complained of great soreness and pain on the passing of the sutures. The difference between arterial and venous blood was very evident. The scirrhus appeared to have originated just below the nipple, which was retracted, and was about the size of a small orange, and exceedingly firm.

Taking into account the fact of the patient being insensible to pain, although apparently awake to everything when the operation was commenced, Mr. Jackson suggested that it might not be impossible, by repeated trials and careful observation, to establish the point at which all the useful purposes of the æther vapour might be procured, so far as inducing insensibility to pain, without arriving at the apoplectic appearance recommended to be attained previous to the commencement of the operation.

General Retrospect.

PRACTICAL MEDICINE.

TETANUS SUCCESSFULLY TREATED BY TOBACCO INTERNALLY.

Mr. Pridie, of Stockton-on-Tees, reports the following case:—A female, aged 44, injured her arm by falling upon a nail. On examination, a lacerated wound was found near the elbow, but it gave rise to no anxiety until the end of a week, when the granulations were observed to look flabby. Sulphate of copper lotion was applied, and the bowels were freely acted upon by colocynth and elaterium. After this time, considerable difficulty was experienced with the bowels, and on the 14th day after the injury, the patient began to complain of pain in the head and back, with trismus, and rigidity of the legs and left upper extremity. The heart's action was slow and languid, and convulsion followed attempts to swallow. As the tetanic symptoms increased, it was determined to try the tobacco, and accordingly half-an-ounce of an infusion of thirty grains to nine ounces, was given every one, two, or three hours, according to its effect. The bowels acted after the third dose, and the pain appeared less during the paroxysm. The medicine was continued, and on the next day produced great nausea and vomiting, after which the paroxysms abated in frequency. The same plan was persevered in, with the addition of enemata of tobacco, for five days, when opium was added. The tobacco was finally omitted on the eighth day.—*Monthly Journal of Medical Science*, March, 1847.

[This case appears at first sight to afford strong evidence in favour of the remedy employed, but it must be recollected, that, as has been noticed as long ago as the days of Hippocrates, cases of tetanus which survive the fourth day, and become chronic, frequently if not generally do well; we are therefore here at a loss how much to attribute to the tobacco, and how much to the greatly neglected agency of the *vis medicatrix*.]

GALVANISM IN APHONIA.

The following is the description of one of the earliest modes of applying galvanic action to the treatment of disease, and on account of the long continuance of its effects, is thought by Mr. Donovan to hold out considerable advantages:—In the case of a young lady, affected four years with hoarseness, and more or less complete aphonia, blisters, mercurials, &c., had been used without any relief. Her physician, Dr. Grapengiesser, then thought of increasing the action of blisters by galvanism, and accordingly, having vesicated each side of the larynx to the size of a shilling, he covered the excoriated spots on one side with a zinc plate, to which a wire of the same metal was attached, and on the other with a piece of silver. As soon as he brought the two plates in contact, a burning sensation at those spots arose, and the larynx heaved up and down convulsively, with loud sobbing. On alternately breaking and re-joining the contact, these motions became so violent, as to be almost insupportable. After this process had been continued for a quarter of an hour, a watery humour began to run from the excoriated surfaces. The apparatus was removed, and towards evening she began to speak more audibly and the improvement continued next day, but was lost again on the fourth or fifth day. The process was then repeated, with the same results, and the apparatus was left on all night, with the effect of permanently restoring the voice.—*Dublin Quarterly Journal*, Febr. 1847.

EFFECT OF HYDROPATHY ON THE BLOOD.

Lest there should be any amongst us, which I trust there is not, with a tendency to desert legitimate medicine for the crooked ways of water-quackery, we may mention, as a caution, that a German physician, M. Albert, who has had ample opportunities of witnessing the operation of the water-cure, has remarked that persons who have pursued the system uninterruptedly for two or three months, are apt to acquire a habit of body not dissimilar to that of scurvy. The pulse becomes accelerated, soft, and feeble. The patient is subject to palpitations and a continual feeling of lassitude, and eventually suffers from spongy gums and aphthous ulcerations of the interior of the lips and cheeks. From these symptoms M. Albert concludes that the immoderate use of water has a tendency to impoverish the blood.—*Dr. Ranking's Retrospective Address.*

TREATMENT OF APHTHÆ.

Professor Lippich, of Padua, employs, with success, the sulphuric acid against aphthæ, and in syphilitic mercurial stomatitis, when the mucous membrane of the mouth and lips is covered with ulcerations, which render deglutition difficult. He uses the following formula:—R. White honey, 30 grammes; sulphuric acid, 2 grammes. Mix, and make a liniment. In severe cases the proportion of the sulphuric acid may be increased to eight grammes to the same quantity of honey. The ulcerated surfaces are to be frequently touched slightly with this liniment by means of a soft pencil.—*Gazette Méd.* and *Dublin Med. Press.*

Dr. Coudray reports several cases of aphthæ in which the topical application of pure muriatic acid was followed by complete success. In many cases, when the exudation did not occur in thick laminæ, and when it occupied the tongue and lips only partially, it sufficed to use the acid diluted by an equal proportion of water, or two parts of the latter to one of the former. But whenever the pseudo-membranous material was thick, resisting, and yellowish, and the child refused the breast, he had recourse to the pure acid, one or two applications of which caused the separation of the false membranes. Its use, he states, is attended with very little pain, and infants who had been unable to take the breast for several days before, became capable of sucking in a few hours afterwards.

Bretonneau, many years ago, extolled the use of muriatic acid in this form of stomatitis; and again, last year, Trousseau and Delpech called attention to the great efficacy of the *fuming* acid, as one of the most powerful modifying remedies in severe aphthæ. Dr. Coudray, therefore, proposes nothing new. His cases,

it may be also mentioned, belong to the symptomatic species, which supervenes generally in cachectic children, in whom the cure of the stomatitis itself is of much less importance than when it is idiopathic. In the latter instance, it is usually mild, except when epidemic, in which case the most energetic local treatment is of little avail.—*Dublin Quarterly Journal* and *Lancet*.

EXTRACT OF RHATANY AND VAPOUR-BATHS IN ALBUMINURIA.

A man, aged thirty-one, mechanician, was admitted into the Hôpital of La Charité, on the 28th of December, 1846. Fifteen years ago the disease began by a considerable anasarcous swelling of the feet, which lasted three or four years. Erysipelas of the legs appeared, and was dispelled after six weeks, leaving the œdematous swelling by which it had been preceded. This state of things continued, and five years ago the patient entered M. Rayer's ward, where he was treated by aromatic fumigations, iodide of potassium, and warm baths. Under the influence of these measures the dropsy yielded, but the albuminuria persisted. At the end of a week the œdema showed itself again, and the treatment having been instituted anew, a considerable improvement was obtained. Since that period the patient enjoyed uninterrupted health, but the symptoms returned in the beginning of December, 1846, without any apparent cause. The legs and scrotum were considerably infiltrated, and ascites was present; a general sensation of lassitude, and pain in one, sometimes both sides of the abdomen, were complained of; the bowels were confined, the appetite preserved, and frequent paroxysms of cough were observed; the urine was pale, slightly acid, abundant, and contained a large quantity of albumen —coagulable by heat and nitric acid. Every day half a drachm of extract of rhatany was exhibited in a mixture; vapour baths were ordered, and low diet. Under the influence of this treatment, a gradual amelioration occurred, and on the 10th of January the urine contained no more albumen. On the 12th the patient left the hospital, if not completely cured of his renal disease, at least cured of the symptoms which he had laboured under, and which are generally looked upon as characteristic of granular disease of the kidney.—*Medical Times*.

ERGOT OF RYE IN RETENTION OF URINE.

In a recent number of the *Lancet* Dr. Lanyon relates the case of an old man, in whom the catheter was passed several times a-day, on account of retention of urine, but who subsequently found speedy relief from the use of ergot. Thirty grains of this drug were infused in three ounces of boiling water, and of the cold infusion, the patient was ordered to take a third part every six hours. After the third dose, he passed about half a pint of urine without impediment, and the natural function was restored. The case appears to have been one of spasmodic stricture, and the reporter regards the *modus operandi* of the medicine, to have been anti-spasmodic.

[The ergot has frequently been used in cases of retention from loss of muscular tone of the vesical parietes, which are, we believe, the chief cases in which it is likely to prove serviceable.]

SURGERY.

TREATMENT OF BURNS WITH AMMONIA.

M. Guerard has employed a concentrated solution of caustic ammonia in burns for more than 20 years. He states that when he has burned his own fingers in chemical or other experiments, he has dipped them in the solution, or covered the injured part with a compress wetted with it, as the case may be. The application is said speedily to remove the pain, but it should be continued for half an hour to produce a lasting effect; after this the burn requires no dressing. *Annales de Thérapeutique*, 1847.

TREATMENT OF ULCERS BY EXTERNAL HEAT.

Mr. Barnes, of Notting Hill, states that he has repeatedly witnessed the beneficial effects of external heat in procuring the cicatrization of unhealthy ulcers, such as those which are left after the opening of buboes. The heat is applied by holding a red hot cauterizing iron at such a distance above the sore as to communicate a sensation of agreeable warmth. In proportion as the iron cools it is held closer to the wound. He states that he believes this plan to be peculiar to the practice of Malgaigne. The first effect is a cleaner appearance of the sore, then a shining white pellicle spreads over its surface, and cicatrization frequently commences within twelve hours. In two cases it was complete in eighteen hours.—*Lancet*, January 23, 1847.

ON THE TREATMENT OF ANEURISM BY COMPRESSION.

Dr. Bellingham concludes an interesting paper with the annexed summary of some of the most material points bearing upon this method of treatment:—

1. The arteries to which compression is applicable being far more frequently the subject of aneurism than those to which it is inapplicable, compression is calculated to supersede the ligature in the great majority of cases.

2. The cure of aneurism by compression upon the artery between the aneurismal sac and the heart, according to the rules laid down here, is accomplished by the gradual deposition of the fibrin of the blood in the sac, until both the latter and the artery at the part are completely filled. The process is in fact exactly similar to that by which nature effects a spontaneous cure of aneurism.

3. Such an amount of pressure as would cause inflammation and adhesion between the opposite sides of the artery at the point compressed is never required.

4. The pressure should not be so great as to interrupt the circulation in the artery at the point compressed; an essential agent in the cure being that a current of blood should pass through the sac.

5. Compression by means of two or more instruments, one of which is alternately relaxed, is much more effectual than by any single instrument, and in many instances the pressure can be maintained by the patient himself.

6. The treatment of aneurism by compression does

not involve the slightest risk to the patient, and if persevered in cannot fail of effecting a cure.

7. A cure of aneurism effected by compression, according to the rules laid down here, must necessarily be permanent; and in every case in which a cure has been accomplished, the patients have remained well subsequently.

8. The femoral artery remains pervious after the cure at the point at which the pressure had been applied, and no morbid change of any kind is to be detected in either the artery or vein at the side of the compression.

9. When a cure is effected by compression, the vessel is obliterated only at the seat of the aneurism, and the artery at this part is eventually converted into an impervious ligamentous band.

10. Compression effects the cure of aneurism by more simple and safer means than the ligature, while it is applicable to a number of cases in which the operation is contra-indicated or inadmissible.

11. Compression is not necessarily a more tedious or more painful method of treating aneurism than the ligature, while it is much more certain, more likely to be permanent, and is free from all danger.

12. Compression, according to the rules laid down here, has little analogy with the old method which went by this name; and in fact has no greater resemblance to it than the Hunterian operation had to the operation for aneurism which it superseded.—*Dublin Medical Press*, Jan. 20, 1847.

HERNIA OF THE FORAMEN OVALE.

M. Roeser states that hernia of the foramen ovale is a rare affection, and is seldom discovered until after death, unless it is very large. In a case which occurred in his practice six years before, he had himself overlooked the accident. In the present instance he was more fortunate. The patient was a female, aged 30, mother of one child, two years old, and of another aged ten. For six years she had suffered at long intervals from acute pain in the stomach, which arose without apparent cause, and spread over the abdomen, subsiding after the occurrence of vomiting. On February 16th, 1846, she had an attack of the usual pain, but this time it did not subside, although vomiting had occurred as usual. Next day she was bled, and castor oil was exhibited, without effect, and morphia was given. The author saw her on the succeeding day; there had been vomiting in the night without mitigation of the abdominal pains, and there was now an acute burning sensation at the pit of the stomach; the urine had been scanty, and entirely suppressed for twelve hours; she could not lie on either side; when placed in the sitting posture she complained of an acute pain in the bowels; the belly was swollen, and tympanitic, and presented inequalities arising from distended portions of intestine; pulse frequent; no appearance of hernia at the usual apertures. Dr. Roeser was led to examine the pectineal region, when he remarked a tenderness over the left foramen ovale, which was not observed on the opposite side. On a more careful examination, he found at this spot a tumour, the size of a nut, of an elastic feel, and painful. This tumour might have been mistaken for a gland, but that it was more tense, smooth, and less pasty, and escaped under the fingers, while pressure caused an inward pain, which extended to the epigastrium. These symptoms indicated hernia of the foramen ovale. After the taxis had been persevered in for half an hour, the hernia was reduced; there was immediate relief, and in half an hour the bowels were evacuated. The narrator of the case concludes by urging the necessity of examining all the outlets, in cases of colicky pains, and the so-called neuroses of the abdomen.—*Gazette Médicale*, Fev. 6, and *Monthly Journ. of Med. Science*, March, 1847.

ADVANTAGES OF THE FLAP-OPERATION.

In the thigh and leg, after amputation, it not uncommonly happens that everything looks well for a few days, but that then some matter forms, or the limb jerks, or is hot, or the skin gets just a little tight at one part over the bone. In these cases the flap-operation succeeds better than the circular, for it rarely happens that the skin of the circular operation can be got well forward again after it has once begun to retract or become tight, whilst the mass of muscle and soft parts of a flap can often be brought down again after they have contracted very considerably. In the thigh, puncture of the artery, above its division, is readily avoided in the flap-operation, and cannot well be done in the circular. In the leg, the artery may readily be punctured, in passing the knife behind the limb, and wounded above its division; still this is no real objection to the flap-operation below the knee, as the same accident may happen from the use of the catlin. The rapidity of the flap-operation, compared with the circular, is some advantage, but the whole operation is not necessarily shorter, for the number of arteries to be tied in the former case is generally greater than in the latter. During the last few years, the double flap-operation has been performed upon a large number of patients at St. Bartholomew's, by Mr. Stanley, and with the best result. In many of these cases at their termination, the full soft condition of the face of the stump, the complete depression of the bone in the line of the union of the flaps, or beneath the front flap of the thigh, have been most marked; whilst the effects of inflammation, in rendering the stump tense, have been very much less than where the same accident occurred after the circular operation.—*Ormerod's Clinical Observations*, p. 131.

OPHTHALMIA NEO-NATORUM.

Dr. Eschrish states, that in the ophthalmia of new-born infants, he has always effected a perfect cure in a shorter time than usual, (one week,) by surrounding the eye or eyes with a thick layer of mercurial ointment. We should be sorry to trust a severe case of this disease to this remedy, and the Munich physician acknowledges in his paper, that in addition to the mercurial inunction, he uses frequent injections of tepid-water, and when the swelling and discharge have lessened he employs a weak caustic solution. Professor Von Ammon recommends a lotion of six grains of extract of belladonna and ten drops of lime-water to four ounces of distilled water; with this the eyes are to be

steeped every half hour, and in the interim, a bandage wet with the solution, is to be applied over the eyes. His object in using the belladonna is to allay the spasm of the eyelids, and by facilitating the matter to allay the swelling of the conjunctiva and cornea. This certainly is not heroic practice, and few practioners in this country would trust a patient to it alone. Having constantly remarked an extensive state of ulceration in the conjunctiva of the upper lid in the severe forms of this disease, I now generally evert the lid to examine its inner surface as soon as a case presents itself, and we have several times succeeded in cutting short the disease by at once applying a strong solution of nitrate of silver to this part alone. We beg to call the attention of ophthalmic surgeons to this subject.—*Report on the Progress of Ophthalmic Surgery*, in *Dublin Quarterly Journal*, Febr., 1847.

TOTAL ABSTINENCE AND "MEDICAL TESTIMONY."

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I beg to call the attention of your readers to a document which has been signed by more than a thousand medical practitioners of Great Britain, and which is now being extensively circulated in the publications of the different (so called) Temperance Societies. The document is entitled "Medical Testimony," and consists of a declaration of opinion in favor of "total and universal abstinence from alcoholic liquors and intoxicating beverages," on the ground of their being unfavourable to *health*, and for other reasons.

Mr. Dunlop, who has obtained the signatures to this document, brings them before the public with no little natural gratulation. This gentleman is anxious to obtain the signatures of a larger proportion of the 20,000 medical practitioners of Great Britain; and urges upon the advocates of total abstinence, "to take strenuous measures to have the certificate signed as extensively as possible," in their respective neighbourhoods. When a greater number of signatures has been obtained, Mr. Dunlop expects to see changed, "the unscientific principles and hazardous dogmata on the use of alcoholic liquors," which he states, "too much regulate and characterize the practice of the bulk of our medical world."

It is unnecessary to insert the certificate itself. It is more cautiously worded than some others which have been submitted to myself, for the purpose of obtaining my signature; but still I must regard several of the assertions which it contains as unproved, and consequently rash and dangerous. Many of the distinguished physicians and surgeons, who have signed the document, have, I doubt not, done so deliberately and advisedly: some of them I know to be themselves consistent abstainers from all alcoholic and fermented liquors; and, however I may dissent from their opinion, it nevertheless claims and secures my respect. With others, and, perhaps, the majority, the case has been far different. The act has not been, I think, a deliberate one; the signature has been given with little or no consideration of the evidence on which such propositions, regarded as scientific truths, may be supposed to rest, or of their legitimate consequences, if true. An easy good nature, hardly excusable, has caused the signature of many to be given; and the excellence of the object has probably still oftener led the subscriber to overlook the doubtful character of the means. In some cases I know that the authority of names has been strongly urged against the deliberate judgment of the persons applied to. In other cases, perhaps not a few, it has been urged that signing the document did not in any way pledge the individual conduct of the person signing, and, if I mistake not, such a consideration was actually printed on the form of declaration which was sent for my own signature from a Medical Temperance Society, in February of last year, accompanied by the following note:—

"Dear Sir,—Your signature to the enclosed certificate would be very highly prized by all who are interested in the advancement of the important and wide-spreading principle of true temperance. *An early* reply would much oblige, yours respectfully, ——— ———."

The following is a copy of the certificate which was stated to be "in progress of signature throughout the United Kingdom, and has already been subscribed to by at least 174 medical men:"

"We are of opinion that there is *no* principle of strength or nourishment for the human frame in ALCOHOL, as is commonly supposed, or generally in drinks of which it forms a part, such as ardent spirits, fermented wines, cider, ale, beer, porter, and others. That any trifling portion of nourishment contained in the last three, is greatly exceeded by that in barley-water, porridge, or gruel, made from an equal quantity of grain. That the use of ALCOHOLIC beverages generates ultimate weakness instead of strength, and tends to cause subsequent debility in the frame. That the above-mentioned intoxicating fluids are in no way necessary to persons in ordinary health; nor are they required for any particular constitution. That the daily or habitual use of *any portion* of them is prejudicial to health. That the excitement or cordial feeling they create is mere *stimulation*, which departs in a short time, and is unproductive of any element of real strength; and that, contrary to ordinary opinion, the health and average comfort of the *nation* would be greatly promoted by their entire disuse as *beverages*."

I think that members of the medical profession should pause before they commit themselves to any such opinions as these, for the following reasons:—

1st. Abstinence and temperance are two entirely distinct things: the latter is a virtue; the former, as regards lawful things, is no virtue at all.

2nd. The assertion that the daily or habitual use of any portion of wine or other fermented liquors is prejudicial to health, appears to be altogether at variance with ordinary observation and experience.

3rd. Too little of the vital chemistry of the human body is known for us to assert "that there is *no* principle of strength or nourishment for the human frame in alcohol, or in drinks of which it forms a part."

In the former editions of his "Animal Chemistry," Liebig reckons wine, beer, and spirits, amongst those non-azotized ingredients of our food, which act as elements of respiration, and are expended in the production of

animal heat, and in protecting the organism from the action of the atmospheric oxygen.* (pp. 53, 96.) I have not yet seen the third edition of this well-known work, but from a review† of it, I find that the agency of alcohol, as a respiratory element of food, is illustrated by the following anecdote:—"In England, servants receive daily a certain amount of beer, or in the case of total abstinence, its equivalent in money. A friend informs me, that in a certain household it was observed that from the day on which the servants ceased to receive beer from their masters, the consumption of bread increased in a ratio corresponding to the diminution of beer; so that the beer was twice paid for, once in money, and the second time in the form of an equivalent of another kind of food, yielding the same amount of carbon and hydrogen." (p. 98.)

The reviewer, evidently adopting Liebig's own views, further observes:—"The alcohol of fermented liquors plays the same part in the body of man as the non-nitrogenized constituents of his food; for although its elements do not of themselves possess, at the temperature of the body, the property of combining with oxygen, yet brought into contact with other bodies, during their eremacausis or absorption of oxygen, which are always present in the body, it acquires the property in a higher degree than fat, or other non-nitrogenized substance."

The celebrated chemist, Mitscherlich, has indeed come to the conclusion that alcohol is actually formed in the system from the sugar of our ordinary food, and that subjected to a slow combination in the lungs, it becomes the source of animal heat. I mention this, not as an established truth, but merely to shew that the doctrines of animal chemistry, at the present day, do not confirm the propositions as to the necessarily injurious effects of fermented liquors.

I am not indifferent to the magnitude of the evils connected with intemperance, and I consider that the physician and surgeon are bound to exert their legitimate influence in diminishing the source of so much disease, misery, and death. Let them, however, hesitate before they give their sanction to opinions, hastily taken up, which are not supported by ordinary experience, and not illustrated by their own example. Let them pause ere they bring their character as men of science into question by assertions which are not borne out by well-ascertained facts in physiology and chemistry.

Modern teetotallism is a species of Quixotism, which seems to me to be only redeemed from the charge of absurdity by the reality and extent of the evil with which it attempts to cope. Good has doubtless been effected by it, as it has been by various other popular movements, when directed against evils of great magnitude, in spite of the exaggerated views and ill-directed means with which they have been accompanied and prosecuted. The end, however, does not justify the means; and men of reflecting minds will reject, as more than doubtful, all efforts for good which seek their support in ill-founded views and ill-judged exertions. It is not, however, to be supposed, that fermented liquors which have been used by our species in nearly all climes, and as long as the history of the race has extended, will be disused, on any large scale, or for any long continued period. Let us abolish, if we can, the use of distilled alcohol; let it be found only in the shop of the druggist, and in the warehouse of the varnish maker; and let a crusade be entered only against "excess of wine." Deprive us not, however, altogether of that barley wine, the beer of these more northern countries, with which the poor man has been wont to sweeten his homely meal, after the labours of the day. In warmer latitudes, and for the more affluent, do not deny the temperate and right use of the wine of the grape, intended, as the psalmist tells us, "to make glad the heart of man," and which was used by the founder of our religion, habitually, as well as on the most solemn occasions. I would add, in the words of a recent writer,* "Let moderation be known in all things, and despise not the wisdom of Solomon, who tells us that wine has its uses. Strong drink is more suitable than cold slops for a man with a flagging pulse and sinking heart. The maker of man designed him to enjoy life under a wise use of all that is good: obedience to Divine law allows of no extremes, and temperance implies *in mediis tutissimus* —an equal danger both from abstinence and excess."

I am, Sir,

Yours faithfully,

O

* Moore's "Relation of the Body to the Mind."

* This distinguished chemist farther states, that after alcohol has been taken into the stomach, according to all the observations hitherto made, neither the expired air, nor the perspiration, nor the urine, contains any trace of alcohol, and that there can be no doubt that the elements of alcohol combine with oxygen in the body, that its carbon and hydrogen are given off as carbonic acid and water. p. 239.

† "Med. Chirurg. Review," Jan., 1847

CASE OF POISONING BY THE TINCTURA FERRI SESQUICHLORIDI.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Will you be good enough in your next number to correct a mistake which occurred in the report of the case under the above title in your last. The quantity of the tincture of the muriate of iron swallowed was *one ounce and a half*, and not "a drachm and a half," as erroneously stated. There was no irritation in the urinary system, as in the case mentioned by Mr Taylor, but perhaps there would have been if the smaller doses had been taken, and retained for any length of time in the stomach or bowels. As the mistake is an important one, you would oblige me by inserting this note, or at least by correcting it.

I am, Sir,

Faithfully yours,

THOMAS EDWARD AMYOT.

Diss, Norfolk, April 9, 1847.

ANNOUNCEMENT EXTRAORDINARY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I beg to direct your attention to the following advertisement which appeared in the *Liverpool Mercury* for Friday, April 2nd. It surely behoves the College authorities to notice the mode in which some of its members fulfil the obligations imposed on them.

Your obedient servant,

A MEMBER OF THE ASSOCIATION.

Liverpool, April 6th.

"College of Medicine and Surgery for treating patients on the principles so long and successfully practised at Whitworth, and Oldfield Lane, Manchester, conducted by Mr. ———, M.R.C.S., and L.A.C., prizeman of St. Bartholomew's Hospital, London, in the Session 1843-44, &c., &c., who may be consulted on all cases appertaining to his profession daily from nine to three, and from six to nine, and on Sundays from ten to two, at the College, 46, ————, near the corner of ———— Street. An assistant in continual attendance for any cases of emergency."

[We suppress the name and address, as we have no wish to contribute towards the object which this prizeman of St. Bartholomew's would seem to have in view, but they are at the service of either of the corporate bodies to which the advertiser professes to belong.—Ed.]

Medical Intelligence.

MEDICAL REGISTRATION BILL.

HOUSE OF COMMONS.

[*From the "Notices of Motions" which now stand on the "Order Book" of the House.*]

"On Tuesday, April 20th:—

Mr. Wakley to move for leave to bring in a Bill to provide for the Registration of legally-qualified practitioners in medicine, and to amend the law relating to the Practice of Medicine in Great Britain and Ireland."—*Lancet.*

MEDICAL APPOINTMENTS.

Dr. Arthur Tawke has been elected Physician to the Norfolk and Norwich Hospital, in the room of Dr. Lubbock, deceased. Dr. Ranking, late of Bury St. Edmunds, who is now resident in Norwich, was also a candidate, but retired from the contest, as being too late in the field.

Dr. Francis Henry Woodforde has been appointed one of the Physicians to the Taunton and Somerset Hospital, in the room of Dr. Catlett, resigned.

Dr. A. B. Garrod and Dr. E. A. Parkes have been elected Assistant-Physicians, and Mr. J. P. Potter, Assistant-Surgeon, to University College Hospital.

Dr. A. L. Brownless, of Charterhouse Square, has been elected Physician to the Metropolitan Dispensary, Fore Street.

Dr. Henry Davies has been elected Consulting Physician to the British Lying-in-Hospital. Dr Robert Lee has been elected Physician in Ordinary, and Mr. Benjamin Brookes Principal Surgeon to the same Institution.

J. W. Harris, Esq., has been elected Surgeon to the Exeter Dispensary, in the room of Mr. Pridham, resigned.

QUEEN'S COLLEGE, BIRMINGHAM.

The first sessional examination of the students in the department of general literature and science, was held on Saturday, April 11th, and on Monday, April 13th, 1847, when the following list was returned by the examiners:—

Classics.—1st. CLASS.—Fryer, Coleford; Wall, Stratford-on-Avon; Yarwood, Birmingham; Edney, Craig, Kilmarnock.

2nd CLASS.—Seven.

Mathematics.—1st. CLASS.—Wall, Fryer, Yarwood.

2nd. CLASS.—Edney; Rice, Stratford-on-Avon; Rose, Madeley; Wilkinson, Northleach; A. T. Davies, Birmingham.

3rd. CLASS.—Three.

Chemistry.—1st. CLASS.—Edney, Fryer, Wall.

2nd. CLASS.—Five.

Lyttelton, M.A.,
James Thomas, Law, M.A.,
W. M. Lawson, M.A.,
G. Richards, B.A.,
G. Taylor, B.A.,
George Shaw.
} *Examiners.*

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members, April 9th, 1847:—E. P. Wilkins; E. Lund; C. J. Gibb; R. J. Brackley; C. Mackechnie; W. E. Hayman; R. B. Painter; J. H. Prosser; W. B. Gill.

Admitted April 12th:—J. S. Ayerst; G. N. Ediss; W. P. Harrison; T. Edis; G. B. Barrow; F. Robinson; J. H. Richardson; O. Pemberton; F. Acret; E. C. Cottingham; R. J. Hansard.

The following gentlemen were admitted Fellows on Wednesday, April 14th:—Francis Toulmin, Esq., Clapton; Frederick George Reed, Esq., Hertford.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates on Thursday, April 8th:—Frederick Mason, Bath; Charles Astley Walters, Stockport; Charles John Gibb, Newcastle-on-Tyne; Charles William Izod, Fladbury; Thomas Simpson, Lincoln; Henry John Waterland, Thealby; John Lloyd, Cerrigydwdion; John Jones Parrish, Dudley; Samuel Osborne Habershon, Rotherham; Howard Fred. Johnson, Birmingham; John Packer, London; Richard Branwell, Penzance; John Willan, Kirby Lonsdale; Joseph Marshall, Upwell; Simon Caldcleugh, Durham; Samuel Clewin Griffith, London.

Admitted Thursday, March 25th:—Richard Swan

Finch, Salisbury; William Lascelles Norris, Stourbridge; James White, Chester; Henry Nicholson Settle, Leeds; Thomas Armstrong Cammack, Spalding.

Admitted Thursday, April 1st:—George Burton Payne, Birmingham; Henry Vevers; Thomas Balle Forster, Plymouth; John Lane Cutcliffe, South Molton; George Augustus Hartelbury Hepworth, Tewkesbury; James Tarzewell, Dorchester, Dorset; George Herring, Yarmouth; John Ingman, Trenddyn, Flintshire; William Nowell, Dewsbury; John Jessup Sewell, Fendrayton, Cambridge.

OBITUARY.

Died, March 30th, at St. Albans, aged 53, John Coales, Esq., Surgeon, one of the Magistrates of that borough.

April 11th, at Bishop's Stortford, J. J. Cribb, Esq., Surgeon, late of Cambridge.

BOOKS RECEIVED.

A Treatise on the Human Ear, with New Views on the Physiology of the Tympanum. By J. W. Moses, M.D., M.R.C.S., &c. St. Asaph. 1847. 8vo., pp. 18.

An Essay, Literary and Practical, on Inversio Uteri. By John Green Crosse, M.D., FR.S.. F.R.C.S., Senior Surgeon to the Norfolk and Norwich Hospital, &c. &c. Part II. London: Churchill. 1847. 8vo., plates.

Practical Remarks on the Inhalation of the Vapour of Sulphuric Æther, &c. By W. Philpot Brookes, M.D. London: Churchill. 1847. 8vo., pp. 68.

Our present Gaol System deeply depraving to the Prisoner, and a Positive Evil to the Community. Some Remedies proposed. By Joseph Adshead, Author of "Prisons and Prisoners," &c. 1847. 8vo., pp. 107.

TO CORRESPONDENTS.

Communications have been received from Dr. Cullen; a Member of the Association; the Sheffield Medical Society; Mr. C. Hawkins; Mr. J. F. Clark; Dr. Radford; Dr. Holbrook; Dr. Chambers; Mr. G. King; Mr. H. Sharp; Dr. J. Campbell; Mr. Worthington; Mr. Storrs; Mr. H. Stead.

Vaccine Matter.—Mr. P. Fernie, of Kimbolton, Hunts, will feel greatly obliged by any of the readers of the *Provincial Medical and Surgical Journal* supplying him with a small quantity of active vaccine virus.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

A SKETCH OF THE HISTORY AND TREATMENT OF INSANITY.

By H. S. Belcombe, M.D., Senior Physician to the County Hospital, and Physician to the Retreat, York.

Valeat quantum!

I commence this paper by acknowledging my obligations to M. José, Membre de l'Institut Historique de Paris, for his able memoir on the "History of Insanity," and for the opportunity thus given me of freely translating a great part of it for the benefit of the English reader. I have, in addition, endeavoured to carry out some views upon the nature and treatment of this singular disease, which, though they may advance no novelty, may merit some attention, as being the result of much experience,—may conduce to calm observation and calmer conclusions,—and may divest the subject of much metaphysical subtlety, in which it has pleased many writers to involve it.

History is an inexhaustible mine, from which science, art, literature, language, politics, can be enriched; and at no period has it been more searched into than at present. The old historians are examined, translated, commented upon in various ways, and perhaps no science has drawn more from this source than that of medicine. Be that as it may, there seems in this wide field a place not equally cultivated; or, to drop all metaphor, it appears to me, that from tracing the periodic history of insanity, some more complete intelligence as to its forms, its mode of treatment, and its cure, is yet to be obtained.

The following paper is merely an attempt at an object which is surely desirable, though I must readily grant that much more time, and much more information, than my leisure or my abilities can supply, are requisite for its fulfilment:—

If insanity is more prevalent now than at any former time, (a position which may be doubted,) it is not so with its causes, which, with the exception of a few, always arising from some dominant action of the period, and connected with the events proceeding from it, are the same to day as formerly. In all times, and under all climates, hereditary constitution, habitual drunkenness, disappointed ambition, wounded feelings, unbridled passions, political even moral antagonism, have been the most ordinary causes of mental diseases.

History affords us, from the Pythoness of Delphi, down to the hallucinated of the Thebaid, and the possessed of the middle ages, the means of classing those cases which have been the subject of many a drama, many an episode, many a romantic tale;* and philosophy can now teach us, that in contemplating such pictures, at once so sad yet so animated, that we there find a perfect reflexion of human nature. It is the picture of humanity, with its passions, its revolutions, its errors, its prejudices, its systems, crimes, and virtues,—a picture so exact, that it is shewn to us without disguise; in it are seen emperors and kings, ministers and courtiers, poets, painters, warriors, legislators, martyrs to chastity, and the victims of incontinence. From Nebuchadnezzar to Saul, from the Greek dramatists, through the history of many of the Roman emperors, let alone that of the early period and of the commonwealth of Rome, down to the times of Rousseau and our own incendiary, Martin, there are not wanting opportunities of writing it fully and entirely.

MENTAL ALIENATION.

It can be established, that the therapeutics of mental disease have been in all times conformable to its etiology, or in other words, that the treatment has always been in relation to the assigned cause of the malady. Thus history shews us mental alienation considered as a disease, *sacred*—sent especially by the Almighty, and so more particularly held in superstitious favour, as among the Pythonesses; or otherwise, as a chastisement from the Divinity, and then its treatment submitted entirely to religious ordinances. The alienated, considered as victims of the anger of the Gods, would necessarily be delivered over to the ministers of their altars, to obtain any relief from their misery. This relief was rarely implored in vain, and not unfrequently the cure was the reward of the ardent faith of the sufferer, let alone the pomp with which the preparatory ceremonies were performed, and the numberless forms to which the patients were subjected before their admission into the sanctuary. If to these be added the rigorous fast during many

* Particularly the madness of Ajax, who, among other vagaries, flogged unmercifully a great ram, whom he took for his rival Ulysses. *Vide* also the madness of Orestes.

days,—the saner faculties worked upon by all the modes that superstition knows how to employ,—the imagination excited by miraculous details,—by the distractions of the voyage,—by the hope of relief from the unknown agent, can it be doubted or wondered at, that frequently some great cure or sensible re-action would take place?

Nevertheless, mental alienation, better studied in its symptoms, in its causes, and in its effects, was deprived by the Pythogoreans of its divine prestige, and reduced to a simple cause, depending upon some affections of the liver—of the spleen—of the stomach—of the brain; then emetics and purgatives became the most usual therapeutical agents, perhaps entirely the whole means. Hellebore, with its mythological reputation, derived from those ages, has descended even into our own; but alas! in our hands it has not produced the miraculous effects that it performed under the administration of Melampus. This physician was an inhabitant of Argos, and in his time did many remarkable things, also performing wonderful cures. Herodotus relates his history; he is also mentioned by Homer, in his "Odyssey."

Hippocrates gave the last blow to this *divine therapeutic*, which the blind zeal of paganism had received; while adopting the ideas of Anaxagoras and Clayomenus, he extended the means of treating insanity according to the etiology he had established. He asserted and proved the beneficial influence upon this disease of other derivatives; also how effectual in the cure were gymnastics, variety of occupation, change of climate, &c.; and hellebore, long considered as a miraculous remedy, was now only proposed to be administered as the most efficient purgative. The impulse being thus given, other observations were presently obtained. Erasistratus was the first to refer maniacal affections to lesions of the nervous centre, and from thence deduced his celebrated cure of Antiochus Soter, who was maddened by his love for his mother-in-law, Phila.

Celsus, who flourished under Tiberius, excelled in his moral treatment (as it is generally called,) of insanity, and has left rules admirably adapted, even for the present time. It is curious, however, that he strongly recommended the modes of severity which for so long a period have cast such a blot upon humanity in the treatment of this affliction.

Aretæus,* after him, occupied himself less with the treatment than the causes of insanity, preparing the way for Cælius Aurelianus,† whose superiority of knowledge can only be appreciated by presenting a rapid exposition of the precepts he has left. Thus:—"The apartment of the patient should be of moderate temperature, lighted by a window from the upper part, on the ground floor, and away from noise, furnished with a bed firmly fixed, and so placed that the patient cannot perceive who enters or goes out. If the excitement prevents the use of the bed, the straw, which must be the next resource, should be well chosen, and conveniently arranged. All wounds and contusions should be carefully washed and dressed. The attendants should be enjoined not to permit visitors, not to exasperate by rudeness or blows, at the same time not using too much condescendence, but letting the maniac see that his faults are known, and that it will be to his advantage to amend them. If an ascendancy be obtained, care should be taken not to compromise it by too frequent visits; the state of the pulse will indicate if bleeding be useful; occasionally it may be necessary to employ restraint, and this should be done with great caution, with as little force as possible; the ligatures should also be made of some soft and pliable substance, otherwise the paroxysm of fury is increased instead of being abated."

Then follows the advice concerning aliment, the evacuations, the indications, where it may be considered necessary to shave the head, to apply cupping glasses, leeches, and revulsives of various kinds. Cælius being much averse to the use of opium, yet anxious to relieve the "insomnium," which he considers of high importance in the case, recommends a hammock, the monotonous and gentle noise of water falling from a height, the application of warm sponges to the eylids.

As occasion serves, recourse should be had to walking, singing, reading, conversation, even the theatre; each patient should be treated in this way according to his accustomed condition of life, and should be induced to feel an interest in his former employments and occupations; every opportunity should be seized of preventing weariness, or the patient relapsing into the thoughts and modes of feeling which may well be called the atmosphere of his malady. In conclusion, Cælius animadverts strongly upon those theoretical practitioners, some who prescribe a complete imprisonment, others total abstinence, others bodily inflictions of punishments, others active refrigerants, others even drunkenness, others music, without discriminating the cases they had to deal with. He was well aware that madness is often the consequence of the abuse of fermented liquors; that music, where it might calm one in ten, would excite the others. So also he attacked those practitioners who recommended love as a means of cure. Is it not absurd to suppose, he says, that love, itself a passion, can ever be the means for promoting a cure of an excitment still more violent. In truth we are obliged to confess, what all well-instructed men must feel, that the ancients have stated what we repeat as new, and that very frequently, we are only very poor plagiarists.

Be this as it may, this doctrine of Cælius Aurelianus,

* Aretæus, the Cappadocian, supposed to have flourished in the time of Vespasian.

† Supposed to have flourished in the second century, and said to be a Numidian.

stamped as it is with the marks that distinguish the true observer, concludes all that we possess from ancient history, on the treatment of mental alienation. The way opened by the genius of the physician of Sicca was never followed by his successors, and for fourteen centuries, the therapeutics of insanity retrograded, so as to equal, if not to surpass, in absurd and barbarous practices, in superstitious prejudices, those of the earliest days of ignorance. Human reason then appeared to soar, only to fall with more violence, like Montaigne's drunken man, who, being set straight on one side, tumbled down on the other.

In the mean while Christianity, in working an entire change in religious belief, altered also very much the frame of human opinions. Eastern imagination vehemently exaggerated the severity of the Christian doctrines. It was soon assumed that man was in a constant strife with the genius of evil, personified in the devil, who from that moment was considered the cause of all the evil both of the intellectual and the moral world;—to him alone was attributed all the different forms of insanity, except those of imbecility and idiotcy, which by a strange confusion of ideas were considered a sort of angelic state and an object of worship. The cause of the disease being thus simplified, the treatment became equally so;—the madman was possessed, and it became necessary to deliver him from the demon. The physician here had nothing to do, the patient entered a religious house, and exorcisms became the only means employed. The Jews seem to have received some additional notions concerning evil spirits and their operations from the Chaldeans, and after their return from the captivity, to have ascribed many diseases and disorders to these invisible agents, besides those which were to be accounted for by natural causes. In this the early Christians followed them, and it is probable that mad, melancholy, and epileptic people were accounted to be possessed, at least for the most part, in the early centuries.

Every form of alienation was considered as so many methods adopted by the demon to manifest his presence in the body of the patient; hence, also, were multiplied all the evils of a disturbed imagination. Compacts were made with the devil,—sorcery—charms—amulets—wolfmen,—all gave a variety to the forms of insanity. All persons labouring under hallucinations were burnt, hung, or suffocated, without pity. All those thought possessed were exorcised. Various places were celebrated for the cure of insanity through the relics of Saints. The pilgrimage to St. Maur, near Paris, was the most celebrated, and continued so, down to 1735. The Abbe Lebœuf tells us that during the four hours which the matins occupied, the patients crowded in the church, cried out with all their might, "St. Maur send me cure and health," and when any one had repeated three times following this prayer, he was judged to be cured; and then, a miracle! a miracle! was shouted out; so great indeed was the uproar, that it was impossible to hear the voice of the preacher. As for those whose violent paroxysms rendered them dangerous, they were placed in the public establishments, and Reil thus draws a picture of their mode of treatment:—"These miserable beings, as if they were prisoners of state, are thrown into the lowest dungeons, where the eye of humanity never penetrates; they are left there under the weight of chains which injure their limbs, and amid the stench of their own ordure. Their appearance is pale and fleshless. They are shown as a sight for public curiosity, and greedy attendants expose them as they would wild beasts. They are crowded together pell mell; fear is the only discipline employed,—whips, chains, the only means of persuasion, until the time comes when nature ends their miseries."

This picture of the treatment of the insane in Germany, applies with a fearful reality to that pursued at the same period in Great Britain, France, Italy, and indeed the whole of Europe. As to the physicians, we find them during this long period of many ages, forgetful of the admirable lessons of Celsus, Aretæus, and Cælius Aurelianus, involving themselves in the ridiculous doctrines of the humoral pathology, concerning black bile and phlegm. Some, however, less the slaves of received prejudices, employed a treatment based upon observation and experience. Alexander of Tralles, Marcellus of Sida, Forestus, Sylvaticus, Sylvius, Professor of Medicine at Leyden, Plater, Sydenham, Sennert, Highmore, Willis, Baglivi, Valsalva, and his disciple Morgagni, have left some useful precepts, but which have had no particular influence upon the progress of the curative treatment of insanity.

At length, in 1792, Pinel appeared. By his persuasion, eighty violent madmen, the terror of their keepers, and reported incurable and dangerous, were freed from their chains, and placed under a mode of treatment, which produced a cure in several of them. Thus was the first blow struck; the mental therapeutics established 1500 years ago by Cælius Aurelianus once more triumphed; bad treatment, corporal violence, was for ever laid aside. From that period psychological medicine, varying its resources according to the forms of the disease, restores to themselves, to their families, and their country, one half of those placed under care. These suggestions were soon listened to in this country, and great effects were made to modify the abuses then so called, and to improve the condition of patients, as well as to establish better principles of treatment. We all know how the Society of Friends came forward for such purposes, but the only remark I will make here is that it was not a love of cruelty that instigated the mal-practices, but erroneous and ignorant impressions.

I think an historical sketch of the almost infinite

varieties of mental alienation is thus worked out, which not only proves its connection with the events of history, but also the impossibility of establishing one particular mode of treatment for all cases; it seems as if four periods could be distinctly marked,—the first, where the disease was presumed to be sent from Heaven, either as a *gift* or a *punishment*, in the latter case alone a cure was solicited by the ministers of the religion; the second, where the malady is referred to a morbid state of some one organ, or of several organs, and then treated by evacuants; the third, where it is attributed to some malevolent being, and then to be subdued by exorcisms or corporal violence; finally, the fourth, in which the etiology of the disorder, better established, perceives the more sensible opinion of the second period, frees itself from the folly and nonsense of the first and third, and so multiplies its curative resources that the general fact is now established, that at least one half of the cases of insanity admitted into public or private institutions are capable of cure.

This is surely a valuable result, but there is a summation to be made. Is there any hope of perfect cure to be obtained? Is there any probability of so grievous, so afflicting a malady being extirpated? I fear not; it is a disorder which spares neither age, nor rank, nor condition, nor fortune; it seems interwoven with the institutions and affections of civilized society; those who are the sufferers are often the victims of the ingratitude, of the perfidy, of the injustice of their social relations and business in the present active community of the world. Neither must we be permitted to forget its hereditary influence, nor the immediate influence of our own passions, desires, and feelings, erroneous education, ambitious projects, mortifying results, and on the other side joyous and successful consequences. All these act with energy upon the human mind, and however mysterious the union of corporate and mental capacity may be, my long experience produces to my mind this deduction,—that there is not a faculty or propensity given for man's condition in this world that may not become deranged, or in other words diseased, like any other function.

One reason of the especial horror with which mental alienation has been heretofore contemplated, may be the want of knowledge of its obvious source in the physical organization. Delirium, as a consequence of fever, is a temporary mania, and however painful its manifestations may be, there seems a cause to which the hallucination may be referred, and its departure expected with the cessation of the exciting cause; but hitherto, in mania, properly so called, there has been a readiness to put a kind of metaphysical or moral construction upon the whole series of distressing symptoms by which it is characterized.

Now, however, a brighter era appears, the morbid manifestations are better understood, the nosology is reconstructed, it is observed to obey certain laws, and experience teaches the practitioner in many instances to be aware of, even to predict, the form of disease that will occur, and in a large proportion of recent cases, a cure is not only expected, but generally performed. Much improvement in the department of the medical treatment has taken place, the routine system of bleeding and purging, which descended from father to son, as stated in a committee of the House of Commons, has been utterly condemned; the secret remedies, the green and white powders, so long the resource of impudent empiricism, have been consigned to oblivion, and a rational practice, founded on rational views, of symptoms as they present themselves, established.

If it be asked what there is that we have to treat in insanity, I grant the question is a difficult one, yet something like an answer may be attempted. Language is not always equal fully to elucidate our ideas, or in other words, our knowledge may not be so exact as to clothe them in appropriate terms. I think this is our great difficulty here, yet I apprehend, that in the various forms of insanity, the cerebral centre is in a state of irritation. We all know how hysteria can simulate every disorder in our nosology, and how long organs may continue to be affected, even to a most suspicious degree of disorganization, yet the part be left intact, untainted, perfect in its work, when the disease has left it; and in this way I think much of the history of insanity may be written, for irritation admits of various actions being conjoined with it. There may be inflammatory action to a certain degree, congestion, local disorder of nerves, yet the irritative form of the disease may be the *most important, progress, decline*, call various sympathies into action, and finally, leave the patient to a happy recovery.

I grant also entirely with Dr. Good, that this diseased state may be a secondary affection, dependent upon a morbid condition of the epigastric or some other abdominal organ,—for in whatever it may consist, and whatever symptoms may arise, it is not till the sensorium is by degrees associated in the chain of unhealthy action that the signs of insanity are unequivocal; also dyspeptic and other abdominal symptoms are not unfrequeutly brought on by a previously diseased state of the mind, and it is hence peculiarly difficult, and perhaps, in some cases, altogether impossible, to determine, where we are not acquainted with the incipient symptoms, whether melancholy or hypochondriasis, has originated in the state of the abdominal viscera, or of the cranium. Where, however, we are made acquainted with the history of the incipient symptoms, we have a tolerable clue to guide us, and the experienced practitioner may for the most part safely decide, that the region primarily affected is that which first evinces morbid symptoms, and hence there will be as little difficulty in assigning the origin of hypochondrism to a morbid

condition of one or more of the digestive organs, as in referring the greater number of cases of mania to a primary misaffection of the brain or the nerves. But in what that misaffection consists, is a question that has never been settled to the present hour, and from our total unacquaintance with the nature of the connection between the brain and the mind, never will be in any very satisfactory manner; "indeed, it seems only by the curtailment or suspension of certain functions, by the excess of others, and by the altered balance and connection of all, that a sort of analysis can be obtained of the nature of mind, which its waking and healthy acts cannot equally afford either to individual consciousness, or the observations of others."—*Dr. Holland.*

I therefore must conceive that he is the most competent to appreciate the nature and peculiarities of insanity, and the best qualified to attempt its dislodgment from the bodily organization, who, fully assured that more or less of physical disorder must necessarily have place in mental hallucination, is at the same time aware of the great difference between mere bodily disease, and the attack upon the nervous centre producing disease of the understanding,—that the distinction of the different kinds of insanity is a matter of much delicacy, for these varieties pass into each other frequently and imperceptibly—that there are grounds for supposing no sensations wholly new are introduced into the mind of a patient by the disease, or that the immediate operation of the senses are perverted, the illusions being principally false combinations of former ideas, with the additional persuasion of their actual existence,—and who has candour and intelligence enough not to form one particular or one exclusive treatment in his system of management.

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(*Fourth Series of Experimental Researches.*)

By William Addison, M.D., F.R.S., Malvern.

(*Continued from page* 203.)

XII. Regular, Irregular, Retrograde, and Ascending Metamorphoses in the Textures of Plants.

That part of botany which treats of the gradual transmutation of leaves into the various organs of a plant, which shews that bracteæ are leaves affected by the vicinity of the fructification,—that the calyx and corolla are formed by the adhesion and verticillation of leaves,—that the filament is a form of the petiole, and the anther of the lamina,—and, finally, that the ovarium itself is a convolute leaf, is called morphology.

This doctrine seems to have originated with Linnæus, was deeply entered upon by the celebrated Goethe, has been universally adopted in Germany, and been since received in France and England by most of the botanists of the present day.

The first idea of the subject appeared in the second volume of the tenth edition of the *Systema Naturæ* in 1759, and in 1760 the propositions were sustained by Linnæus, in a thesis prepared in the name of his pupil Ullmark, and called the *Prolepsis Plantarum.*

It would be out of place here to enlarge upon botanical facts, about which there is no question, or upon principles regarding the *regular metamorphosis* of plants, which have been firmly established.

"There is not only," says Dr. Lindley, "a continuous uninterrupted passage from leaves to the bracteæ, from bracteæ to calyx, from calyx to corolla, from corolla to stamens, and from stamens to pistillum, from which circumstance alone the origin of all these organs might have been referred to the leaves; but there is also a continued tendency on the part of every one of them to revert to the green parenchymatous texture, and even to the form of the leaf." Examples of *irregular metamorphosis* of some part or other of vegetable structures, are innumerable. Roots and tubers undergo a vast variety of changes, chiefly the effects of domestication. The celery, the root of which is fibrous when wild, produces under domestication a fleshy round root like that of a turnip, known in gardens by the name of celeriac. In short, stem, leaves, flowers, and fruit, exhibit a thousand irregular metamorphoses, for interesting examples of which, the reader is referred to Professor Lindley's "Introduction to Botany."

Examples of a *retrograde metamorphosis* are almost equally numerous. "In the monster *Muscari monstrosum*, a small cluster of branches, covered with minute imbricated coloured bracteæ, is produced in lieu of each flower. Here all parts of the fructification, instead of remaining at rest to perform their functions, are attempting, but in vain, to become organs of vegetation; or in other words, to assume that state from which, for the purposes of perpetuating the species, they had been metamorphosed by nature." The general resemblance of the calyx to the ordinary leaves of vegetation is well-known; its green colour and tendency to revert into as many leaves as it consists of divisions, especially in double roses, is so notorious, that it need not be insisted on. In the cowslip and polyanthus, the calyx is frequently formed of five perfect leaves, in no respect different from the others, except in being a little smaller. Several instances have been observed in which petals have reverted to the state of leaves. In a *Campanula Rapunculus*, seen by Röper, the corolla had become fine green leaves like those of the calyx; the same was found in an individual, of *Verbascum pyramidatum*, described by Du Petit Thouars. Proliferous flowers of Geum and Rosa, in which the petals were converted into leaves, are adduced by Linnæus.

That the anthers are alterations of the margins of petals there is no difficulty in demonstrating. In *Nymphæa* the passage from the one to the other may be distinctly traced. In double roses and camellia's the precise nature of a retrograde metamorphosis is shown in a very instructive way. If any double rose be examined, it will be seen that the filaments of those stamens which are next the petals are expanded and coloured like the petals; and sometimes the perfect lobe of an anther will be found on one side of an abnormal petal, and the imperfect remains of another on the opposite side, proving that the unnatural excess of petals has, in these cases, been produced by a retrograde morphology of the stamens. The conversion or retrogradation of stamens into green leaves is more uncommon, it was seen by Röper in the *Campanula Rapunculus* already referred to, and Du Petit Thouars found the stamens of *Brassica Napus* converted into branches, bearing leaves.

Nothing is more common than to find the pistil converted either into petals or into green leaves. Its change into petals is to be found in numerous double flowers, as for example,—double *Narcissi*, *Hibiscus Rosa-sinensis*, wall-flowers, ranunculuses, saxifrages, and others. Nothing again is more common among roses than to find the ovaria converted into perfect leaves, and the same fact is often met with in the double cherry.*

There are also many instances among plants in which organs advance beyond their natural stage of metamorphosis, attaining a higher, as well as falling back into a lower, type.

In the tulip a bractea is occasionally present upon the scape, a little below the flower, partaking of the nature both of the leaf and the petal. In *Aquilegia vulgaris* the petals consist of a long sessile purple horn, with spreading margin, while the stamens consist of a slender filament, bearing a small oblong yellow anther; in regularly formed flowers, nothing can be more unlike than the petals and stamens, but in some of the double flowers the horned petals are changed into stamens. Several instances are known of ovula being borne by the stamens; it occurs continually in *Sempervivum tectorum*, and Dr. Lindley has seen it in the double Barbadoes lily, and the wall-flower. There is, therefore, as he observes, "no doubt of the truth of the theory of morphology which is now universally adopted by all philosophical botanists."†

It is well known that gardeners, if they wish to have double flowers,—flowers whose pistils have changed to petals, or whose stamens have undergone the same retrograde change, save the seed, (the few at least that may chance be formed in the ovaria of the double flower,) or they select the seed of a more perfect individual, growing nearest to the one whose retrograde changes they wish to perpetuate. Experience tells them in the latter case, that they will be more likely to succeed in their wish to obtain a double flower, than if they chose another plant, growing under the same external conditions of soil, light, heat, and moisture, a few yards off. Hence from this and many other similar facts, it appears that there is an *original inherent disposition* imparted from the parent plant to the seed, in virtue of which alone, independently of external conditions, the young structure will exhibit the same morphological aberrations as those which existed in the stock from which the embryo sprang.

"It is probable," says Dr. Lindley, "that all plants have a particular range, (in some cases more extended than in others,) to which they are best suited, in consequence of their constitutional peculiarities,‡ which become visible by the effect produced from a change of situation, although not otherwise appreciable. The two great external agents by which they are affected, that is to say, soil and atmosphere, will, in their natural situations, be nearly uniform; and so long as this uniformity of the conditions under which they exist continues, their structure will remain unchanged; but let an alteration take place,—their atmosphere, for instance, change from that of the valley to that of the mountain,—the soil from alluvial deposit to chalk or slate, and the mean temperature under which they are found fall several degrees; or remove a plant from its native spot, and cultivate it in the rich soil of a garden, thus submitting it to what may be called domestication. Under such circumstances, an alteration will be produced in the structure of the plant, which will become manifest by external characters. This is what is called irregular metamorphosis. We are ignorant of the specific causes by which the metamorphosis is effected, but we know that it is the leafy texture, and the secreted matter, or proper juices, of the plant, which chiefly manifest their sensibility of change."§

It is evident then, that there are two conditions operating in the irregular or retrograde metamorphoses of plants,—the one a constitutional peculiarity or inherent disposition, derived from parent to offspring; the other, unfavourable external conditions. The former or constitutional disposition may prevail over the most favourable external conditions, and the latter, the external conditions, may modify the morphology of the most perfect embryo, and cause a degradation of its textures. Either of these events would be productive of abnormal form and qualities—that is, of diseased structure.

Before proceeding to the farther consideration of

* The year 1845 was remarkable for a total absence of blackberries, there was hardly a fruited bush to be seen, and on examining the reason it was found that all the pistils were metamorphosed into *bracteæ*.

† See Lindley's "Introduction to Botany," Book vii. Ed. 1832.

‡ Inherent disposition.

§ See "Introduction to Botany," &c.

the phenomena which exemplify, and appear to me satisfactorily to prove, the existence and operation of a morphological law in animal textures, let me recapitulate the points which are settled and established with regard to plants:—

1. *Regular metamorphosis* is the process by which the type, texture, and form, established by Nature for the species, are perfected, and handed down from parent to offspring without fault, deviation, or change. It is the ultimate fact of living structure. Why is it that there is one form, one colour, and one property in one part of a plant, and others in another, &c.? We do not know, all we have to do is to study the normal form and quality of every portion of the structure of the individual during the morphology, so that we may learn the order of Nature, and thereby estimate the kind and nature of observed changes.

2. *Irregular metamorphosis* occurs when parts are checked or stunted in their growth, or when they become unusually exuberant. The structural elements are unchanged, but there is some deficiency or excess. Leaves and fruit undergo manifold changes of this kind, the more observed because the gardener promotes and fosters the irregularity. By an irregular metamorphosis leaves become more succulent and roll inwards, forming what is called a heart, as in the cabbage and the lettuce. If the green parenchymatous texture be exuberant, and extend more rapidly than the veins and margins, they pucker; and if the parenchyma and margin are together in excess, then the leaf is copiously and curiously curled, as in cress, savory, endive, &c., &c.

3. *Retrograde metamorphosis* occurs when the texture and form of a part are completely changed, when later-formed organs assume the structural elements of lower or preceding ones, beyond which, in the natural course of things, they ought to go.

4. *Ascending metamorphosis* is the term applied to parts that do not observe the limits of, but pass above or beyond, the natural type,—as when the sepals of the calyx assume the colour and textures of a petal,—when petals assume the form and function of stamens,—or when stamens bear ovaries.

5. That the causes or conditions operating in these morphological phenomena are two-fold,—external conditions, and the inherent disposition.

(To be continued.)

EXTRACTS FROM AN ESSAY ON PERICARDITIS.

By M. M. de Bartolome, M.D.

(Read before the Sheffield Medical Society, February 18th, 1847.)

Pericarditis is generally defined by authors "An inflammation of the serous membrane lining the pericardium, and covering the external surface of the heart." This definition is, I think, insufficient; for the frequency of this affection consequent upon, or concomitant with, rheumatism, sufficiently shows these diseases to be somewhat analogous, and that, very probably, pericarditis generally, if not always, first attacks the fibrous pericardium, although from the intimate connection existing between the two layers of which the pericardium is composed, the inflammation quickly extends to the serous membrane. Corvisart, whose description of the disease almost all succeeding authors seem to have followed, pertinently enough enquires, "Why the fibrous pericardium should not, like all other solids of a similar structure in the body, be the seat of inflammation?" Analogy, and I may venture to add, facts also, lead to the conclusion, that in very many instances, the inflammation does begin in the fibrous pericardium. Many of the causes of pericarditis are such as produce rheumatism, and still more frequently rheumatism itself is the only assignable cause. Pericarditis often occurs as a vicarious affection on the disappearance of rheumatism; at other times the two diseases co-exist.

As rheumatism undoubtedly is the most frequent source of pericarditis, as it is essentially a disease of the white fibrous tissue, and as the synovial membranes of the joints become affected by it secondarily only, it is very probable, I think, that the fibrous pericardium being a membrane of the white fibrous structure, is the primary seat of the inflammation, and that the serous pericardium becomes affected, in the majority of instances, secondarily only. Laennec relates an example, which I think incontestably proves this to be sometimes the case, in which he found the heart enclosed in a bony case, which sent processes into the substance of the heart, even to its very cavities; and he satisfied himself by dissection, that it was developed between the serous and the fibrous layers of the pericardium. Other strong proofs of the analogy of pericarditis and rheumatism may be found, in the pulse of incipient pericarditis being generally the loose throbbing pulse of acute rheumatism, rather than the hard and tense pulse of inflammation of the serous membranes; and in the two diseases requiring very nearly the same treatment.

In rheumatism, general blood-letting to any extent is deprecated by many authors, as tending to induce a chronic form of the disease, or even pericarditis itself, as is believed by Drs. Fordyce and Alison, whilst local abstraction of blood is freely used. The early symptoms of pericarditis must be promptly met by local bleeding and counter-irritation; but venesection, to any amount, is rarely admissible. Indeed, it was thought by Corvisart, that blood taken from the region of the heart was more efficacious than when drawn from the general system.

Acute rheumatism generally attacks the young and vigorous, so does pericarditis; though the latter disease sometimes attacks children under the age at which they would be liable to suffer from the former; and patients suffering from either, are liable to a recurrence of the disease, and are particularly exposed to suffer from pericarditis if previous attacks of rheumatism should have been treated by copious depletion.

The most common causes of pericarditis besides rheumatism, are blows or excessive pressure on the præcordial region, inflammation propagated along the lungs or pleura, checked perspiration, cold, the abuse of spirituous liquors, and the exanthemata.

Morbid Anatomy.—After the inflammation has attacked the serous pericardium, the morbid alterations it produces may be described according to the four following heads:—Redness and vascularity of the membrane; effusion; formation of false membranes; and their conversion into cellular tissue, fibro-cartilage, bone, &c. But I must confess that I am at a loss how to describe what I consider to be the first stage of the disease—namely, that in which the fibrous pericardium alone is affected; for, as the fibrous tissue in the neighbourhood of joints does not present after rheumatism any pathological appearances, except in a few protracted and very severe cases, we cannot expect to find any morbid alterations in the pericardium when the disease has existed in its fibrous layer only. Thus it happens, as Laennec assures us, that in many instances he could find no trace whatever of the disease, although from the symptoms which had characterized it, he was persuaded that it had been the only cause of the patient's dissolution. In all such cases, I am convinced that the inflammation had existed only in the fibrous pericardium, and had produced its fatal effects by the impediment which it must have offered to the free action of the heart. The case already alluded to as described by Laennec, seems clearly to have been one of this description.

The redness over the pericardium is seldom uniform; sometimes it assumes an arborescent appearance, but most commonly shows itself in small patches, or in dots, alternating with the natural colour of the membrane. This alteration of colour is not invariably present after pericarditis, for Laennec found in some cases, that although the symptoms during life, and the thickness of the false membranes, indicated the inflammation to have been very severe, yet on the most attentive examination, he could discover no redness whatever. Although some have asserted that the redness may have disappeared after death, as it does from the surface of persons who have died of erysipelas, yet I think that the experiments of M. Scoutteten* go far to prove that inflammation of a serous membrane will invariably exhibit increased redness after death.

The effect of inflammation in almost all textures of the body, is the effusion or exudation of a particular morbid secretion. In pericarditis it generally consists of coagulable lymph, accompanied by more or less serum. When only lymph and serum are effused, the latter sometimes exceeds the former in quantity. The effused lymph forms a membranous covering, more or less perfect, on the surface of the pericardium, and according to Laennec, rarely presents the equable surface peculiar to the membranes formed during pleurisy, but on the contrary, it is pitted, mammillated, and rough. The pericardium, whatever changes may be going on within it, is very rarely thickened, the false membranes having been sometimes, according to Dr. Hope and M. Bouillaud, confounded with thickening of the pericardium itself.

Diagnosis.—The diagnosis is not always easy. The disease has been mistaken by some of the best practitioners for affections of other organs, which, on dissection, have been found perfectly healthy. Laennec assures us that he often found on dissection all the evidences of the existence of pericarditis, when nothing had occurred during the life of the patient to excite the slightest suspicion that such a disease was present: and again, that frequently he could find no trace whatever of the disease, when he was sure that it had been the only cause of the patient's dissolution; and he observes that pericarditis is a disorder, the existence of which, during the life of the patient, the most able physicians rather guess at than recognize. Dr. Latham mentions two cases in which the disease was mistaken for disease of the brain, and treated accordingly, but dissection proved them to have been cases of pericarditis. Andral and Corvisart mention two similar cases; the latter was of opinion that the cases where diagnosis was most obscure, were always complicated with pleurisy, pneumonia, or some other disease of the thoracic viscera.

In opposition to this statement may be quoted Laennec, who says that the most complete latent affections he has met with, were in patients whose thoracic viscera were in other respects quite sound, and who had died of disease of the abdomen.

The pulse at the commencement, that is, when the fibrous membrane alone is affected, will generally be found to be that of acute rheumatism, but will vary in proportion as the serous membrane becomes affected; and it is owing to this that the pulse of pericarditis is so different in different subjects, and so variable throughout the course of any particular case. We cannot therefore form our diagnosis by the pulse alone, as it may derive its particular character in some cases not so much from the affection of the pericardium, as from rheumatism in other parts of the body on the one hand, or from inflammation of some other serous membrane on the other.

All authors seem to agree that the most unequivocal sign is the presence of pain over the region of the heart, particularly if aggravated by pressure, in whatever way excited,—whether by full inspirations, change of position, or artificially. This latter circumstance has been known to aggravate it so intensely as to have caused a fit of syncope. "The pain," says Dr. Hughes, "which, according to my experience, is a constant attendant upon rheumatic inflammation of the pericardium, is fairly explicable by the inflammatory rheumatic affection of the fibrous external covering to the serous membrane, the fibrous tissue being the natural seat of rheumatism, of which pain is the most common, if not the universal, symptom."

It is frequently difficult to form a correct diagnosis of this disease. Inflammation of some other thoracic viscus may be readily mistaken for it; and by pressure, should it be applied, we shall excite pain, whether the heart or some other organ within the cavity of

* "Arch. Gen. de Médecine."

the chest be affected. Should this be the case we must mainly trust to the symptoms elicited by auscultation and percussion, which in the generality of cases will be sufficient to guide us; but in some obscure cases of pericarditis, we have only negative symptoms to judge by, and then we must decide of the nature of the case by the absence of such symptoms as characterize disease of other thoracic viscera, as for example, pneumonia, pleurisy, &c.

The inflammation may be said to be on the decline when the fixed pain, if there should have been any, degenerates into diffused uneasiness, and the peculiar vehemence of the heart's action gradually becomes the beat of merely accelerated circulation; but not until all the symptoms have altogether disappeared can we say that the inflammation has terminated. Even when they have entirely ceased, the patient is not for a long time safe against their recurrence, as they very often return when the patient resumes his original avocations. When the motions and sounds of the heart do not entirely regain their healthy standard, we may reasonably suspect that adhesions and lymph still remain.

Physical Signs.—The impulse of the heart is greatly increased, sometimes to such a degree as to be perceptible to the bystanders; it is generally abrupt and irregular. Whenever there is a contraction of the heart stronger than common, the jerking is immediately felt along the arteries. It is this that distinguishes the pericarditic pulse from that produced by merely accelerated circulation. This jerking sometimes remains for months after the inflammation has ceased. Dr. Latham limits the existence of the *bruit de cuir* to rheumatic pericarditis, but I think with Dr. Hope, that it is present in every form of the disease, except when the action of the heart is feeble. The condition which I think necessary for the production of the *bruit de soufflet*, whether in the healthy or diseased heart, is that the valves shall bear a larger proportion than natural, to the orifices which they close; or, in other words, to some impediment to the flowing current of blood. Thus in endocarditis, affecting the valves ever so slightly, the bruit is produced, whether the valves be simply infiltrated or studded with vegetations.

The same explanation may be offered to account for the production of the *bruit de soufflet* after the loss of a large quantity of blood—viz., that the force of the circulation and the quantity of circulating fluid being diminished, the capacity of the arterial tube, and indeed of the circulating system at large, becomes diminished, to adopt itself to the distending force, and the orifices contracting also, cause the substance of the valves to fill up a larger proportion of the area than natural, and to produce the bruit, just in the same way as if they were diseased.

We can easily satisfy ourselves of the truth of this assertion, by projecting a column of fluid through a piece of intestine or a dead artery, and applying the stethoscope over any point of it. When we hold the instrument lightly no bruit is heard, but the moment that we indent the vessel it is produced, distinct in proportion to the pressure employed.

Dr. Alison* does not attach much importance to the *craquement de cuir*, for he says that in many instances the disease runs its whole course without this sign being present, and in a few cases, some of them well marked in every other respect, which have come under my notice, I have not been able to detect it, though I have attentively watched for it.

Treatment.—The list of remedies which can be employed for the cure of pericarditis with decided advantage is rather limited. The abstraction of blood is generally ranked foremost by almost all authors, and of the different modes of accomplishing it venesection seems to be preferred; yet I think that this mode of abstracting blood is far from being absolutely necessary, and that in the majority of cases topical bleeding is preferable,—first, because it answers the same purpose as general blood-letting; and secondly, because it does not produce that distressing debility which seldom fails to follow venesection to any amount, and because it does not excite that reaction, so prejudicial when the lining membranes of the cavities of the heart, and particularly the valves, are affected. Our primary object must be to allay undue excitement of the heart; and general blood-letting has a greater tendency than topical bleeding to excite nervous irritability, which in itself is a cause of hypertrophy of that organ.

That general bleeding is not absolutely necessary, and that provided blood be abstracted the effects are the same in whatever way accomplished, is beautifully proved by a case related by Corvisart. The patient, a woman of middle age, was attacked by very severe symptoms of pericarditis, which were completely arrested on the third day, by the appearance of the menstrual discharge, and although it was unusually scanty and lasted only three days, (instead of nine, the usual period with this woman,) yet it was sufficient to stop the progress of the disease and to keep it stationary.

That topical bleeding by itself is often sufficient, is clearly shown by Dr. Hope, who assures us that he has seen a single, prompt, and abundant application of leeches, or a cupping, at once subdue every formidable symptom. Dr. Alison says, that in rheumatic pericarditis general blood-letting is not advisable, but that the repeated use of local blood-letting is most beneficial; "My results of this practice," he says, "have been much more successful than those of any other." I do not mean to say that I would in no case employ general blood-letting, but merely that I would not do so on every occasion; for, unless the symptoms are very urgent, I consider topical bleeding preferable. In cases where they are pressing I would bleed, though not to a large extent at first, and then trust entirely in patients of strong and plethoric temperament, to cupping, and in those of weak and debilitated constitutions, to leeches. Cupping, where practicable, I consider preferable to leeches, because we can abstract a greater quantity of blood in a less space of time. If the pain and the heart's immoderate action are not subdued by the first topical bleeding, it should be

* Clinical Lectures.

repeated; but sometimes, as already stated, such repetition is unnecessary. When there is pain at the epigastrium, and other signs of gastric irritation, I would recommend the application of leeches to the part, taking care to encourage the bleeding by warm fomentations and light poultices. Next to bleeding I would rank severe counter-irritation. Colchicum, digitalis, and antimonials, I have repeatedly employed with great advantage. The observation applies likewise to mercury.

When the disease recurs it generally has not the same intensity, and is, I think, more under the power of medicine; we should now abstain from employing the same active treatment as during the first attack, and should content ourselves with combating the inflammation by the moderate use of topical bleeding and counter-irritation.

ON SIMPLE ACUTE INFLAMMATION OF THE MEMBRANES OF THE BRAIN IN INFANTS.

By Dr. RILLIET, of Geneva.

(Translated for the Provincial Medical and Surgical Journal.)

(Continued from page 181.)

IV. General Description of the Disease.

Form, Duration, Termination.—Acute meningitis declares itself under two forms, to one of which we give the name of "convulsive," the other "phrenitic." We do not, however, wish it to be understood either that convulsions are never present excepting in the "convulsive" form, or that the "phrenitic" is the form exclusively characterized by perversions of the intelligence; we merely wish to notify by these terms the predominance of certain symptoms.

The convulsive form is most commonly seen in very young infants. It commences suddenly by an attack of convulsions, general or partial, with more or less febrile disturbance. There is neither vomiting nor constipation. When the convulsions, which are repeated at brief intervals, subside, the infant is left either in a state of agitation, or profoundly comatose, with squinting, and sometimes perfect hemiplegia. In certain cases there is an approach to sensibility between the fits, but the amendment is but momentary, and death rapidly approaches either by coma or during a subsequent paroxysm. The convulsive form of meningitis sometimes sets in more slowly, and the convulsions are not so closely approximated. The duration of this latter variety is longer, being from a week to a fortnight.

Phrenitic meningitis is commonly observed in early childhood, and in many respects resembles the acute meningitis of the adult. It commences with fever preceded by a rigor; violent headache ensues, with photophobia, vomiting, and sometimes constipation. The intellect suffers by the end of the first or second day, and the face assumes the peculiar wild look of the disease. Agitation and stupor alternate, and delirium is generally present. Subsequently there is grinding of the teeth, partial convulsions, rigidity of the limbs, a drawing of the head backwards, strabismus, and contraction followed by dilatation of the pupils. About the seventh or eighth day some of these symptoms subside; the vomiting ceases; but the fever still continues; the pulse and respiration are irregular; the belly is retracted, and finally partial convulsions ensue, followed by coma and death.

Diagnosis.—The diseases which are apt to be confounded with acute meningitis, are, as may be imagined, numerous. Before we mention these diseases, we shall enumerate those symptoms of the convulsive and phrenitic forms which are most worthy of confidence in a diagnostic point of view.

In the convulsive form, we should attach great importance:—1. To the constant repetition of convulsions at short intervals. 2. To the acceleration of the respiration, which cannot be accounted for by any pulmonary lesion. 3. To the absence of all visceral inflammation, and of any indication of an exanthematic eruption. In the phrenitic form, the cardinal symptoms are,—intense headache, accompanied by frequent bilious vomiting and constipation, followed by delirium and agitation, alternating with stupor.

Differential Diagnosis of the Convulsive form.—Convulsions in early infancy are very frequently symptomatic; but in this case they are seldom violent or so frequently repeated. Moreover, in the interval, the little patient recovers his sensibility, the respiration is not permanently accelerated, and the pulse quickly regains its normal standard. It must, however, be admitted that in many cases the diagnosis can only be established by the progress of the disease.

The distinction between convulsive meningitis, and other cerebral affections is still more obscure, and indeed it is often impossible. The error is not, however, one of importance, as the treatment, and too often the termination of all is the same.

The first disease which we shall endeavour to distinguish is *hydrocephalus, with infiltration of the pia mater*, the Wasserschlag of Gölis.

In certain cases this condition complicates inflammatory meningitis, and the main features of each are then undistinguishable. In other cases the "hydro-meningitis" is the principal lesion, and we find only slight traces of purulent effusion. This disease, like the one from which we wish to distinguish it, also attacks very young infants; it sets in with fever, and a violent attack of convulsions, or with agitation and stupor, with transient and fallacious signs of amelioration. The analogy between the disease and the convulsive form of meningitis is therefore perfect.

In *hæmorrhage into the arachnoid*, we observe repeated convulsions as the earliest symptoms, but they are in general less violent than in meningitis, and the coma does not ensue so rapidily. According to M. Legendre, children attacked with meningeal apoplexy, exhibit contraction of the fingers and toes,—a symptom which is not observed in meningitis; while, on the other hand, the excitement of the pulse and circulation which are witnessed in the latter disease, are not seen in meningeal apoplexy. *Hæmorrhage into the pia mater* also in some respects resembles convulsive meningitis, but it is a lesion of such rare occurrence that it need scarcely enter into our consideration.

These remarks conclude what we have to say respecting the diagnosis of convulsive meningitis from other organic lesions of the brain; but we must remember that the most important part of the diagnosis of the disease consists in its distinction from essential or symptomatic convulsions, since the treatment of the two forms of convulsion is obviously different.

What we have said in connection with "convulsive meningitis," applies equally to the phrenitic form. Cerebral hæmorrhage, encephalitis, &c., may be confounded with it without any great damage; but it is not so with regard to cerebral congestion, tubercular meningitis, and those sympathetic affections of the brain which arise during the course of the eruptive or typhoid fevers. The following paragraph deserves the earnest attention of our readers:—

Cerebral Congestion.—We have often propounded to ourselves the following question:—Ought we to consider those violent cerebral attacks, which either quickly prove fatal, or as rapidly subside, and the symptoms of which are precisely those which indicate the onset of acute meningitis, as real instances of that disease? *Post-mortem* examination in these cases discovers neither pus nor false membranes, but only simple congestion. Is this congestion to be regarded as the initiative stage of inflammation? The question is difficult of solution; but we nevertheless consider that it should be answered in the negative, and for these reasons:—Inflammatory products of the brain form with such rapidity, that its whole surface may be covered with false membranes in a few hours, consequently the cases we have just mentioned ought to be distinguished from meningitis, both anatomically and by their symptoms. The diagnosis may, however, be here plainly established by the following comparative table:—

Cerebral Congestion.	*Meningitis.*
Declares itself by sudden stupor or more complete insensibility, with dilatation of the pupils; or its first symptoms are acute delirium, with difficult respiration, quick small pulse, and slight convulsions. These symptoms appear almost instantaneously. Vomiting is for the most part absent.	In the phrenitic form, the first symptom is partial or general headache. Delirium does not appear in general until the lapse of twenty-four or thirty-six hours. Vomiting is generally present.

Cerebral Hæmorrhage.—In some cases cerebral hæmorrhage closely simulates acute meningitis. Headache, convulsions, delirium, vomiting, and constipation, mark the onset of both diseases, and it is, therefore, difficult to decide, with certainty, which disease is present. The best guide to a correct conclusion is the high febrile excitement which characterizes meningeal inflammation.

Tubercular Meningitis.—We now arrive at the most important portion of this essay, and shall endeavour to point out the main distinction between simple and tubercular meningitis. For clearness sake we would remind the reader of four circumstances:—1. That diagnosis is to be drawn from the ensemble of symptoms, and not from the individual characters of a disease. 2. The main element in forming our diagnosis is the consideration of the point of time at which the disturbances of the intellect and mobility originate. 3. That the invasion of tubercular meningitis may take place under three different states of the system—1st, after a longer or shorter duration of precursory symptoms; 2nd, during the progress of tubercular disease in other organs; 3rd, in perfect health. 4. That the first and third species are readily distinguished from acute simple meningitis; the error is more likely to be made between the latter and the second form. These preliminaries established, we shall proceed to lay down a brief summary of the differential symptoms as below:—

Simple Meningitis.	*Tubercular Meningitis.*
1. The children attacked are in general vigorous and well-developed, and do not exhibit any signs of tubercle. Their relations too, are healthy.	1. The subjects of tubercular meningitis are delicate, and often precocious children. They are subject to glandular enlargements, and chronic eruptions of the skin. Their blood-relatives generally bear the stamp of the strumous diathesis.
2. The disease may appear as an epidemic.	2. The disease is always sporadic.
3. *Prior condition.*—The attack takes place during robust health, or if it is secondary, it follows some palpable external cause, or arises in the course of a non-tubercular malady.	3. *Prior condition.*—The infant is observed to pine away and lose its flesh and strength. The disposition is altered, the appetite fails, and the *primæ viæ* become deranged.
4. *Mode of attack.*—Violent convulsions, intense fever, quick respiration if the infant is very young; or headache, fever, bilious vomiting. After a lapse of twenty-four hours, excessive agitation, delirium, and prostration.	4. *Mode of attack.*—Convulsions never the first symptoms; the transition from the first to the second period of the disease insensible; the coming on of the second stage marked by headache, vomiting, and constipation; the intelligence sometimes unaffected. When the precursory symptoms are absent, the disease is ushered in by vomiting, moderate headache, and fever.
5. *Symptoms.*—Headache *intense*, vomiting *incessant*, fever *high*, delirium *fierce*, constipation *moderate*.	5. *Symptoms.*—Headache *not intense*, vomiting *not so urgent*, constipation *obstinate*, fever *moderate*.
6. *Progress.*—Rapid; convulsions incessant.	6. *Progress.*—Slow.
7. *Duration.*—Death in 24 hours, in some cases; but generally at the end of the third day.	7. *Duration.*—More prolonged — a fortnight to three weeks.

We have thus gone through the list of the cerebral affections with which simple meningitis may be confounded, we shall now notice the distinction between it and certain formidable cerebral symptoms, which declare themselves without any appreciable lesion of the brain,—as for instance, during the progress of fevers. And first of—

Small-pox.—This disease is sometimes at the onset mistaken for meningitis.. The most important elements in the diagnosis, are the consideration of the reigning epidemic, the lumbar pains, and the time at which delirium appears, which in small pox, is seldom earlier than the third day.

Scarlatina.—In adynamic scarlatina, children frequently complain of headache, and are seized with vomiting. We must look for our guide to the state of the tongue and throat, and the great heat of the skin, taking likewise into consideration the fact of the prevalence of the disease at the time.

Typhoid Fever.—The same rules for forming a diagnosis are applicable in this disease as in small-pox, &c.; but in addition we are to remember, that in typhoid fever the headache is less intense than in meningitis, that the vomiting is less urgent. Some useful information may also be drived from the state of the lips and tongue, the pain in the body, the diarrhœa, and the state of the chest. Moreover, the symptoms which are analogous in the two diseases appear at different periods,—in meningitis at the commencement, in fever towards the termination.

(*To be continued.*)

CASE OF TRAUMATIC TETANUS: ADMINISTRATION OF ÆTHER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I beg to forward you the following brief report of a case of traumatic tetanus in which æther was most successful in arresting the spasm.

On Saturday, March 20th, I was called at 6 a.m., to Charles Prescott, a miner, residing two miles from this place. I found the left arm completely shattered by a large stone falling on it; he had not lost much blood, his comrade had tied a piece of cord tight round his arm, which completely checked the bleeding. He had walked home, a distance of a mile from the shaft where the accident occurred. I immediately amputated below the elbow-joint; three arteries required ligatures. He went on exceedingly well for some days. On Wednesday, the 24th, he was most anxious to get up, and on the wound being dressed, union had taken place by the first intention. On Saturday, the 27th, I found him sitting up and dressed; he said he was quite tired of bed. In the evening he sent down, stating he had taken cold. He had some aperient medicine sent him.

On Sunday the symptoms of tetanus became marked; there was considerable rigidity of the muscles of the neck and jaw, and difficulty in swallowing. He had an enema with turpentine, calomel, and an active aperient, which soon operated. The symptoms continuing, he had thirty minims of liquor opii sedativus, every hour, and belladonna to the neck and jaws. He was perfectly under the influence of opium, but without any remission of the symptoms of opisthotonos.

Monday evening. The spasms now most violent. Half a drachm of æther, added to each dose of opium, and calomel freely given through the night.

Tuesday morning. No better, but decidedly worse. We now determined to try æther. This was administered by means of Boott's apparatus. He was soon under its influence, and immediately all contraction and spasm ceased, and he got into a most comfortable sleep, which lasted full ten minutes. As soon as he became sensible the spasm and contraction returned, but scarcely so violent. He again inhaled the æther with the same result. He had it a third time; it again relieved him, and he was left asleep, and on visiting him I found he could open his mouth better. He was most anxious to have it again, but a violent spasm came on before I could get it to him, followed by another, and he immediately sank.

I am, Sir,
Yours truly,
H. H. BROUGHTON.

Dobcross, near Manchester,
Saturday, April 24, 1847.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF WILLIAM SANDS COX, ESQ.

By PETER HINCKES BIRD, one of the Resident Medical Officers.

(*Continued from page* 184.)

CASE XXVII.

EXTENSIVE INJURY OF THE HAND.

Eli Holloway, aged 15, admitted into the Queen's Hospital, on August 24th. He states that about half an hour previously his hand was severely wounded by a circular saw, which cut off the little finger of the right hand, and severely lacerated the two next; he lost but little blood at the time.

When admitted the little finger was found gone, and there was present a deep lacerated wound on the back of the hand, extending from just below the head of the metacarpal bone of the little finger to that of the middle finger; the metacarpal bones of the middle and ring fingers being shattered. He was rather pale; he did not complain of much pain in the parts; pulse 75, pretty strong.

It was determined that the middle and ring fingers should be removed. An incision was made on the back of the hand below the seat of injury; the metacarpal bones were sawn through, and a flap formed from the palm of the hand; there was not much hæmorrhage; the patient bore the operation remarkably well; the stump was dressed, and a roller lightly applied; he

was then put to bed, and ordered to keep the hand damp with a cold lotion.

26th. Doing well; wound discharges healthy matter; not in any pain; sleeps well.

September 1st. Improving; the wound is looking healthy, and heals rapidly.

10th. Healing; looks healthy; appetite good.

17th. Nearly healed; general health improved.

21st. Quite well.

In injuries of the hand no more should be be removed than is absolutely necessary, but in this case the extensive injury would not permit the attempt of saving more than the thumb and fore-finger, which forms a useful but rather an unseemly member. The fore-finger and thumb are much more useful than the other fingers, for indeed all the delicate movements are performed by them, and should therefore, if possible, be saved; there are other fingers to compensate in some measure for the loss of one, but the loss of the thumb can never be supplied.

Case XXVIII.

NECROSIS.

Edward Ferraday, aged 16, of strumous diathesis, zinc-worker, admitted into the Queen's Hospital April 17th, 1846, under the care of Mr. Sands Cox. He states that about nine weeks ago he dropped off from some height, and sprained his ankle, the foot becoming quite numbed at the time; was under medical care, and had leeches and cold lotions applied, and was lanced near the ankle in two places. He states that he felt two pieces of bone loose before he came into the hospital.

Present state.—There is much swelling about the ankle-joint of the right foot; there are also four fistulous openings, with fungous granulations, three on the inner side, and one on the outer; the ends of the tibia and fibula near the ankle-joint appear enlarged, and feel rough; various depressions can also be felt on the upper third of the tibia; the ulcers discharge a thin flaky pus; the motion of the joint is impaired, it causes him but little pain; the skin is red and shining, and painful to the touch; the redness extends half-way up the leg; appetite good; tongue clean; sleeps well. Ordered to have the parts constantly poulticed.

19th. A small piece of bone was removed from one of the openings this morning.

23rd. Since last report two pieces have been discharged, and another wound formed; he feels easier; health improved.

27th. Two pieces of bone have come away since last report, one of them was about an inch and a half long.

30th. Rather better. To have the wounds dressed with simple dressing, with apertures left for the discharge, which is now thick and yellowish; also to have a damp roller loosely applied.

May 1st. The roller caused much inflammation and pain, so that it was obliged to be discontinued; two of the openings have healed, and the rest discharge a thick healthy pus. To continue the poultice.

22nd. Much better; the inflammation extending up the leg has subsided; two fresh wounds have broken out and discharge freely.

June 27th. Since last report fifteen pieces of bone, some of them an inch and a half long, have come away at various times; is in no pain; can walk about; very little inflammation present; health improved.

July 14th. Seven pieces of bone have come away since last report, two of which came from an opening in the upper part of the tibia.

20th. Much better in all respects; no more bone has come away; inflammation subsiding. To be dressed as before; the fungous edges of the wound require to be touched with Argenti Nitras.

August 3rd. The skin again became red and painful. Apply poultice.

September 21st. Since last report as many as twenty pieces of bone have been discharged; the matter is healthy, and the parts not painful; general health good.

28th. He still remains in the hospital.

The tibia is the most frequent seat of necrosis, and this disease is most common from twelve to eighteen years of age. Every bone in the body is subject to necrosis; but those bones which are superfical, and enter into the formation of the extremities, are more frequently affected than others whose situation is deeper. This case is remarkable for the great number of pieces of bone of various sizes which came away at different times, and also for the slight nature of the accident which is said to have been the cause of the disease. The scrofulous constitution of the patient had probably some share in bringing on the disease.

PROVINCIAL

Medical & Surgical Journal.

WEDNESDAY, MAY 5, 1847.

The law has been compared to a net, through the meshes of which little fishes are allowed to escape, and great fishes to break. Such is very certainly the case in respect to that portion of it which relates to questions of medical practice, and though occasionally one of the smaller fry may be caught, as in the instance of the singularly unfortunate individual whose trial is reported in another column, the exceptional occurrence is chiefly remarkable on account of its extreme infrequency, and the difficulty of securing the captive, who after all, will shortly be returned to his original element, doubtless again to follow up his former malpractices, though perhaps with more cunning and caution, so as to escape the consequences. The mischievous part of the matter is that the judicial institutions of the country are not merely set at nought, but are continually brought into contempt, and the public are fleeced by the cupidity, and miserable sufferers in every way from the ignorance and most culpable rashness, of a host of sharpers, of various

descriptions, who are virtually upheld in their depredations by those whose province it is to protect the unwary from all such designing pretenders.

The spirit of quackery is widely extended through all ranks of the community, and for the simple reason, that with all the outcry about the increase of knowledge, the intellectual pabulum afforded by the literature of the day is of the most unsubstantial and trashy description. The wisdom of the nineteenth century is but a wide spread of shallow waters, and accordingly noisy quackery and superficiality of every kind find favour, when the more solid acquirements which result from study and reflection are neither appreciated nor understood. All ranks of the community, as we have said, are more or less imbued with this spirit of quackery; the main difference is, that the altogether ignorant are caught by the grossest delusions of the itinerant mountebank, who parades his worm-nostrums,—his vegetable powders.—his rapid cures in "cases of secresy," &c.; while the so-called educated classes flock in crowds to fashionable hydropathic establishments, or complacently swallow the infinitesmal doses of fashionable homœopathic doctors, together "with the infinite deal of nothing" in the guise of reasoning, with which the absolute inertness of the one system and the dangerous activity of the other are commonly accompanied.

Cases of manslaughter arising out of the practices of quackery, are becoming fearfully frequent; but it would almost seem, that in the ratio of the ignorance and presumption of the offender, are the chances of his escape from punishment. In the case of Flitcroft, though the man was proved to be an ignorant uneducated person, utterly unacquainted with disease, and every way incompetent, and it was shown that two lives had been sacrificed to his incapacity, had the trial been on a charge of manslaughter, he would, in all probability, have escaped—the rights of a corporate body being considered in the eye of the law more worthy of protection than the lives of the unfortunate individuals who were deluded by his pretensions. And had the offender, instead of being absolutely ignorant of medicine, as he was, been the most accomplished physician or surgeon of the age, he would have incurred the same penalties. In the case of Cronin, where the charge was for manslaughter, though poisonous agents of the most active and dangerous character were prescribed, and where in particular, there was, to say the least, a lamentable and most culpable carelessness, in not sufficiently designating a preparation not to be found in the national pharmacopœia, and for which the formulæ given by different authorities, vary greatly in point of strength and activity,* the offender is allowed to escape. Well does one of our contemporaries, in an admirable analysis of the evidence given on this trial† remark, that "this Cronin case has an influence far beyond that which it derives from the pseudo-scientific evidence given on the occasion; that influence extends to the lives of the public, which are, by the result, left at the mercy of all sorts of prescribers and dispensers,—the neglect of the one and the ignorance of the other are not regarded as culpable; and while we are left to infer, that according to that perfection of reason—the law—there was no criminality in this case, no pains are taken by the legislature to prevent the recurrence of instances of a similar kind."

Review.

On the Pathology and Treatment of Scrofula; being the Fothergillian Prize Essay for 1846. By Robert Mortimer Glover, M.D., &c. London, 1846, 8vo, pp. 315. Plates.

From the very extensive analyses which have already appeared of the chapters of this excellent work, which treat of the chemical and microscopical investigations into the nature of *scrofulous* and *tubercular matter*, we shall, in the present notice, devote attention mainly to other points, and more especially to the etiology and treatment of the disease.

Dr. Glover gives a concise, and at the same time, a comprehensive statement of the results arrived at by his fellow labourers in this most interesting field, together with those of his own carefully-conducted investigations and experiments, which entitle him to the greatest credit, both for impartiality and candour. He is a strong advocate for the *identity* of *scrofula* and *tubercle*, as will presently be shown. The analogy existing between them has not been unknown to, or denied by, observant medical men, even prior to the light which chemical analysis and the microscope have thrown upon the subject. Their absolute identity is still, however, a matter requiring farther elucidation, as these means, like morbid anatomy, may be regarded as showing the effects of morbid action, rather than affording information on the nature of such action itself. One thing, however, is certain—viz., that the more intimate our acquaintance with the pathological changes which diseases produce, either in structure or functions, becomes, the more rational also will be the system of therapeutics used for the obviation of such conditions. Dr. Glover's opinion may be at once known by the following brief extract, from pages 25 and 26:—"We adopt, in its fullest extent, the statement of Lugol, which makes scrofula,—*i. e.*, the

actual process of disease,—to be always revealed by the development of tubercles." Did space permit, it would be desirable to examine the arguments which the author, in a true philosophical spirit, has adduced on this part of the question, *pro* and *contra*; this, however, being impracticable, we must reluctantly pass them over. The advocates of the identity of tubercle and scrofula, as already said, rest their views chiefly on the chemical analysis and on the minute structure revealed by the microscope; the first and second chapters which relate to this subject deserve the most attentive perusal and examination.

Chapter III. is devoted to the consideration of the scrofulous diathesis, on which the author makes the following judicious introductory remark:—"A careful distinction should be made between the scrofulous diathesis, or predisposing constitution, and the actual processes of the disease; between the *ens in potentia*, and the *ens in actu*." This chapter, like the preceding, deserves a careful perusal, as in it are given, what are called the characters of the diathesis. Without agreeing in all which it contains, it displays a minute acquintance with the opinions of others, and the capabilities of the author to discriminate and apply them. Here we have the *questio vexata* of complexion discussed, which from long experience we regard as of little moment in a practical point of view, although it is our conviction, that scrofulous disease is most common in the lymphatic temperament, and that this latter is most frequently associated with light colour. Towards the conclusion of the chapter we meet with the following paragraph:—"We agree entirely with Mr. Phillips in assigning the 'Strumous Dyspepsia' of Dr. Todd, when present, rather to the actual disease than to the diathesis. Neither are these symptoms of dyspepsia confined to cases of tubercular deposit." Our reason for noticing this statement is, that we have been long convinced of the influence exerted by derangement of the digestive functions in *absolutely* inducing scrofula in children, who had, previously to the operation of such cause, possesessd not merely the appearance of a sound and healthy constitution, but enjoyed even robust health. This remark applies with peculiar force to the dyspepsia which is so constant a concomitant of teething, and which is but too frequently aggravated by the medical treatment adopted for its relief, more especially by the unnecessary exhibition of calomel. To this source of scrofulous disease we think our author hardly attaches the importance which it fairly claims

Chapter V. is devoted to the "Identity of Scrofulous and Tubercular Diseases." Into the examination of this our limits forbid us to enter, in a manner at all commensurate with the importance of the question, and therefore we are obliged to pass on to Chapter VI., which treats of the "Essential Nature of Scrofula." After objecting to various definitions of the disease, Dr. Glover says,—"Scrofula is a"———"peculiar modification of inflammation, whereby the usual, or, as they may be termed, the normal products of this process are not evolved; but instead of them, other materials, incapable of passing into regular cell-forms, and which constitute the substance already described under the name of scrofulous or tuberculous matter. The peculiarities of this formation, and the continuance of the scrofulous diathesis, are the causes of the characters assumed by the various after-processes which result from the existence of tubercle." This definition is, we conceive, to say the least of it, open to very great discussion. As however constant a degree of inflammation may be as an attendant on scrofula, we can hardly see the grounds upon which such action is to be regarded even as an essential element of the disease. Dr. Glover ably discusses this question, but, after a careful perusal of his arguments, we are still inclined to question the *inflammatory origin* and *nature* of scrofula. When this remark is made, it is right to state, that we are perfectly aware of the fact, that both scrofulous disease and tubercle of the lungs do frequently arise as a consequence of inflammation, and that both are very generally accompanied by it, in one form or other, in their progress to maturity; this however, does not, in our estimation, in any measure warrant the conclusion, that either scrofula or tubercle is of necessity essentially inflammatory in its origin. In confirmatiou of his views on this question, Dr. Glover quotes Dr. Bennett's ideas on inflammation. We do not, however, consider the light thrown upon the subject, either by microscopic examination or chemical analysis, sufficiently powerful to overthrow all that has been so long received, and it may be said sanctioned, by careful physiological and pathological observers. As we have already said, chemical analysis and the minute structure developed by the microscope, make us acquainted with results, but the cause of these is not demonstrable, either by one or other of these agents. If confirmation of this be required, reference may be made to the analyses of both the blood and urine, as given in the work before us, from which it will be seen that literally nothing is proved at all peculiar either to scrofula or tubercle; the changes or deviations from the healthy state of these fluids, being met with in cases of disease, and conditions of the system, in nowise allied either to tubercle or scrofula.

Chapter VII is devoted to the "Etiology or Scrofula." In it the question of hereditary influence is fully and ably discussed by our author, who has given several cases in illustration of the subject, and which decidediy favour the generally-received opinions on this point. Dr. Glover has not contented himself with merely examining into the history of the parents, but has extended his inquiries to the collateral branches of their families. From these cases it appears, that even

where the parents were healthy, other members of the families suffered from either phthisis or scrofula. The subject in case No. 3, had an epileptic sister, this we notice, as in several instances which are vivid in our recollection, we have observed the occurrence of epilepsy and scrofula in the same families. How far these diseases really are associated or connected, may perhaps deserve attention. The same remark applies to hydrocephalus, which is mentioned as having occurred in the family of Case 5. The following remark will carry the assent of most practical men:—"But although the hereditary nature of scrofula be established sufficiently, questions remain with regard to the degree of influence in the causation of the disease, attributable to hereditary influence, and to what may be termed occasional causes, both pathological and external."

Of the occasional causes of the disease, Dr. Glover adopts the following division, and on each section makes many judicious observations, through which, however, space does not permit of our following him:—

"1st. Bad air and defective ventilation.

"2nd. Confinement and want of exercise.

"3rd. Imperfect nutriment and exposure to cold and wet.

"4th. Venereal errors.

"5th. The influence of other diseases, called by Lugol pathological causes.

"6th. The influence of climate, of age, and sex."

Chapter VIII treats of the localization, modifications, and complications of scrofula

The second part of the work is dedicated to the consideration of the treatment of the disease, and contains a very good digest of the various remedies now in use. In regard to mercury, Dr. Glover well observes,—"The total proscription of mercury is as unwarrantable as the exclusive use of iodine or cod-liver oil," in which remark we most perfectly concur. Of the mercurials, we also agree with the author, that the Hydrargyrum cum Creta is the best and safest preparation. His remarks on the various remedies are judicious, and display a thorough knowledge of both the physiological and chemical operation by which they are characterized, especially as regards the compounds of bromine and iodine. We have only space for a very brief notice of his remarks on cod-liver oil, of which he describes three varieties, for the description of which we must refer to pages 271-2. Dr. Glover used the second variety. He states that "the effects of cod-liver oil have been attributed to its iodine, and also to its bromine," and farther observes,—"When cod-liver oil is taken internally, no odour can be perceived in the secretions and excretions; and in Case 1, of the analyses of urine, we obtained it, or a quantity of oil, at least, from this fluid." Applied externally it appears to be absorbed through the skin, in illustration of which, Klencke's experiment on two dogs is cited, according to whom, the oil should not be given to plethoric people, or to very young children. For its therapeutic action, *vide* pages 243-4, wherein it is stated, that "the action of cod-liver oil is, in all probability, as a tonic, from the resinous principle which it contains, by stimulating animal heat, occasionally by acting as an aperient, and also as a deobstruent, more particularly by increasing the quantity of urine." Klencke supposes "its usefulness to be owing to its supplying the deficiency of the fatty principles of the bile, which, according to him, are not excreted in sufficient quantity in scrofula, but remain in the organ, constituting the fatty liver so often found in this disease."

The plates at the end of the work are well calculated to illustrate the changes to which they relate, and are exceedingly well executed. We must now conclude this notice of a most interesting work. In doing so, we congratulate the author on the manner in which he has performed his task, and cordially recommend it to our professional brethren.

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

February 6th, 1847,

ALFRED BAKER, Esq., in the Chair.

OVARIAN TUMOUR: COLLOID DISEASE OF THE LIVER.

Dr. Fletcher exhibited a large right ovary, which weighed ten pounds, attached to the uterus, and a portion of the liver taken from the same subject, affected with colloid disease.

In the commencement of May, 1846, being in attendance upon a sister I was consulted by Miss S., a young lady, 23 years of age, who had slight general emaciation, and had increased uncomfortably in the bowels; the stomach seemed in a tolerably healthy state; the functions generally were performed well; the pulse was about 75, rather feeble; menstruation was regular, but deficient in quantity. She did not think the state of her health at all alarming and only complained of the size of her bowels. She was engaged to be married in a few months.

I requested to be allowed to make a more particular examination than her dress permitted. This was instantly acceded to, and I then found a tumour in the lower part of the abdomen, exactly in the median line, extending from the os pubis up to near the umbilicus, smooth and rounded in its form, and elastic to the touch, and fully representing a gravid uterus at between the fifth and sixth month of pregnancy. On examining per vaginam, the os and cervix of the uterus was found in a virgin state; the uterus was fixed and somewhat retroverted in its position, the os and cervix lying forward under the os pubis, and the fundus backwards, so that the inferior portion of the back of the uterus could be felt without difficulty, and on this portion a small tuberculous nipple-like projection was felt. From this examination it was evident that there was a tumour in

the abdomen, and the fixed state and position of the uterus, and the existence of a small body upon its posterior surface, lead somewhat to the conclusion that the tumour was attached to the uterus. The application of iodine externally and internally was the treatment employed, and attending to the general health.

About three weeks afterwards, the patient beginning to get thinner and increasing in size in the abdomen, by an examination, instead of one single tumour being found, it appeared to have split into several, which lay in two masses on either side of the median line,—that on the right extending up towards the liver, that on the left not quite so much external, but larger than the other. An examination per vaginam detected the uterus itself in the same state, but higher up in its natural position, and not fixed; it moved freely by pressure of the finger. It was now quite evident that the tumours were ovarian, and that the uterus was not greatly implicated in the disease.

The patient from this time got rapidly worse, emaciation and debility increased, and the tumours rapidly grew larger. That on the right side could be felt knotty and hard, and extended up to the right hypochondrium, so that in a month after the last examination described, when Mr. Hodgson kindly saw the case, it was impossible from examination, to say that the tumours were not connected with the liver. The tumour on the left side seemed to extend more laterally and not quite so high as that on the right, and was felt in hard lumps all over the left side of the abdomen. Anteriorly and below, between the lumpy projections, fluctuation could be detected; and in the upper part and in the lumbar regions the sound was tympanitic upon percussion. Mr. Hodgson recommended iodine to be *pushed* even more extensively than it had been, which was continued for some time.

The future state of the patient can only be described as getting worse and worse; emaciation went on without interruption; the tumours increased in size. At times there was difficulty in passing motions or urine; at times there were slight pains in different parts of the abdomen, more particularly in the right inguinal region, but these were never severe in their character, and readily gave way to fomentations and leeches, and after extreme emaciation, she died on the 29th of January, 1847.

Post-mortem examination, January 30th, twenty hours after death. The body in the utmost state of emaciation; abdomen hard and much enlarged, measured three feet six inches round over the navel, and one foot nine inches from the os pubis to the ensiform cartilage.

The head was not examined. The contents of the thorax were free from disease. The integuments of the abdomen were very much distended. On opening the abdomen, about a gallon of fluid escaped from the cavity of the peritoneum, of a brown colour, and turbid. On examining it, it slightly reddened litmus paper, was 1.020 in specific gravity, and very highly coagulable on boiling. The peritoneum was thicker than normal, and was covered by a thick semi-transparent gelatinous substance, which, on examination under the microscope, exhibited the characters of fibrin, which, most probably, in the process of coagulation, had separated from the fluid. The whole cavity of the abdomen was occupied by the ovaries, which had increased to an immense size; the right one (the one produced,) was rather longer than the left, but not more than half its bulk; it weighed ten pounds, and was composed of cells of different kinds; some were cysts, and contained fluid, (which of course escaped upon being punctured,) others contained a soft substance, having the yellow semi-transparent appearance of colloid matter, whilst other nodules were composed of a hard cartilaginous substance; the two latter, examined under the microscope, exhibited the nucleated cells of malignant disease. There was a small nodule of tubercle, which projected at the posterior part of the neck of the uterus. The liver exhibited nodules of colloid matter, which had the same appearance under the microscope as the portion taken from the ovary. The spleen and pancreas were healthy. The intestines were healthy, but contracted, with the exception of their peritoneal coat, which was rather thickened, and they were covered generally with coagulated fibrin. The kidneys were healthy, but the pelvis and upper portions of the ureters were distended.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

February 22, 1847.

ÆTHER-INHALATION.

M. Flourens read a notice respecting the influence of æther on the medulla oblongata. He remarked that he had previously ascertained that in the spinal marrow sensation was abolished before motion, but that both might be destroyed without destroying the life of the animal. The explanation of this is sought in the following experiment:—

A dog being fully brought under the influence of æther, the medulla oblongata and spinalis were laid bare. Pricking the latter in both its anterior and posterior columns gave rise to no movement on the part of the animal. This point being clearly ascertained, the medulla oblongata was irritated, when the animal uttered a loud cry, and the muscles of the neck were seen to contract. The same phenomena were elicited in two similar experiments, from which M. Flourens draws the conclusion that the different portions of the nervous system are successively influenced by the æther, and that the medulla oblongata is the last in the series.

The same physiologist has made trial of other æthers, as the chloric and nitric, the former of which exhibited an action precisely similar to the sulphuric. In three experiments with the latter the animal was destroyed (?) in the space of two minutes.

[The French word *succomber* is generally employed with the signification of death, but possibly the experimenter here uses it to express insensibility; we do not believe that death would be produced in the short period mentioned, as we have inhaled pure nitric

æther, certainly not without a remarkable feeling of thoracic inconvenience, not experienced from the use of sulphuric æther, but without any symptoms which would lead us to expect such rapidly fatal effects. Transl.]

The inhalation of alcohol did not produce any insensibility, but only intoxication. M. Flourens sums up as follows:—1. The action of the æther upon the nervous centres is successive and progressive. 2. The cerebral lobes are first influenced; next the cerebellum, then the spinal marrow, and last of all, the medulla oblongata.

M. Laugier related several additional operations under æther, and stated that he had particularly remarked, that the colour of the arterial blood was not altered, as has been represented.

M. Gerdy observed that he did not consider it necessary to produce entire insensibility, as he had found patients bear operations without manifestation of pain, in whom the ætherization had only produced slight stupefaction.

M. Landouzy related his experiments to determine the combustibility of expired æther, from which it appears that all fear of explosion may be discarded.

M. Ducros suggested that the effects of æther may be immediately dissipated by galvanism.

REAL AND APPARENT DEATH.

M. Mandl made known a means of distinguishing real from apparent death, which consists in noting the effects of a burn upon the integuments. The results obtained by M. Mandl are the following:—

1. A burn of the second degree produces vesication in the living subject.

2. This does not take place in the dead body.

3. The author does not venture to state that vesication takes place in all individuals, and in every form of disease.

M. Serres, in connection with the above communication lamented that there was no certain sign of death, a point of much consequence in many cases, as for instance, where the propriety of the Cæsarean operation becomes a question, and he in consequence proposed a commission to enquire into the merit of the proposed test.

March 8th.

M. Flourens read a second memoir upon the physiological action of æther, in which he exhibited its close affinity to asphyxia.

M. Roux related a case of tetanus, in which he considered that the fatal event was decidedly hastened by the inhalation of æther.

ANALYSIS OF THE BLOOD AFTER INHALATION OF ÆTHER.

M. Lassaigne communicated the results of an examination of the venous blood of an animal before and after inhalation. The following is a summary of his observations:—

1. The blood taken before and after inhalation did not differ sensibly in colour, nor as to coagulation; that taken after inhaling exhaled a strong odour of æther.

2. The serum and clot in the two specimens of blood differed as below:—

Before inhaling	Clot	65.46
	Serum	34.54
		100.00
After ditto	Clot	59.69
	Serum	40.31

3. After inhaling, the serum acquires a slight reddish tinge.

4. The clot appears less consistent before than after inhaling.

5. The globules, fibrin, and the albumen, preserve the same proportions after as before inhalation.

6. The quantity of æther absorbed by the blood is inappreciable in the small quantity of blood submitted to examination. We have, however, endeavoured to ascertain this quantity by studying comparatively under the same thermometric and barometric conditions the tension of the serum before and after inhalation, comparing the result with the tension of a solution of æther of a known strength. By this means we believe that we are authorized in estimating the quantity of æther absorbed, as 0.0008 of the quantity of the venous blood.

INFLUENCE OF ÆTHER ON THE CIRCULATION.

M. Amussat repeated his conviction that the physiological effect of æther was a veritable asphyxia; he also stated that the blood is rendered more fluid and less coagulable. The latter circumstance he regarded as important in reference to secondary hæmorrhage.

ÆTHER AS A MEANS OF DETECTING FEIGNED DISEASES.

A novel application of this agent has been suggested by M. Baudens,—namely, that of detecting malingering. Two cases are related, one of feigned spinal curvature, the other presumed feigned anchylosis of the hip, both in soldiers. In the first case the dorsal deformity totally disappeared during the æthereal insensibility; in the other the immobility of the joint remained, and was thereby proved to be real.

CHEMICAL COMPOSITION OF OSTEO-SARCOMA.

M. Roux, desirous of ascertaining the composition of this form of tumour, analysed a specimen removed from the humerus. It was found to consist of the following ingredients:—

Water	87.86
Chondrine	0.85
Albumen	0.30
Margarine, stearine	0.28
Carbonate of lime	0.67
Phosphate of lime	0.59
Sulphates of soda and potass	0.28
Carbonate of soda	0.14

Sulphate of magnesia, silica, &c.,—a trace.

SIGNS OF APPARENT DEATH.

M. Levy claimed the priority of discovery of vesication after burning as a test of real and apparent death.

M. Bouchut related some experiments entirely

subversive of the credibility of this test, having succeeded in raising a perfect vesication in four corpses.

[The reader may recollect some experiments on the same subject by M. Champonillon, (*Prov. Journal*, Jan. 27, 1847.,) which are strictly in accordance with those related by M. Bouchut.]

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE.

February 23, 1847.

The claims of Mr. Wells to priority in the application of æther-inhalation having been discussed, the meeting proceeded to the consideration of the employment of the extract of nux vomica in chorea, which formed the subject of a memoir, by M. Trousseau, and was reported upon by M. Gaultier de Claubry.

ÆTHER-INHALATION IN OBSTETRICAL PRACTICE.

M. Dubois observed, that although what he had to bring before the meeting was to a certain extent connected with the subject of previous discussions, he yet considered that he should adduce much that was new and important. M. Velpeau and M. Bouvier had been the first to express the surmise that the stupefying effects of æther might be made available, in removing the pains attendant upon parturition, but the speaker was the first [in France. *Transl.*,] to put the practice to the test. His objects in his experimentations were to assure himself in the first place, that the æther was inoffensive to the mother and child, and also to learn the action would not extend itself to the muscles of the uterus, and so destroy its contractility. In illustration of his investigations, he narrated the following cases:—

A female, aged 18, primiparous, exhibited no sensation of pain while the forceps was applied. In a second and similar case, the same insensibility was observed.

In reply to the question whether æther has the power of abolishing the contractility of the uterus, and the abdominal muscles, he related the subjoined cases:—

A female who had been in labour with her first child for two hours, was the subject of regular and severe pains. Inhalation produced certain unpleasant phenomena, such as determination to the head, injection of the eyes, stertorous breathing, &c., but, nevertheless, the contractions of the womb were not affected, and took place without the slightest consciousness on the part of the patient. During the insensibility, the pulsations of the fœtal heart were distinctly perceptible, but appeared to diminish in frequency as the insensibility of the mother became more profound.

In another female, who cried out loudly under the severity of her pains, æther produced complete insensibility in three minutes; during this period the uterine contractions continued with their usual vigour, but gave rise to no expression of pain on the part of the patient. In this state the child was expelled, and on recovering her senses, the patient declared that she had been perfectly unconscious of suffering.

The conclusions stated by M. Dubois, as arising out of his experiments, are,—that æther has the power of subduing pain in obstetrical operations; that it suspends the natural pains of labour in a most marked manner; but, on the other hand, that it does not suspend either the contractions of the womb, or of the abdominal muscles. In answer to the question put by some of the members, M. Dubois further stated that he had not observed that any ill effect was produced upon the child by the inhalation.

March 2nd.

ON CATHETERISM IN STRICTURES OF THE ŒSOPHAGUS.

This was the title of a memoir by M. Trousseau, having for its object the recommendation of graduated probangs in the treatment of constriction of the œsophagus. In the discussion which ensued, M. Gerdy remarked that there was nothing novel in the treatment, and related a case in which he had succeeded in restoring the calibre of the passage, after it had been so far reduced as to admit an urethral sound with difficulty. M. Cloquet observed that great discrimination was necessary as to the nature of the obstruction, in cases in which this mode of treatment was proposed. It was spoken of by Velpeau as of great value in spasmodic and simple inflammatory strictures.

March 9th.

ÆTHER-INHALATION DURING LABOUR.

M. Bouvier related the following case:—A female, aged 26, entered the Hospital Beaujon, having been in labour for five or six hours. The uterine contractions were rapid; the os uteri dilated to three centimeters; the membranes projecting; and the cervix obliterated, firm, and resisting. The pains being extremely violent, the patient inhaled æther. At the expiration of eight minutes she became insensible, and from *that moment the uterine contractions ceased*, but recommenced on her recovery. As M. Bouvier observed, this case is directly opposed in its result to those of Dubois and Simpson, both of whom mention that the uterine pains are not influenced by the agent.

In remarking on this case, M. Roux enquired whether the intermission of the pains was not accidental, and unconnected with the inhalation, and alluded to the naturally intermittent character of the uterine contractions.

March 16th.

After the reading of a commission of inquiry on several different methods of embalming, M. Dubois presented a specimen of

SPONTANEOUS AMPUTATION IN THE FŒTUS

The infant had been born two days. The middle and ring finger of the left hand had lost the upper phalanx, as had also two toes on each foot. The extremity both of the fingers and toes exhibited a sort of wound still bloody, thus attesting the recent removal of the parts. In addition to these accidents, the left leg presented a deep circular depression similar to that produced by a ligature. The same appearance in a greater degree existed also in the right leg. At the time of birth the amputated parts did not shew any traces of irritation, but have since become inflamed. The umbilical cord was not more than half its usual length, but the placenta was normal. M. Dubois proposed to make some observations on this case at a future meeting.

THE NATIONAL INSTITUTE OF MEDICINE, SURGERY, AND MIDWIFERY.

On Tuesday, the 13th instant, a conversazione of the members of the National Institute of Medicine, Surgery, and Midwifery, was held at the Hanover Square Rooms, which was attended by a numerous assemblage of both metropolitan and provincial members.

For the gratification of the gentlemen present on the occasion, the Council had invited collections of subjects of great curiosity, interest, and value, which were displayed on tables down the middle of the great room. Among these were instruments for the inhalation of æther and of oxygen; admirable models of pathological subjects, after the invention of Dr. Thibert; a great many specimens of articles of the Materia Medica, remarkable for purity and superiority of quality and character; and there was a collection of engravings and curious objects of *virtu*, referring to the archæology of medicine, the property of G. J. Squibb, Esq., this collection, comprising the largest number of engraved portraits of eminent medical men of all ages and countries which is known to exist.

Mr. Ward, of Wellclose Square, exhibited many natural curiosities, and also one of his close cases for the culture of plants, and kindly gave a short history of his discovery of this most agreeable and useful adjunct to the cultivation and preservation of plants, in an atmosphere so unfavourable as that of the metropolis, and also as respects great diversities of temperature.

Mr. Ward, after citing the elegant hypothetical description of the physical peculiarities of climate in paradise, from the writings of Guernerus Rolfincius, a professor at Jena, 1669, (*"Nulla ibi immodica ventorum vis, nulla tempestatum procella, nullus horror, non torrens æstatis ardor, non molesta et noxia antermin siccitas; sid temperata et pacifica omnium temporum cieter se consonantia,"*) stated that, supposing the description to be probable, it was not unreasonable to conclude, that the atmosphere and climate of his case might be nearly those of paradise itself.

Following up the analogy, Mr. Ward did not doubt that apartments for human habitation might be similarly adapted for the occupation of invalids suffering from pulmonary and cutaneous diseases, mentioning the instance of a lady who, having been ordered to a warmer climate, from circumstances being unable as well as unwilling to leave home, rooms were adapted for her use on this principle, in which, after living for one or two years, she was perfectly restored to health.

In the course of the evening Mr. Pennington, the venerable and highly-respected President of the Institute, delivered the following address:—

"Gentlemen,—After difficulties innumerable, we have at length arrived at a period in the history of the National Institute which I trust will be an evidence of two things:—1st; That as a class we are determined to sustain our position, and to assert with becoming dignity our right to be considered one of the scientific bodies of the kingdom, and an essential part of the medical profession:—2nd; That as general practitioners, hitherto in possesion of no means of social communion, we are resolved to furnish them for ourselves, and no longer to be solely dependent upon the courtesy of other bodies.

"I have been sixty years a member of the College of Surgeons. I believe that I am the oldest member of that body, and I fearlessly assert that no man has had better opportunities of judging than I have respecting all that is connected with our profession, and of the various relations of that profession to the public. My intercourse with every order of medical practitioners during this long series of years, and my enjoyment, I may fairly say, of a very considerable share of the public confidence, has afforded me means more extensive than has fallen to the lot of any other individual, not only of judging what the medical requirements of the community are, but also of the capabilities of every description of medical practitioner.

"You are all aware, gentlemen, that during the whole of my life I have practised as a general practitioner. Cullen, William Hunter, Jenner, and Abercrombie, were general practitioners, and we have a right to feel proud of the memory of such names. Throughout the lengthened period to which I have referred, I have had the most complete demonstration, that the confidence reposed by the public in the competency and skill of the general practitioner has been well merited, and that the principles upon which the general practitioner stands are those of truth and justice; and my connection with the National Association and the National Institute has assured me, that this confidence not only continues, but is on the increase, and that I and others who must soon pass from the scene, will be followed by gentlemen who will equally enjoy it, and who in the progressive advancement of practical medical and surgical science, will fully sustain the character and the honour of their class.

"Identified as I have been with this class—impressed with the most thorough conviction that the welfare of the community depends upon its prosperity—observing its progressive advancement in knowledge and respectability—it has for many years been a source of deep regret to me, that so large and intelligent a body, embracing as it does so much sterling worth, should be deprived of the advantages which would result to themselves, to science, and to the public, from their association into an effective and permanent body; by which association only, can they take their stand as one of the recognized Medical Institutions of the country.

"My energies have ever been directed to the attainment of this object. I took an active part during the agitation of the years 1812, 1813, 1814, and 1815. With this object in view, I hailed with satisfaction the attainment of the Act of 1815. Defective as it was, the Act gave to the general practitioner the power of educating himself up to the standard which his important functions demanded. From that time to the present, and totally apart from any bill introduced by any minister, I have never failed to advocate THE INCORPORATION OF THE GENERAL PRACTITIONERS,

and the retaining this power in their own hands, and extending and perpetuating this important privilege. It was the contemplated abrogation of this privilege, and the tendency to lower the social and professional position of the general practitioner, and thereby to inflict a serious injury upon my fellow-creatures, in the change recently adopted by the College of Surgeons, and in the medical legislation recently attempted, which induced me, at my advanced period of life, again to take an active part in asserting the claims to consideration of the class to which I belong.

"Personally I have no interest in the matter. My comfort and convenience would have been better consulted by ease and retirement—taking no part whatever in political agitation. Still, I by no means regret the part I *have* taken, and I here again declare my unflinching determination to do all that lies in my power, by every means that can be suggested, and to the latest day of my life, to accomplish the object which we have so much at heart, an object which, in my mind, involves the security and happiness of the whole community. At the same time I should not be doing you justice if I hesitated to express my deep regret and great disappointment, at the apathy, distrust, and lukewarm spirit, with which the profession has regarded objects so highly important both to themselves and the community; and that out of a body numbering perhaps 12 or 15,000 individuals, only 4000 have as yet been found public spirited enough to enrol their names as opponents of a scheme of legislation based upon the most erroneous principles, while a still smaller number have come forward to co-operate actively to promote a just and beneficial measure of MEDICAL REFORM.

"Notwithstanding all this, I live in hope of better things. The National Institute will try and carry through its plans in the face of every discouragement or difficulty which may present itself. It is contemplated immediately to take a house, as a permanent abode. The representative council will be annually renewed,—we shall hold our general, our scientific, and our social meetings,—we have already commenced a collection of books, and a large and valuable library will be doubtless formed with great rapidity,—a museum will be the next object of our solicitude; and I trust, that before long, we shall be enabled to give *substantial* encouragement to the members of the Institute for contributions to science. A great object of the present meeting has been to bring together the PROVINCIAL and the METROPOLITAN MEMBERS, that they may have the opportunity of communing freely with each other upon all these subjects, and upon any and every other subject which may bear upon their political and social welfare, and for the especial purpose of promoting the greatest desideratum of all—a mutual good understanding.

"I have not deemed it right, gentlemen, to occupy your time upon the present occasion by any lengthy address; but I was anxious to avail myself of the opportunity, to make my own views and my own determination well understood, and for that purpose I have had these few observations printed, that any gentlemen who desire it may have copies for themselves, or for those friends who are not present, and that no misapprehension may arise from any imperfection in my delivery. I will conclude by stating, that upon this first occasion the Council has laboured under great disadvantages, owing to our not having rooms of our own; but for the purpose of shewing what the nature of our social meetings will be, they have hastily collected together a few objects of interest. I hope every one present will pass the evening agreeably, and to the advantage of the cause in which we are engaged, and I trust that we shall separate with a renewed determination to employ our utmost zeal and energy to promote the successful issue of the cause."

The conclusion of this address was followed by the unanimous expression of warm applause, and a resolution of thanks was carried by acclamation.

The usual refreshments were at hand in the adjoining room. All appeared to enjoy the utmost satisfaction in the proceedings of the evening, and separated with an assured confidence in the expectation of the pleasure of similar re-unions at future times, with improved and enlarged appliances, and means of social and intellectual enjoyment.

CHARGE OF UNLAWFULLY PRACTISING AS AN APOTHECARY: CONVICTION.

An important trial on a charge of unlawfully practising as an apothecary took place at the Bolton Quarter Sessions before the Recorder in the early part of last month. The offender, Ellis Flitcroft, appears to have been somewhat changeable, as he originally commenced the active business of life as a brick-setter, then became a policeman, then returned to his original occupation, ultimately taking up with the trade of agent and assistant to an American herbalist, and occasionally it seems doing a little business on his own acconnt, so far at least as to bring him within the limits of the Apothecaries' Act.

The following is the evidence brought forward on the part of the prosecution, as reported in the *Bolton Chronicle*, and on which a conviction took place:—

Lettice, wife of Thomas Bartley, stated: On the 7th of December last, my son, Robert, was ill. I know Ellis Flitcroft; I went to him on Tuesday morning, the 8th of December, at his own house. I told him that my child was poorly. He asked me how it was; I said it was very red in its cheeks. He said his child would have been in its grave but for some stuff he called Coffin's medicine. He said if the child was red in its cheeks it must be the scarlet fever. I told him my mother had three children poorly. He sold me 1½d. worth of raspberry leaves; he said I must get one pennyworth of penny royal, mix them together, and pour boiling water upon them. He came the same day to my mother's house, where the child was. He brought a powder with him. He called for boiling water, but he mixed the powder up in some cold water, and gave it to the child as well as he could. He said it was to make it "sweat." My mother gave the other to her child. He gave me a bottle of stuff; it was not so "terrible" strong; it was dark-coloured. He said it was intended to make it sick. I gave it to the child until half-

past seven at night; it became sick, but could not vomit. He came at the dinner time and put a bottle of water to its feet and one to its back, after he had given it the powder. After eight o'clock the same night I went to his house. I got something from his wife. He came the next day, between two and three o'clock. He did not bring any stuff with him. I gave the child the stuff I got from his wife, and when he came he told me to give it it every hour. The child grew worse. I went to his house on the Friday. He gave me some more to make it vomit. My father gave Mr. Denham the stuff that was in the bottle, which was produced at the inquest. On the Friday the defendant charged me 1s. 9d. for the stuff. My child died on the day following, Saturday.

Alice Grundy, the mother of the last witness, deposed: I saw the powder which the defendant brought to my house. I had three children ill of scarlet fever. The defendant looked at them, and said that, if we did not take care, one of them would go off in a decline. He said he would engage them for half-a-crown each, but I did not approve of it. There was some of the powder left; he said it would do it no harm, and I gave it the child, who cried and said "Mother its burning my throat." She was red in the face before, but she went more red. I afterwards went to the Dispensary, and my children are all well.

Cross-examined: The defendant is known in Bolton as the agent of Dr. Coffin, a herb doctor.

Susannah Greenhalgh said: My husband (George Greenhalgh,) was aged 25 years. He died on the 16th of January. He gave up work on the 7th January (Thursday,) on account of being poorly. The day after he brought home a bottle of stuff. He took a portion of it every three hours. He thought it did him good at first; he thought so till Tuesday. He was bedfast on Wednesday morning. He then sent me for Flitcroft. He (Flitcroft,) came and saw him in bed. He ordered hot water to his feet, and a vinegar cloth. He desired me to go to his house for some medicine, which was to sweat him, "pick" him, and purge him. I went to his house and received two powders; one of them was green, and the other buff. He charged me 4d. for them. He said I must take nearly a teaspoonful of the green powder, and mix it with warm water and sugar in a cup. He said it was to sweat him. I was to put two teaspoonfuls of the orange powder into a gill and a noggin of warm water, in a pint jug. I was to give him not quite a teacupful every twenty minutes. I gave it him together till he would not have it any more. He got worse, and died on the Saturday. Margaret Rogerson gave some of the powders to Finnigan, the police officer.

Cross-examined. For a day or two at first my husband thought he was better from the medicine. He went out two or three times. Flitcroft told him he was unfit for work. He went to his work on the following Tuesday, and could only work three-quarters of a day. He was worse on Tuesday night. Flitcroft said he had got cold.

Margaret Rogerson deposed: I saw Greenhalgh in bed on the Thursday before he died; he appeared to be in great pain; he complained of being thirsty, and called for water, by quarts at once. I remained with him during the night. I gave the powders to Finnigan, the police-officer.

Ann Leach: I was about two months since afflicted with the rheumatism. I sent for Flitcroft, and he sent me some medicine,—a powder and a bottle. I took a little of the powder, which felt very warm; and afterwards I took the whole powder. I only took one glass of the bottle. I asked the price of the bottle and powder. He said I must never mind it, there was something between my master and him. He owed him something for ale.

Cross-examined. I got better of my rheumatism, but not before I applied to Mr. Chadwick; I think he set me up. I am in the habit of passing Flitcroft's place. He has a sign over his door, which says,—"Ellis Flitcroft, vender of herbs from America; licensed to sell tea and coffee." I have heard them say he was acting under Dr. Coffin's prescription.

Martin Finnigan: I am acquainted with Flitcroft. I first knew him when he joined the police-force, five or six years ago. I know him to be a brick-setter. I received from Margaret Rogerson some powders, which I delivered to Mr. Taylor, the coroner. I have been in Flitcroft's place; I saw a quantity of bottles, of all sizes.

Cross-examined: I was instructed by Mr. Taylor to inquire into this matter, in consequence of two inquisitions. I am the coroner's officer. I collected the whole of the evidence for the inquisitions, except that of Mrs. Leach. I never endeavoured to get up a case. I appeared before the Magistrates to apply for a warrant in this case.

Thomas Mewburn: I apprehended defendant on the 28th of January on this charge. I read over the warrant to him; he said he had no certificate—he did not require any, and that he was not an apothecary, as he dealt in nothing but herbs and plants.

J. Taylor, Esq., solicitor: I am coroner of the borough. In the course of my official duties two powders were given to me by Finnigan. Those are the same that have been submitted to Mr. Denham.

Joseph Denham, Esq., deposed. I am a surgeon and apothecary in this town. By direction of the coroner, I made a *post-mortem* examination of the body of the child Robert Bartley, who had died of inflammation of the lungs. It was a medical case. I have examined the powders produced. The green one is Lobelia, sometimes vulgarly called "Indian tobacco." It is one of the medicines in the Materia Medica. It operates as an emetic; in large doses as a purgative. In very large doses it acts as a powerful narcotic poison. I should say it is likely to be injurious when it does not produce vomiting. The other powder, the buff one, consists of cayenne pepper and spices. It is a stimulant, and would produce a warming effect. In my opinion it would be injurious to a person labouring under inflammation, and improper for a child of the age of Robert Bartley under any circumstances. It is in the Materia Medica. I should say it would produce great thirst; that is its natural effect.

Cross-examined: Cayenne pepper acts as a stimulant. The smallest dose, say a grain, or half a grain, would produce an increase in the circulating powers of a child. It might be a proper medicine to administer in cases of great debility. The other powder is known as Lobelia inflata. To the best of my recollection it was not in the Pharmacopœia of 1819; but capsicum, which is also

called cayenne pepper, was. Lobelia is a vegetable production. It is a description of tobacco. I believe it grows in America. Druggists are in the habit of selling cayenne pepper lozenges, and many kinds of medicinal preparations. Cayenne pepper may be had from grocers, as well as cinnamon. I am not aware that Lobelia is sold by druggists or grocers.

Re-examined: A great number of medicines are vegetable preparations. Rhubarb, opium, and prussic acid are such. Druggists sell medicines when parties come to ask for them, but it is no part of their business to go out and prescribe medicines.

The case was opened by Mr. Brandt and defended by Mr. Sowler, whose arguments went rather to show that the venders of quack medicines in general rendered themselves liable to the penalties of the Apothecaries' Act, than that his client had escaped the infringement of it. A witness was called for the defence, from whom, however, nothing material was elicited, and Mr. Brandt having replied, the Recorder summed up at some length, giving it as his opinion, that the acts named in the evidence, said to have been done by the defendant, were practising as an apothecary, and the Jury, after consulting together for some time returned a verdict of guilty. The defendant was then ordered into custody and sentenced to one month's imprisonment.

MR. CRONIN'S CASE.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Without examining the *very unusual "prescription"* produced at the inquiry into this case, for the purpose of showing how far it is compatible in a chemical point of view, and without arguing how far the "Art of Prescribing" is therein studied, taking the composition as a whole, surely there can be no objection in showing what the different articles so much doubted or questioned are.

I give the prescription as copied from the *Times* newspaper, and of course as a copy I am not responsible for its being a correct transcript of Mr. Cronin's latinity, nor for any other errors or omissions which may be found in it:—

"R. Spt. Ammon. Aromat.	dr. ij.
Tinct. Opii	gtt. xvj.
Acidi Prussici, viz., (Scheele's strength,)	gtt. iv.
Pulv. Strych. Comp.	gr. ij.
Aquæ Amygd. Amar.	oz. vj.

M. Fiat Mist. e qua *sumatur* coch ij. ter die.

"Feb. 3, 1847, Miss Collier,

"D. C."

The subjoined formulæ have been given for the Aqua Amygdalarum Amarum:—

"Aqua Amygdalarum Amarum."

"Mix 2 lbs. of fresh cake of bitter almonds (from which the oil has been expressed,) with enough water to form a thin pap. In twenty-four hours distill ¼ lb. by means of steam, conducted to the bottom of the still by a tube connected with a boiler. Filter the distilled water through wet paper."—*Paris Codex.*

M. Hænle proposes to mix half a drachm of essential oil of bitter almonds and ten drachms of diluted hydrocyanic acid (Pharm. Lond.) with twelve ounces of distilled water. The mixture to be well shaken and then filtered.

The dose of either form is given as from ten to forty drops.

Another substitute is the "Emulsio Amygdalæ cum Amygdalina," of Wöhler; and this is made by forming one ounce of emulsion with two drachms of sweet almonds, and dissolving in it seventeen grains of amygdaline. The formula for amygdaline is as follows:—Boil well pressed cake of bitter almonds twice in strong alcohol; strain through linen, and press the residue; remove any oil that may appear; heat the liquid again, and filter. In a few days, part of the amygdaline crystallizes. Concentrate the residuary liquor to a sixth part, and add æther, which will throw down the amygdaline. Press it between blotting paper; wash it with æther; re-dissolve in boiling alcohol, and set aside to crystallize.

According to the evidence given at the inquest, it appears that they (at Cronin's,) made their own "bitter almond water," and that it was in the proportion of six minims of essential oil of bitter almonds to a quart of water.

From *Gray's Supplement* we find that the formula for "Aqua Amygdal. Amar.," is bitter almond-cake, bruised, ¼ lb. draw off five gallons; and a second form is given under the name of "Aqua Amygdal. Amar. Concentrata." But upon this I hold we should not dwell, nor should any comparison be drawn, as it may savor of unfairness; for the "prescription" certainly does not contain the word "concentrata," although it is quite certain that the patient died by taking a like preparation.

The Aqua Amygdalarum Amarum., according to Cronin's nostrum, as known to himself was perfectly harmless; but how uncertain or indefinite to every one else what he really intended to be given, or the dose he meant to be taken.

As regards the other unaccepted article, the receipt of Brera runs thus:—

"Pulvis Strychniæ Compositus.

R. Strychniæ	gr. j.
Oxyd. Ferri Nigri	dr. ij.
Sacchari	dr. iij.

Misce et divide in partes sex."

The evidence given at the inquest farther informs us, that to make the "Compound Strychnine Powder," according to the defendant's mode, was, that he put two grains of strychnine to half an ounce of sugar. Now in this no mention is made of the black oxide of iron, which is found in Brera's formula; and moreover, the proportionate quantity of strychnine is much greater. This is adduced to shew the vagueness of what was ordered, although it must be admitted that the small quantity of two grains of the private form of the Pulvis Strychniæ Compositus, in a six ounce mixture, could not contribute to the sad event, if it had formed part of the compound.

A MEMBER.

General Retrospect.

ANATOMY AND PHYSIOLOGY.

ON THE NERVES OF THE TONGUE.

An important memoir on this subject, by MM. Biffi and Morganti, contains the following conclusions:—

1. The glosso-pharyngeal nerve, independent of its special sensibility, possesess an exquisite sense of touch, as was demonstrated by experiment on dogs and horses.

2. The pharyngeal branch of the glosso-pharyngeal is not constant in its manifestations, sometimes it possesses an exquisite sensibility, at others it is quite insensible.

3. The glosso-pharyngeal does not possess motor powers.

Müller maintains that the nerve exhibits motor functions after it has merged from the cranium. To verify this assertion, the authors have repeatedly performed the following experiment:—Having sawed the cranium of a living animal into lateral halves, so as to expose also the pharynx and tongue (!!), they removed the brain and cerebellum, and isolated the medulla oblongata and the fasciculus of nerves which emerge by the posterior foramen lacerum. The glosso-pharyngeal is then pinched, upon which it is found that no movement takes place in the pharynx or tongue; but on the other hand, that vivid contractions are induced by irritating the accessory nerve of Willis.

The movements which have been witnessed by Longet, Guizot, and Mayo, upon irritating the nerve, the author believes to be excito-motory, as the same may be excited by irritating the cerebral extremity of the nerve after its division.

4. The glosso-pharyngeal is the nerve of taste for the velum and pillars of the palate and the posterior two-thirds of the tongue.

5. The anastomotic branch of Jacobson is neither motor nor gustative, but possesses acute tactile sensibility.

6. The pharyngeal branches of the pneumo-gastric are not gustative, but are mixed motor and sensitive nerves.

7. The lingual branches of the fifth pair, besides other specific sensibility, possess the sense of touch, but to a less degree than the other branches of the fifth.

8. The lingual branches of the fifth pair have no motor function, but may be the incident nerves of a reflex movement.

9. The anterior third of the tongue receives its sense of taste solely from these nerves.

10. The corda tympani is sensitive but not motor; it exercises some influence over the intensity of the sense of taste.

11. The hypo-glossal nerve has no specific sensibility, but is the chief motor-nerve of the tongue.

Such are the results of the authors' experiments, many of which, our readers need not be told, are at variance with those of other physiologists, more particularly those connected with the corda tympani, a nerve which, in the opinion of Bernard, (*Gazette Méd.*, 1845,) is thought to possess motor powers as well as to be instrumental to taste. The authors at least appear to have exercised care in their observations, and took the very necessary precautions after exposing a nerve, to suffer the animal to recover from the immediate effects of the operation, previous to resorting to farther experiment.—*Gazette Méd.*, Mars 6, 1847.

PATHOLOGY.

BUFFY COAT OF THE BLOOD.

In a memoir on the signification of the buffy coat and on the production of the blood corpuscles, Remak concludes with the following practical remarks:—

1. In order to arrive at a certain appreciation of the diagnostic and prognostic value of the buffy coat, it is requisite that the blood, in all cases of venesection, should be collected in high and narrow vessels. It frequently happens that when broad vessels are used, and the coagulation proceeds irregularly, no buffy coat is formed; when, if collected in another manner, it would have undoubtedly appeared—a fact which though generally known, is very little attended to. Since attention has been paid in Schönlein's "Clinique" to the mode of collecting the blood, and its coagulation has been carefully watched, a buffy coat has been observed in every case.

2. The microscopic examination of the buffy coat in relation to the quantity of colourless blood-cells, may be made highly useful in determining its importance, as indicative of the stage of inflammation. The absence of many colourless blood-cells in the buffy coat, affords a much more certain indication of an unusually large amount of fibrin arising from inflammation, than does the presence of a great number, the latter condition being generally dependent upon the regeneration of blood after repeated venesections, and probably connected with an imperfect metamorphosis of the cellular elements of the blood in dyscrasic diseases, such as typhus, glanders, scurvy, and cancer. —*British and Foreign Medical Review*, April, 1847, p. 507.

ANALYSIS OF LYMPH.

The analysis of lymph by M. Laugier, given below, differs somewhat from those previously given. The specimen experimented upon contained—

Water	983.7
Fibrin	0.4
Albumen	6.2
Extractive matter	2.7
Fixed salts	7.0
Fats, &c.	traces
	1000.0

The chief difference between this and other analysis consists in the small amount of fibrin, which varies usually from 1.2 to 5.2.—*Ibidem.*

ON THE FIBRIN OF THE BLOOD.

In a long memoir, Zimmerman engages in numerous enquiries connected with the chemical composition of the blood, the principal results of which are embodied in the following propositions:—

1. The fibrin of venous blood is soluble in a solution of nitre. The solution always takes place irrespective of the quantity of the salt, or of the water, or of the degree of temperature.

2. We are not as yet sufficiently acquainted with the solubility of the fibrin of human arterial blood, but it is less soluble than that of venous blood. The fibrin of both the venous and the arterial blood of the ox is nearly insoluble; that of the dog is very soluble. In the horse the arterial fibrin is more soluble than the venous.

3. Heat favours, and cold retards the solution of coagulated fibrin.

4. Dissolved fibrin resembles albumen, as being coagulable by æther.

5. Fibrin is rendered insoluble by boiling water.

6. The fibrin of exudations is as soluble as that of venous blood.

7. The inflammatory crust of the blood is very sparingly soluble.

8. Putrefaction favours the solubility of fibrin.

9. Compression of fibrin renders it more insoluble.—*Archiv. für Physiologische Heilkunde.*

MICROSCOPICAL OBSERVATIONS ON ICTHYOSIS.

By M. Nicolucci.

The following observations were made upon a woman, aged 70, who had laboured under icthyosis of the leg for five years. The scales which detached themselves, seen with the naked eye, appeared to resemble shagreen; viewed on their adherent aspect, they appeared to be areolar; viewed in their perpendicular aspect, they appeared to consist of small columns, one extremity of which rested on the skin, the other forming the superficies of the eruption.

Under the microscope the same columns were noticed, but it was farther noticed that they were tubular, and were united by some intermediate substance. The investing membrane appeared destitute both of cells and fibres. In the interior of the tubes were seen cells of 1-60th to 1-100th of a line in diameter, with nuclei of 1-240th of a line; each nucleus contained a nucleolus. Of these cells, some were oblong, others many-sided; each contained from one to five nuclei.

The intertubular substance was composed of cellules of 1-100th to 1-150th of a line in diameter, with nuclei, but no nucleoli. This substance, as well as the tubes, became transparent under acetic acid.

These investigations throw some light on the pathology of icthyosis. Most authors state that in this disease the epidermis alone is implicated, but the preceding results appear to show that the new production of icthyosis has a greater affinity to certain horny growths. For this reason M. Nicolucci suggests that the disease should be called *Keratosis*, from *Keras*, a horn.—*Gazette Médicale*, Mars 6, 1847.

SURGERY.

SUBMUCOUS SECTION OF THE SPHINCTER ANI IN VARIOUS SURGICAL DISEASES.

[This simple operation has been successfully performed by Blandin, Guerin, Velpeau, and Demarquay, in spasmodic stricture of the sphincter ani, permanent contraction of the muscles, fissure of the anus, &c. The latter author has published a long paper upon the subject, a translation of which appears in Dr. Ranking's "Half Yearly Abstract," from which we quote the following extract.]

"*Description of the Operation.*—The rectum must be previously evacuated; the patient placed as for the operation of Boyer. An assistant raises the buttock of the side opposite to that in which the section is to be made; this is always done on one of the sides of the anus, in order to cut the sphincter in its middle; an ordinary tenotome, or a particular bistoury proposed by M. Blandin, may be employed. The first is inconvenient from not being long enough, nor sufficiently guarded, and it may cut or tear the mucous membrane, the perforation of which might be the cause of serious accidents.

"M. Blandin's instrument is a bistoury, with a strong handle, and a moveable plate on one of the faces of the blade; the plate is rounded at its extremities, a little longer than the blade, and when closed it covers it completely. There are marks on the handle which indicate the direction of the edge. The operation is performed with this instrument alone. When it is required only to puncture the skin, a small part of the blade is uncovered; when the bistoury is to pass between the muscle and the mucous membrane, the blade is hid by the moveable plate, and the instrument acts as a smooth and slightly flattened stilet. When it is required to cut, the plate is drawn into the handle, and the instrument is used as an ordinary bistoury.

"The operation is simple; it is necessary—1. To make a small opening in the skin. 2. To introduce the finger into the rectum at the same time that the skin of both sides of the anus is made tense. 3. To pass the tenotome or bistoury between the mucous membrane and the sphincter. 4. To divide the latter.

"The puncture of the skin is generally made two or three centimeters from the anus. The instrument should pass gently, in order to detach the parts as little as possible. This is the most delicate part of the operation, especially as the instrument passes the level of the sphincter. In one case, to avoid the difficulty, M. Velpeau cut from below upwards, but this practice is attended with inconveniences. At the moment when the division is made, a kind of snap may be heard, and immediately after the operation a space is distinctly felt between the divided parts of the muscle.

"After the operation the cutaneous incision is dressed with cerate, or cold-water compress, and in a few days the cure is complete. The patient should be kept in bed, and defæcation prevented for several days. Hæmorrhage or inflammation occasionally supervene, but have never been found to prevent a favourable result. Occasionally, as in one of the instances quoted, the operation is required on both sides."

TURPENTINE COLLYRIA.

M. Laugier has lately made use of this application in several cases at the Hôpital Beaujon. His experiments were made upon cases of conjunctivitis, both acute and chronic ptosis, dacryosistis or inflammation of the lachrymal sac, and also sclerotitis, all of which had been (we will not say correctly,) already treated with a collyrium of nitrate of silver, and consequently appeared to the author to be the most appropriate for judging of the comparative effects of the two remedies. The formula which he gives is as follows:—To twenty

grains of Venice turpentine, heated in an earthenware mortar, add, when sufficiently fluid, twenty drops of the essence of turpentine, and triturate: three or four drops of this to be dropped between the eyelids night and morning. Its action was most beneficial, and seemed preferable to that of the nitrate of silver, employed in the strength of fifteen centigrammes in thirty grammes of distilled water. M. Laugièr afterwards tried it with a number of externe patients attending the hospital, and affected with acute disease of the conjunctiva and cornea, who had not been submitted to any previous treatment, and their cures were sufficiently numerous and rapid to testify to its harmlessness and efficacy. The proposer of this remedy suggests the propriety of employing the turpentine in the form of an ointment, by mixing it with some fatty substance. He has used the pure oil of turpentine; it however, increased the pain exceeedingly; he therefore recommends its administration in the formula already given.—*Dublin Quarterly Journal*, 1847.

TREATMENT OF ENLARGED SUBCUTANEOUS BURSÆ.

When matter is formed in these bursæ, the only means is the evacuation of the fluid by a free opening; this is unattended with danger, and followed by a rapid and complete cure. When, however, the bursal affection is recent, the skin thin, and the fluid probably a mere increase of the natural secretion of the cavity, the employment of blisters, or the external application of the tincture of iodine, is the best means of lessening the swelling; but it will probably return. For a complete cure, or in those cases where the swelling does not yield to the application of blisters, or to the external application of iodine, more especially if the swelling be not large, the best plan of treatment is to introduce a fine thread through the swelling, and use it as a seton. On the second day this generally causes considerable pain and requires withdrawal. A small quantity of puriform fluid passes for a few days through the opening, after which the swelling gets gradually less, and contracting is completely cured. Very frequently the bursa suppurates so freely as to require a free opening, the hole for the thread having closed. Although this is an extra source of pain, yet the cure is more complete, and quite compensates for this accident. Removal of bursæ simply for their inconvenience is a serious matter.—*Ormerod's Clinical Observations*, p. 90.

HÆMORRHAGE FROM LEECH BITES.

In order to arrest the hæmorrhage from leech bites M. Morand advises the application of a mixture of six parts of olive oil, and two of yellow wax; this is to be spread in a thin layer over the bleeding orifices, previously wiped dry.—*Brit. and For. Rev.*, April 1847.

CHEMISTRY.

NEW TEST FOR PRUSSIC ACID.

By Professor Liebig.

When some sulphuret of ammonium and caustic ammonia are added to a concentrated aqueous solution of prussic acid, and the mixture heated with the addition of pure flowers of sulphur, the prussic acid is converted in a few minutes into sulphocyanide of ammonium. This metamorphosis depends on the circumstance, that the higher sulphurets of ammonium are instantly deprived by the cyanide of ammonium of the excess of sulphur they contain above the monosulphuret; for instance, if a mixture of prussic acid and ammonia be added to the pentasulphuret of ammonium, the solution of which is of a deep yellow colour, and the whole gently heated, the sulphuret of ammonium is soon decolorized; and when the clear colourless liquid is evaporated, and the admixture of sulphuret of ammonium expelled, a white saline mass is obtained, which dissolves entirely in alcohol. The solution yields, on cooling or evaporation, colourless crystals of pure sulphocyanide of ammonium. Only a small quantity of sulphuret of ammonium is requisite to convert, in the presence of an excess of sulphur, unlimited quantities of cyanide of ammonium into sulphocyanide; because the sulphuret of ammonium, when reduced to the state of monosulphuret, constantly re-acquires its power of dissolving sulphur and transferring it to the cyanide of ammonium. The following proportions will be found to be advantageous:—Two ounces of solution of caustic ammonia of 0.95 specific gravity, are saturated with sulphuretted hydrogen gas; the hydrosulphate of ammonia thus obtained is mixed with six ounces of the same solution of ammonia, and to this mixture two ounces of flowers of sulphur are added; and then the product resulting from the distillation of six ounces prussiate of potash, three ounces of the hydrate of sulphuric acid, and eighteen ounces water. This mixture is digested in the water-bath until the sulphur is seen to be no longer altered and the liquid has assumed a yellow colour; it is then heated to boiling, and kept at this temperature until the sulphuret of ammonium has been expelled and the liquid has again become colourless. The deposited, or excess of, sulphur, is now removed by filtration, and the liquid evaporated to crystallization. In this way from $3\frac{1}{3}$ to $3\frac{1}{2}$ ounces of dazzling white dry sulphocyanide of ammonium are obtained, which may be employed as a re-agent, and for the same purposes as the sulphocyanide of potassium. Of the two ounces of sulphur added, half an ounce is left undissolved.

The behaviour of the higher sulphurets of ammonium towards prussic acid furnishes an admirable test for this acid. A couple of drops of a prussic acid, which has been diluted with so much water that it no longer gives any certain re-action with salts of iron by the formation of prussian blue, when mixed with a drop of sulphuret of ammonium and heated upon a watch-glass until the mixture is become colourless, yields a liquid containing sulphocyanide of ammonium, which produces with persalts of iron, a very deep blood-red colour, and with persalts of copper, in the presence of sulphurous acid, a perceptible white precipitate of sulphocyanide of copper.—*Liebig's Annalen*, Jan., 1847. —*Chemical Gazette*, April 1, 1847.

MODE OF REMOVING THE STAINS OF NITRATE OF SILVER FROM LINEN.

Mr. Herapath states that these stains consist of finely divided metallic silver, in intimate union with the tissue of the cloth. They are immediately removed by

the following plan:—The spotted linen is to be strained over a basin of hot water, and a few drops of tincture of iodine are to be dropped on each spot, previously moistened with water. Upon them is then to be poured sufficient of a solution of the hyposulphite of soda to dissolve the iodide of silver thus produced, and the tissue is immediately to be washed in warm water. The tincture of the pharmacopœia, and a solution of one drachm of the hyposulphite of soda, in two ounces of water, are the preparations recommended.

Taking into consideration the immense destruction of linen which is caused by the use of lunar caustic injections, the above suggestion is extremely valuable. —*Pharmaceutical Journal*, April 1, 1847.

TOTAL ABSTINENCE AND MEDICAL TESTIMONY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

My attention has been called to this important subject, by the letter of your correspondent θ, in the last number of our greatly improved Journal; and for the instruction of your readers, and the worthy gentleman's inspection, I beg leave to annex the articles of declaration to which he refers, and which he characterizes as containing "assertions unproved, and consequently, rash and dangerous."

"We, the undersigned, are of opinion—

"I. That a very large portion of human misery, including poverty, disease, and crime, is induced by the use of alcoholic or fermented liquors, as beverages.

"II. That the most perfect health is compatible with total abstinence from all such intoxicating beverages, whether in the form of ardent spirits, or as wine, beer, ale, porter, cider, &c.

"III. That persons accustomed to such drinks, may, with perfect safety, discontinue them entirely, either at once, or gradually after a short time.

"IV. That total and universal abstinence from alcoholic liquors, and intoxicating beverages of all sorts, would greatly contribute to the health, the prosperity, the morality, and the happiness of the human race.

"JOHN BOSTOCK, M.D., F.R.S., F.L.S.

"RICHARD BRIGHT, M.D., F.R.S., Physician to the Queen.

"Sir B. C. BRODIE, Bart., F.R.S., Sergeant-Surgeon to her Majesty.

"Sir W. BURNET, K.C.H., M.D., F.R.S., Physician General to the Navy.

"W. F. CHAMBERS, M.D., F.R.S., Physician to the Queen and Queen Dowager.

"Sir JAMES CLARK, M.D., F.R.S., Physician in Ordinary to her Majesty."

Now it is but fair to ask your correspondent, which of the four very plain statements he finds so rash and dangerous? He talks of no consideration being given to the evidence on which "such propositions, regarded as scientific truths, may be supposed to rest;" again, that an easy good nature, *hardly* excusable, has caused the signature of many to be given, &c. Now, really Mr. Editor, these comments are not in very good taste, considering the high character, in science and morals, of the men who have appended their signatures; neither does it greatly indicate the philosophical acumen of this defender of drinking usages.

The quotation from Liebig* goes for nothing; indeed that illustrious chemist distinctly states that beer and spirits are *not* elements of nutrition, but merely elements of respiration. With regard to the opinion of Mitscherlich, that alcohol is formed in our system from the sugar of our ordinary food, I should like to know what the supposed quantity may be per diem? and even supposing the fact proved, which it never has been, the analogy is bad, and no more proves the benefit of these stimuli as daily drinks, than the physiological fact of free muriatic acid being formed in the stomach during digestion, would argue the importance of our drinking daily this corrosive poison.

But, lest θ should be supposed to be an advocate of intemperance, he winds up his arguments by a *qualified* condemnation of the evils connected with these habits, at the same time solemnly cautioning his medical friends to pause!! "ere they bring their characters as men of science into question, by assertions which are not borne out by well ascertained facts in physiology and chemistry."

Really there is something of the ludicrous in a nameless member of our Provincial Association, from his concealed retreat, uttering oracular cautions to such men as Bostock, Bright, Brodie, and others, and the absurdity of which, I think on mature reflection, he must acknowledge.

The subject altogether is most important, and did I not fear occupying too much space in your valuable columns, I could show θ from the most undeniable evidence, that the generally-received opinions about the *nutritive* qualities of stimulating beverages are *quite worthless*; and also, that in very many cases, the only chance of breaking through the mischievous habit of drinking, is by total abstinence.

I admit that temperance, in a well regulated mind, may be all that is necessary; but alas! for one man or woman who can stop at the right point, there are hundreds to whom the cup is truly Circean, and its draught a physical or moral poison.

Excuse the length of my yarn, for I have a great horror of long letters,

And believe me,

Yours respectfully,

EDWARD HUMPAGE.

Bristol, April 23, 1847.

THE PROVINCIAL MEDICAL DIRECTORY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

A very sensible letter appears in your journal of March 24th, signed "Candidus," in reference to the "Provincial Medical Directory," publishing the names and residences of persons as medical practitioners, leaving us to guess the grounds of qualification to any such title they may possess. I, for one, consider it the duty

of the proprietors of that Directory, not only *to omit* all names sent to them, devoid of title through the *modesty* of their applicants, but also to *ascertain* that those, to whose names titles are affixed, do really possess such. This of course would entail on the proprietors of the Directory, the trouble of examining the printed lists of the various licensing bodies; but it would at the same time enhance the value of the Directory, which is otherwise a record devoid of utility, and an encouragement to quackery and imposition. I think I could select a name or two, for which their owners (as men of letters,) can make no higher claim than appending to their patronymics now in that Directory, the letters M.S.O.F., that is to say, Member of the Society of Odd-Fellows. The Directory ought to be a true book of reference of qualification, or cease to be at all.

I am, Sir, yours, &c. &c.,

Honiton, Devon. M.S.O.F.

Medical Intelligence.

MEDICAL REGISTRATION BILL.

On Tuesday, April 20th, Mr. Wakley obtained leave to introduce a Bill "For the Registration of Qualifed Medical Practitioners, and for Amending the Law relating to the Practice of Medicine in Great Britain and Ireland." The Bill bas been printed, and is ordered to be read a second time, on Wednesday, May 5th.

"Probably this is the last Parliamentary effort that will be made in the present generation to obtain an Act for the Registration of Qualified Medical Practitioners, and for amending the present anomalous condition of medical law. If an immense majority of the medical practitioners of Great Britain and Ireland unite their exertions in support of the Bill, they will obtain a law which will confer both upon them and the public inestimable advantages. If the profession be indifferent, Parliament will be indifferent, and the Bill must be lost."—*Lancet*, April 24th.

THE JACKSONIAN PRIZE.

At the late meeting of the Council of the Royal College of Surgeons, the prizes founded by the late Samuel Jackson, Esq., were awarded to Mr. Thomas Callaway, jun., of London, for his Dissertation on Luxations and Fractures of the Clavicle, Scapula and Scapular End of the Humerus, and Treatment; and to Mr. Edward Hulme, of Exeter, for his Dissertation on Asphyxia, its various Causes, Forms, and Treatment.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, April 16th, 1847:—P. A. La Fargue; W. Yonge; F. Moore; S. Wilks; H. R. Rump; T. Webb; J. E. Ellerton; E. Adams; W. D, Michell; D. Hughes; C. Munday.

Admitted Members on Wednesday, April 21st:—H. B. Gibbon; A. Ferguson; J. V. Hughes; J. Harwood; J. S. Pearse. W. S. Shipton; W. M. Fairbrother; R. D. Harris; J. E. Gannon; W. H. Sproston; J. L. Cotter; G. Fry; J. T. Campion.

Admitted Members on Friday, April the 23rd:—G. F. Jones; T. J. T. Williams; W. D. Eddowes; J. W. Hubbard; J. L. Worship; T. Armstrong; A. R. H. Podmore; A S. Willcox; J. Ferguson; W. H. Baylis.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, April 15th, 1847:—Frederick Freeman Allen, Market Harborough; William Palmer, Rugeley; William George Harvey, Penzance; William Mott; William Ellis Hambly, Kingsend, near Plymouth; Abraham Jubb, junior, Halifax; William Price, Wrexham; Edward Haycock, London; William Alexander Bryden, Wadhurst.

Admitted Thursday, April 22nd:—Morgan Thomas, Vale of Neath, Glamorganshire; Henry Turner, Sherborne, Dorset; Hubert Shelley, Epsom; Charles Thompson, Salisbury; Peter Eade, Blofield, Norfolk; George Hother, Lewes; George Browne, Reading.

OBITUARY.

Died, March 8th, at Vienna, the Ritter von Raimann, Chief Physician to the Emperor of Austria.

April 2nd, in Gracechurch Street, London, Richard Casson, Esq., Surgeon, late of Hull, where, about twenty years ago, in conjunction with the late Dr. Alderson, he established the East Riding Lunatic Asylum.

13th, in Harley Street, William Maclure, Esq., Surgeon, aged 56.

19th, in Finsbury Circus, Thomas Bevan, M.D., aged 43.

24th, in Upper Stamford Street, aged 73, Forbes Macbean Chevers, Esq., a retired Surgeon of the R. N.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due, either to the Secretary of the district in which they reside, or to the Treasurer or Secretary of the Association.

ROBERT J. N. STREETEN, Secretary.

TO CORRESPONDENTS.

Communication have been received from Dr. Chambers; D. W. Davies; D. C. R. Hall; Mr. F. Buckell; Dr. Cullen.

The Harrogate Inquest-case is in type, but unavoidably postponed till next number.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

REPORT OF CASES OF STRANGULATED HERNIA, WITH OBSERVATIONS.

By Clement Hawkins, Esq.,
Surgeon to the Cheltenham Dispensary, and Female Orphan Asylum, Cheltenham.

With the concurrence of my friends, Messrs. Fowler, Eves, and Fricker, I am induced to publish the following cases and observations on strangulated hernia. Twelve of the fourteen cases occurred in the hospital practice of the two former gentlemen, and one each in the practice of Mr. Fricker and the late Mr. Whitmore. Although not a principal, through the kindness of the above named friends, I had the opportunity of witnessing and in many cases assisting in the treatment. The constitution of the Cheltenham General Hospital and Dispensary is such as to preclude the surgeons of the Dispensary department from performing capital operations. The rules of the Institution demand that all such cases shall be admitted into the house under the care of the surgeon of the week. These appointments are ably filled by Messrs. Fowler and Eves, who are the Surgeons to the Hospital. There are three Surgeons to the Dispensary who have nothing to do with the Hospital, the appointments in the Hospital are filled up from those of the Dispensary according to seniority.

Table of Cases.

No.	*Name of Operator.*	*Age.*	*Sex.*	*Species of Hernia.*	*Duration of Strangulation.*	*Results.*
1	Mr. Fowler	25	Male.	Inguinal	6 hours	Cured
2	Mr. Eves	25	ditto	ditto	10 hours	ditto
3	Ditto	19	ditto	ditto	8 hours	ditto
4	Mr. Fowler	25	ditto	Femoral	4 days	ditto
5	Ditto	63	Female	ditto	36 hours	ditto
6	Mr. Eves	46	Male.	ditto	24 hours	Died of hæmorrhage
7	Mr. Fowler	50	Female	ditto	4 days	Died
8	Mr. Eves	22	Male	Inguinal	6 hours	Cured
9	Mr. Fowler	45	ditto	Large scrotal	ditto	Died
10	Ditto	65	Female	Femoral	2 days	Cured
11	Ditto	33	Male	Inguinal (scrotal)	24 hours	ditto
12	Mr. Fricker, (private)	57	ditto	ditto ditto	4 days	ditto
13	Mr. Fowler	85	Female	Femoral	2 days	ditto
14	Mr. Whitmore	26	Male	Inguinal	3 days	ditto

Case I.

INGUINAL HERNIA, STRANGULATED; OPERATION; PERITONITIS: RECOVERY.

George Bleck, aged 25, a baker's servant, admitted into the Cheltenham Hospital, January 16th, 1839, with a strangulated scrotal hernia on the right side. He gave us the following history of his case:—Has had a hernia for more than three years, which has always been reducible, and he has worn a truss. Six months since he broke it, and he neglected to replace it. The rupture has often descended into the scrotum, but never to the extent it has done this day. About ten o'clock this morning, while he was lifting a heavy weight, the hernial protusion descended with great pain, and he could not return it. A druggist in the town saw him, and ordered him to go to the hospital. I saw him soon after his admission, at half-past twelve, a.m.; he was in excruciating agony, and was with difficulty retained in bed; he had a large tumour in the right groin, extending into the scrotum, very tense and painful, especially at the situation of the external abdominal ring, pain in the abdomen, constant vomiting, and constipation of the bowels. So tense was the tumour, that I was persuaded in my own mind that all efforts at reduction by the taxis would prove ineffectual. The warm bath was used, and the taxis employed by myself and Mr. Fowler to no purpose.

3. p.m. The operation was performed by Mr. Fowler. The sac being reached, it was carefully opened, but there was no fluid; a large quantity of small intestine with the mesentery was exposed; several glands in the latter were enlarged, and one was the size of a pigeon's egg; the intestine was exceedingly dark. The stricture was divided by Mr. B. Cooper's sheathed knife, and the contents of the sac were returned with considerable difficulty; the wound being united by sutures and plaster, he was sent to bed, apparently little relieved by the operation, and the following mixture ordered:—

Magnes. Sulph., dr. ss., ex Aq. Menth. Pip. oz. iss., quartis horis.

9, p.m. Is in great pain, lying on his back with his legs drawn up; countenance pale and anxious; pulse 90, small and hard; vomiting continues; thirsty; very restless; has passed a considerable quantity of fluid blood, unmixed with fæces, per anum; the bowels have not been opened since the 15th. We gave him a small quantity of gruel, with a few drops of brandy in it; he had also an enema of warm water, which returned without bringing away anything but blood. Ol. Ricini, oz. j., which made him sick.

Jan. 17th. Has had a tolerable night, but no stool; has passed more blood; pulse quick and full; tongue white; abdomen very painful; tendency to sickness. Hirudines 50 abdomini; haust aperiens.

4, p.m. Somewhat relieved. To have an enema of castor oil and turpentine, which produced no effect. Calomel, gr. iii; Opii, gr. ¾; tertiis horis.

10, p.m. Says he is easier, and disposed to sleep; pulse 100.

18th. Has had a quiet night; slept at intervals; has hiccough; bowels slightly moved; abdomen painful and tympanitic.

19th. Much better; a purgative draught produced several copious stools. A remission of all the symptoms followed.

20th. Has had a disturbed night, owing to the supervention of a diarrhœa, probably occasioned by the calomel and opium; has taken fifteen pills. Mist. Cretæ Comp. cum Liq. Opii Sedativo.

21st. Going on favourably; from this time he made a good recovery, the wound healed kindly, and he was discharged.

Case II.

INGUINAL HERNIA; STRANGULATION; OPERATION: RECOVERY.

Thomas Stoyle, aged 25, was admitted, Sept. 6th, 1839, under the care of Mr. Eves, with a strangulated hernia of the right side, which descended into the scrotum. He presented himself at the out-patients' room, and asked for a dose of medicine; the person who saw him very prudently examined him, thinking there was more anxiety of countenance than usual. A hernia was detected. He gave a most confused history of his case; he had never worn a truss. The symptoms present were,—tumour in the right groin, the size of a duck's egg, tense and painful; pain in the epigastric region; nausea; countenance pale and anxious; says he had a stool yesterday; pulse 100, very full; says the hernia only came down this morning. He was placed in the bath, and the taxis used, without effect. He was subsequently bled to 25 ounces from the arm, which induced syncope. Three hours after his admission Mr. Eves was sent for, who proposed an operation, which was not consented to. Ice was applied.

At 11 o'clock, p.m., eleven hours after his admission, as the symptoms were most distressing, vomiting almost constant, pain over the abdomen increased, pulse 120, he requested to have the operation performed, which was rendered very difficult by the cowardice of the patient. The sac was opened and contained no fluid, its contents were omentum and small intestine; the stricture which was situated high up the canal was very tight; the contents of the sac were returned with difficulty, owing to the resistance of the patient; the wound was united by sutures and plaster, with a compress and bandage. He expressed himself greatly relieved by the operation.

September 7th. Had a good night, and complains of little pain. As the bowels were not opened, he was ordered to take Ol. Ricini, oz. ss., quartis horis.

8th. He took two doses of castor oil without producing any effect.

Magnes. Sulph., dr. j., ex Aq. Menth. Sativ., oz., j., quartis horis.

9th. Bowels well acted on.

From this time he went on favourably, and was discharged October 1st.

Case III.

INGUINAL HERNIA, STRANGULATION; OPERATION: RECOVERY.

Henry Parker, aged 19, a mason, admitted February 22nd, 1840, under the care of Mr. Eves, at 9 o'clock,

p.m., with a strangulated scrotal hernia on the left side. He says he has had a rupture as long as he can remember, but has never worn a truss; it often descended into the scrotum, but he always has been able to return it in the recumbent position. After his day's work the rupture descended, and was harder than usual, and being unable to return it, he applied for admission into the hospital.

We found a tumour, the size of a large lemon, tense and painful; the testicle could not be felt; there was an evident constriction at the external ring; sickness; countenance very anxious; pulse full and hard; bowels opened this morning.

He was placed in the bath, and bled to sixteen ounces from the arm. The taxis produced no effect on it. Mr. Eves proposed the operation, which was consented to, and performed eight hours after the strangulation. The parts were very vascular, and the sac unusually thick; the sac contained a small quantity of fluid, small intestine, and a portion of mesentery; the stricture was at the inner ring, and was divided on the finger; considerable difficulty was experienced in reducing the intestine, owing to the quantity protruded. It was greatly congested. The wound was united as in former cases.

Feb. 23rd. Had a good night, and is free from pain; tongue white; pulse 94; bowels not opened. Mist. Magnes. Sulph.

24th. Had a good night, and is free from pain; pulse 90; tongue white; no evacuation from the bowels. To have an enema, which produced the desired effect.

25th. From this time he progressed favourably; the wound was a long time healing by granulation. A few weeks after this man was re-admitted, and the cicatrix had a sloughy unhealthy aspect, which would not heal. He was sent into the country, and did not again present himself. The hernia was radically cured.

Case IV.

FEMORAL HERNIA, STRANGULATION; OPERATION: RECOVERY.

Henry Trapp, aged 25, a coalheaver, admitted April 8th, 1840, under Mr. Fowler's care, with a tumour immediately below Poupart's ligament on the right side. He had been visited by two surgeons previously to his admission, who recommended him to go to the hospital, which he at first objected to, but afterwards consented.

2, p.m. I saw him, and found a tumour about the size of a partridge's egg in the right groin, circumscribed, moveable, and rather tender. The history was unusually obscure, he says he has had a swelling "off and on" for two years, which enlarged when he caught cold, but never disappeared altogether. Four days since it became larger, and he had great pain in his bowels, and sickness, which subsided after taking medicine. The bowels were opened on the 4th; vomiting has increased the last thirty-six hours. In about an hour after his admission he was visited by Mr. Fowler, who expressed some doubt in common with others as to the nature of the case. His countenance was free from anxiety; tenderness of the abdomen very slight; the impulse given on coughing was very trifling. It was agreed to watch the case, and he was ordered Ol. Ricini, oz. iss., cum Tinct. Opii, m. xv.

8, p.m. Mr. Fowler was sent for. The symptoms of strangulated hernia were well marked; pain in the abdomen severe; vomiting of green fluid; and hiccough. Under these circumstances it was deemed advisable to cut down on the tumour; an incision was made parallel with Poupart's ligament, and the dissection cautiously proceeded with, when the true nature of the case was discovered, (femoral hernia.) A small quantity of fluid escaped when the sac was opened; its contents were dark-coloured intestine. The stricture was divided on a director, and the intestine easily returned. The operation did not last more than five minutes.

9th. Had a tolerable night; bowels opened twice spontaneously; doing well.

10th to 24th. His recovery progressed without any interruption; he is only detained in the hospital till the cicatrix is sufficiently sound to bear the pressure of a truss.

Case V.

FEMORAL HERNIA; STRANGULATION; OPERATION: RECOVERY.

Ann Toby, aged 63, admitted April 24th, 1841, with a femoral hernia in a strangulated state on the right side. She is a healthy woman, and has had a large family. About sixteen years since, she perceived a tumour in her groin the size of a pigeon's egg, but took no notice of it, as it always diminished when she was in bed. Yesterday morning when using exertion, it descended, and became larger than usual; this was followed by griping pain and sickness; she took castor oil and salts, but vomited both. She applied to a medical man, who sent her immediately to the hospital.

On her admission, we found her in the following condition:—Pulse tranquil; countenance free from anxiety; bowels soft; little pain on pressure. The tumour was of a large size in the usual situation of a femoral hernia, soft; bowels confined; no sickness since the morning. Attempts were made to reduce the rupture in vain. As there seemed to be no urgent reason for operating immediately, a dose of calomel and opium and an aperient draught were ordered.

April 25th. She has passed a bad night, and has had feculent vomiting; after some persuasion, she consented to have the operation performed. The contents of the sac were intestine and omentum; the former was returned and the latter allowed to remain, as it was adherent. The operation was quickly performed, and the patient expressed herself much relieved; in six hours after it, she commenced taking the Magnes. Sulph. ex Aq. Menth. Piperitæ.

April 26. Had a good night, took two doses of the mixture, which operated freely.

June 7. She was discharged cured, with a truss.

Case VI.

FEMORAL HERNIA; STRANGULATION; OPERATION: DEATH.

Thomas Maisey, aged 46, a labourer, of spare habit, admitted May 3rd, 1840, under the care of Mr. Eves, with a femoral hernia on the right side. He says he has had a rupture six months, but has never worn a

truss; it descended, and became larger than ever the day previous to his admission; he had pain in the bowels, and was sick. The bowels were opened a few hours before the strangulation of the rupture. He was visited by a surgeon in the country this morning, who bled him largely, and endeavoured to reduce the hernia, but in vain. He sent him into the hospital at 10 p.m.

The usual symptoms of strangulated femoral hernia were present, but were not urgent, which perhaps in some degree may be accounted for by the combined effects of the treatment and the fatigue of the journey. The warm bath was used, and the taxis employed, without success.

Half past 11, p.m. It was decided that the operation should be performed. It proved to be a difficult one. On prosecuting the dissection a quantity of altered glandular structure was found between the fascia propria and the sac, resembling omentum. On clearing this away, and carefully dissecting, the sac was opened, and a small quantity of dark fluid escaped; the swelling sensibly diminished. A small portion of dark intestine was seen just protruding through the femoral ring; the stricture on it was so tight that neither the finger-nail nor director could be pushed beneath it, and the intestine was so extremely resistant from distention by air and fluid, that great caution was required to prevent its rupture. The hernia-knife was gently pushed onwards, its blunt point entered beneath, the stricture was divided, and the knuckle of intestine spontaneously retired. Previously to the performance of the operation he told us "*when he was cut he always bled freely.*" In three hours after the operation considerable hæmorrhage took place from the wound; the house-surgeon applied a compress and bandage to arrest it.

May 4th. I visited the patient with Mr. Eves this morning; a large quantity of blood had been lost; the bed was saturated, and it had run through it on to the floor beneath; the compress and bandage were removed; the wound filled with thin pale blood; no vessel could be discovered. We effectually arrested the hæmorrhage by including a considerable quantity of cellular substance in a ligature; the pulse was 70, and steady; has had no sickness nor pain since the operation.

In the evening the belly became tender; countenance flushed; tongue white. The following day intense peritonitis set in, accompanied by great exhaustion; calomel and opium were used with small quantities of brandy, and he died May 6th.

I was not present at the *post-mortem* examination. Mr. Eves informed me, that although there were appearances of peritonitis all over the cavity of the abdomen, it was not so severe as might have been expected. The bowels generally were dark-coloured and congested, but the portion strangulated was thickened, and the calibre diminished. The circulation was not re-established in it.

Case VII.

FEMORAL HERNIA; STRANGULATION; OPERATION: DEATH.

Mary Turner, aged 50, married, the mother of several children, was admitted a patient of the Dispensary January 2nd, 1841. I visited her immediately, and found her labouring under symptoms of strangulated hernia; the tumour was situated in the left groin. It appeared she first felt pain in her bowels, and vomiting, Dec. 31st, and sent for a person in the neighbourhood, who administered injections. When I saw her at half-past two, p.m., I ordered her into the hospital, as the symptoms were very urgent. The countenance was anxious, and of a leaden hue; vomiting feculent; pulse small and thready; the tumour was small, about the size of a pigeon's egg. I immediately after visiting her, called on Mr. Fowler, and requested his immediate attendance.

5, p.m., Mr. Fowler operated. The sac being opened, a portion of intestine of a very dark colour was seen; the stricture was divided, and by a little gentle manipulation the bowel was readily returned. A large quantity of greenish fluid escaped from the abdomen; the operation afforded no relief; the acute suffering remained unabated until death terminated her existence, twenty-four hours after the operation. The treatment consisted in the use of calomel, and opium, and leeching.

Post-mortem examination. The body was emaciated, and the abdomen swelled; on opening it the cavity presented marks of intense peritoneal inflammation, and contained about two pints of fluid, of a greenish brown colour; the peritoneum was highly injected; the intestines generally inflamed, and congested; the portion which was strangulated was situated at the junction of the great and small intestines, and the impression made by the stricture was visible; the coats of the bowels were softened, and easily separated.

Case VIII.

INGUINAL HERNIA; STRANGULATION; OPERATION: RECOVERY.

Isaac Neale, aged 22, a smith, admitted into the Cheltenham Hospital, under the care of Mr. Eves, August 15, 1842, with an inguinal hernia of the right side. He states that he has had a rupture as long as he can remember, but has never worn a truss. At seven o'clock, p.m., it came down, during the time he was at work, and was very hard and painful. When admitted he had acute symptoms; vomiting; anxiety and paleness of countenance; pain over the abdomen. The tumour was irregular in shape, tense and painful, and descended into the scrotum. He was bled to sixteen ounces, and put in the warm bath, and the taxis gently used, at one, p.m., both by Mr. Eves and Mr. Fowler, but without effect. Previously to the performance of the operation, by Mr. Eves, Mr. Fowler enquired of the patient if both testicles were in the scrotum, which question was not satisfactorily answered. Nothing particular occurred in the progress of the operation till the sac was reached, which was very thin, and contained no fluid; its contents were omentum and gut, the former lying anteriorily to the latter; the stricture, which was high up, being divided, after a little manipulation, the protruded parts were returned. The testicle was exposed, and had escaped through the ring, but had not descended farther than just through its mouth; it was rather smaller than

usual. The wound was dressed in the usual way, and the man expressed himself greatly relieved by the operation. His bowels had not been moved since the 14th. Liq. Opii. Sed., m. xv.

16th. Doing well; pulse 80. Mist. Magnes. Sulph., quartis horis.

17th. No stool; pulse 94, and sharp, [illegible] of pain in the wound and over the region of the heart, which is increased by inspiration; there has been a great discharge of serum from the abdomen.

18th. Bowels freely opened yesterday evening and again this morning; wound nearly healed. I made particular inquiry respecting the descent of the testicle; he told me "it never had been down like the other."

23rd. From this time he rapidly recovered, and was discharged cured.

Case IX.

LARGE SCROTAL HERNIA; STRANGULATION; OPERATION: DEATH.

John Hughes, aged 45, a milk carrier, was admitted January 9th, 1845, under Mr. Fowler's care. He has been accustomed to lift heavy weights; about a year since he observed a swelling in the right groin, which descended into his scrotum; it was about the size of an egg, and returned into the belly when he was lying down. He has never worn a truss. This evening, about seven o'clock, it suddenly descended, and was far larger than ever it has been before; he was immediately siezed with violent dragging pain about the navel, sickness, &c. He applied to a medical man, who gave him something to make him vomit. On his admission we found a tumour about one foot in length, and, I should think, measuring at least twenty inches in circumference, exceedingly tense and painful, especially at the external ring; the greatest pain was about the navel; his countenance was particularly anxious; pulse small and feeble; the surface of the body was cold. The house-surgeon, Mr. Hartley, agreed with me that any attempt at reduction by the taxis in this case would be replete with danger. He sent to Mr. Fowler immediately, who on his arrival, at one p.m., said, "Surely this cannot be all intestine and omentum," but on carefully examining it, was unable to detect any transparency. Mr. Fowler made gentle attempts to reduce the hernia, but was convinced with us that any great pressure from without would expose the man to imminent danger of bursting the bowel. The operation was immediately performed. Having exposed the sac, Mr. Fowler endeavoured to divide the stricture without opening it, but failed. On opening it, the contents were found to be a large quantity of small intestine and mesentery, but no fluid. The stricture, which was scarcely in reach of the finger, was divided, but the greatest difficulty was experienced in reducing the bowel, which in quantity would fill a hat; it was enormously distended by air; at length this difficulty was surmounted, and the wound united by four sutures. He expressed himself much relieved. Calomel, gr. iij; Opii., gr. iss.

Jan. 10th. Looks well; pulse 84; has been sick once.

11th. No evacuation from the bowels; looks depressed, resembling the appearance of a man who has had a severe accident; tongue loaded; pulse small, 90. Took a dose of castor oil, which made him vomit a large quantity of greenish fluid; an enema brought away a large quantity of fæces.

8 p.m. Belly sore; pulse 120; eyes depressed; there is a re-protrusion of the parts; he has all the symptoms coming on. He was largely bled from the peritonitis pentine fomentations were used; calomel and opium freely exhibited.

12th. All the symptoms became aggravated, and he died this afternoon.

Post-mortem examination twenty-four hours after death. The abdomen only was examined. The small intestines were glued together by recently-effused lymph; that portion which was protruded had not recovered from the pressure of the stricture; the mesentery was congested, and several ecchymoses were observed on it; there was much air, but little fluid, in the peritoneal sac and intestines.

Case X.

FEMORAL HERNIA; STRANGULATION; OPERATION: RECOVERY.

Ann Toby, aged 65, admitted October 18th, 1845, under Mr. Fowler's care, with a femoral hernia of the left side, in a state of strangulation. She has had a double femoral hernia for many years, and was operated on by Mr. Fowler, April, 1845. (*Vide* Case V.) She has worn a single truss since that period.

On the 16th while coughing violently the tumour on the left side descended, and was painful, the pain extending all over the abdomen. On her admission we found a tumour on the left side, of an irregular shape, evidently a femoral hernia. Countenance was anxious; pulse 88; sickness and obstinate constipation. No effect was produced by the use of the taxis.

Mr. Fowler operated about two hours after her admission. The sac contained no fluid nor intestine, only omentum, which was very red. Gimbernat's ligament was freely divided, and a portion of omentum returned, the greater part being allowed to remain in the sac. Liq. Opii, m. xxv.

October 19th. Going on well; bowels opened without any medicine.

November 16th. She has recovered without a bad symptom, and had a double truss applied.*

Case XI.

INGUINAL HERNIA, SYMPTOMS DUBIOUS; OPERATION; CONSTIPATION RELIEVED BY THE USE OF PURE MERCURY: RECOVERY.

Henry Strain, aged 33, a labourer, an in-patient of the hospital for amaurosis and cataract, complained to the house-surgeon, November 14th, 1845, of pain in the bowels, and a swelling in the left groin. He said he

* This poor woman died suddenly of disease of the heart in December, 1845. I examined the body. I found the hernial sac on the right side contained omentum, which plugged the femoral ring. The sac on the left side was indistinct, and contained nothing. The coverings of both were much thinner than I expected to find them.

had a rupture for the last ten years, and had worn a truss, which never kept it up properly. In the afternoon the hernia descended, and he was unable to replace it. He did not complain of it till the morning of the 14th. The tumour was situated in the left side, was of the size of a lemon, and descended partially into the scrotum; it was tense. He referred the pain to the external abdominal ring, and making a sudden twist;" there is a great distension of the abdomen, but no sickness; flatulence very considerable; his countenance does not betray the anxiety peculiar to cases of strangulated hernia; pulse quiet; bowels not opened for twenty-four hours. Cold applications and other remedies, calculated to disperse the flatulence, were used to no purpose.

In the afternoon, Mr. Fowler proposed an operation, as the belly was hourly becoming more painful. Although the symptoms present were more like colic than strangulated hernia, it was deemed proper to liberate the stricture. The sac contained colon and omentum; the stricture was easily divided, and the finger passed into the abdomen, but we were unable to return the intestine. The integuments were brought together over it. Liq. Opii Sed., m. xxx.

In the evening his symptoms were unrelieved, he complained of violent pain in the abdomen, which was sore. Pulse 90, small; countenance much distressed. Ol. Ricini, oz. j., ex Aq. Menth. Piperitæ.

Nov. 15th. Has passed a dreadful night; has been very sick; pain severe in the belly, which is enormously swollen. Had a turpentine enema, and full doses of calomel and opium were given. In the evening he was still worse. Pulse small, and sickness continued; hiccough constant.

16th. Another bad night. Pulse small and rapid; constant sickness; scrotum enormously swollen, and very red. Another enema was administered, which brought away fæces and wind. Cajeput-oil, and calomel, and opium, have been given freely.

17th. Symptoms aggravated; vomits stercoraceous matter; the enemata have produced no effect; he appeared to be in a hopeless state; hiccough constant.

18th. Much the same. Mr. Fowler ordered the calomel and opium to be omitted. Twelve leeches to the scrotum, which threatens to slough. In the evening he became much worse, the sickness and tympanitis increased up to the present hour; the bowels have not been opened satisfactorily. Two drachms of pure mercury were given him; as soon as he swallowed it, Mr. Hartley informed me he looked ghastly, and complained of a curious sensation in the seat of the hernia. A few hours after the exhibition of the mercury, he passed a copious stool in the bed, but the nurse told me there was no appearance of quicksilver in it. The inflammation of the scrotum has diminished; the sickness is checked.

20th. Sickness returned once to day; complains of great prostration; tympanitis rather increased; is unable to sleep.

23rd. Has continued much in the same state since the last note; he was sick to day after taking castor oil; tongue brown and dry; the wound is sloughy; face flushed. Poultice the wound.

27th. Since the last note he has improved; the tympanitic state of the abdomen has diminished; has become soft. Treatment pursued has been to sooth the parts, a light nutritious diet, laxatives, and sedatives.

December 1st. Has had a slight attack of erysipelas from excess of diet, suppuration is extending up the inguinal canal. On percussing the abdomen a dull rumbling noise is heard; the wound is gaping, and the coats of the intestine are visible; has still slight erythma of the face, which may perhaps be attributed to the mercury taken for the amaurosis, and since the operation.

17th. A small abscess in the scrotum was opened to-day; the hernial protrusion retires into the abdomen when he lies down, which may be consequent on the absorption of the omentum.

29th. Suppuration spreading upwards; Mr. Fowler slit up the integuments for four inches, and a large quantity of matter escaped.

Jan. 29th, 1846. From the time of the last note every thing went on well with him. The wound is now well and he was discharged cured, but the hernia could not be kept up by a truss.

Case XII.

LARGE INGUINAL HERNIA; STRANGULATION; OPERATION: RECOVERY.

W. H., aged 57, the subject of an irreducible scrotal hernia for some years past, sent to my friend Mr. Fricker, Dec. 12th, 1845. He complained of sickness pain in the abdomen, and obstinate constipation.

December 15th. Mr. Fricker kindly requested me to visit him. I found a corpulent man, leading a sedentary, abstemious, and regular life; his countenance was free from anxiety; great pain all over the abdomen; a large irregular tumour in the left groin, extending into the scrotum; he vomited stercoraceous matter, and had constant hiccough; pulse 110; has had no stool since Dec. 12th. Everything calculated to relieve him had been done by Mr. Fricker. An operation was proposed and declined. Opii, gr. iij., statim.

16th. The operation for strangulated hernia was performed by Mr. Fricker; the sac was opened and contained a large quantity of omentum and colon, the stricture being divided. A small portion of the omentum was removed, but as there was some bleeding we judged it prudent not to remove more; the colon was adherent to the sac inferiorly. The edges of the wound were approximated over the tumour, and two grains of opium were given.

17th. Appears depressed; no vomiting; pulse 120; pain in the lower part of the abdomen, but bears pressure well; countenance good; unable to take anything excepting a little cold water. As soon as any fluid enters the stomach it produces vomiting and hiccough. He took two grains of opium. Infus. Rosæ cum Magnes. Sulph. As soon as he took the first dose of medicine it produced violent vomiting of fæculent matter. Creosote, m. iij., which did not check the vomiting. In the evening we visited him, and

found the vomiting had not stopped. A small quantity of sherry and water remained on the stomach. Pulse 110; tongue clean; the least movement to the left side produces vomiting. We deemed it prudent not to vex the stomach with medicine, and left him for the night.

18th. Has passed a bad night; constant vomiting of fæcal matter; pulse 110; countenance remains good; tenderness of the abdomen increased. In the evening he said he felt "a movement of wind downwards." With Mr. Fricker's concurrence, I now ordered an enema of turpentine and oil, which produced a copious evacuation; his pulse fell to 90, and he felt exhausted and inclined for sleep. Calomel gr. v., cum Opii, gr. ij. In the evening we found him somewhat better, still he is harassed by hiccough; free from sickness. Mist. Effervescens cum Ammonia et Tinct. Opii.

12th. Unable to sleep on account of hiccough; pulse 84; tenderness of the abdomen considerable. Infus. Rosæ cum Magnes. Sulph., which operated freely. We prescribed some lemon ice in the day, which relieved the distressing hiccough.

20th. Has had several copious stools; is cheerful and doing well. The wound is healing by granulation.

From this time till the end of January, 1846, he went on favourably and is wearing a bag truss. The hernia is quite as large as it was before the operation; he complains of a dragging pain in the abdomen, and occasional irritation of the stomach and bowels.

Case XIII.

FEMORAL HERNIA; STRANGULATION; OPERATION: RECOVERY.

Jane Barnett, aged 85, admitted March 17th, 1847, under the care of Mr. Fowler, with a femoral hernia of the right side. Symptoms of strangulation have existed since the 15th; vomiting; constipation; slight tenderness of the abdomen; pulse 80. She is of a spare habit; there is a tumour in the right groin, about the size of a walnut; she has never worn a truss, and is the subject of a procidentia uteri, and very deaf.

8, p.m. Mr. Fowler operated; the whole proceeding did not occupy more than five minutes. The fascia propria and sac formed an agglutinated mass, much thickened, and there was a small quantity of fluid in it. The sac contained a knuckle of dark-coloured intestine; the stricture was divided on a grooved director, and the protruded part reduced. Calomel, gr. iij., Opii., gr. iss., were given.

March 18th. Has had no vomiting since the operation; no action of the bowels; urine drawn off by catheter; pulse 84. Ol. Ricini, oz. j.

19th. Has had several stools; countenance a little flushed; pulse 90. Ordered nourishing diet. Mist. Cretæ. Comp. cum Liq. Opii. Sed.

20th. The purging stopped. Meat diet.

26th. Quite well.

Case XIV.

CONGENITAL INGUINAL HERNIA; DESCENT OF THE TESTIS, INCOMPLETE; OPERATION: RECOVERY.

Mr. J., aged 26, sent for Mr. Whitmore, November 1st, 1832, late in the evening, complaining of pain in the bowels. A tumour, about the size of an egg, situated in the left groin, was discovered, tense and very painful on pressure. He had been sick, and felt slight pain in the bowels; no stool since October 29th.

After giving some general directions, Mr. Whitmore left him for the night, being in attendance on a dangerous labour. On visiting him the next morning, Mr. Whitmore found him vomiting, with an anxious countenance, and the usual symptoms of strangulated hernia. The warm bath, bleeding from the arm, and a moderate use of the taxis were tried, but the reduction of the hernia was not effected. Neither testis had descended into the scrotum. He gave the following history of the case:—

He has had a rupture as long as he can remember; and about fifteen months since he had a similar attack to the present one, while residing in the country. He sent for a surgeon, who failed in affording him any relief. Having dismissed this practitioner, he applied to a noted quack-doctor. The case being one of obstinate constipation, he administered a drastic purgative powder, which he called "golden dust;" and after each dose he made the patient walk about the room. The rupture was reduced.

At 12, p.m., Mr. Fowler saw the patient, with Mr. Whitmore; an operation was proposed and performed by Mr. Whitmore. The sac was opened, and a quantity of fluid escaped; the contents were omentum and bowel; the stricture being divided, they were returned. The testis was found lying in the sac, and at the mouth of the external ring; it was small, but otherwise healthy. The patient recovered without a bad symptom.

(*To be continued.*)

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(*Fourth Series of Experimental Researches.*)

By William Addison, M.D., F.R.S., Malvern.

(*Continued from page* 231.)

XIII. Regular, Irregular, Retrograde, and Ascending Metamorphoses in Animal Textures.

"If we examine the broken ends of a fractured bone from the first to the tenth day after the injury, we shall find the periosteum and medullary membrane torn, the neighbouring soft parts swollen, and an effusion of blood around and between the fragments. The periosteum is more vascular, *it has lost its fibrous character*, and a reddish fluid is effused into its substance. The medullary membrane undergoes similar changes,—the marrow assumes a kind of fleshy appearance, and a viscid gelatinous matter makes its appearance in the situation of the fracture.

"From the tenth to the twenty-fifth day the soft parts in the immediate situation of the fracture become more solid, and adhere more intimately to the matter between the fragments, which has now assumed the *fibrous form*, and the membrane filling the medullary

cavity is also connected into a *fibrous texture*. From the twenty-fifth to the fiftieth day this fibrous texture gradually becomes *fibro-cartilaginous*, and then *osseous*. In from three to six months the whole substance between the fragments is converted into *bone*, and the injured limb is restored to its natural state." *

The textures surrounding the extremities of a fractured bone are irritated textures; they have been violently torn and wounded, and their vascularity and nutritive actions are increased by reason of a law existing in all living textures, by which irritated parts have an increased amount of nutritive elements determined towards them for their succour, or to support them under the infliction. We see the demonstration of this law, not only in the transparent web of the frog's foot, and in all parts of the human structure, during inflammation in a fractured bone, and in the prick from a pin's point, but also in all kinds of vegetable structure. "Galls or tumid excrescences," says Dr. Lindley, in speaking of the diseases of vegetables, "are local affections, caused by the puncture of insects; they are produced by an excessive deposition of cellular tissue, and are of no consequence to the general health of the individual subject to them." In these cases of galls and excrescences, the little insect not only irritates the living texture, thereby causing an increased deposition of cellular texture, but it actually models the excess produced by the irritation to its own use and purposes. Now, the facts related shew that, in the repair of a fractured bone the morphological stages observed are,—first, a viscid protoplasma or lymph, derived from, and mixed with, colourless incoherent cells or corpuscles;—then a very vascular texture, excreting cells;—then a fibrous texture, less vascular, and not excreting cells;—then fibro-cartilaginous;—and lastly, osseous textures. This order being in all respects the same with that observed in the growth of the textures from their embryo state, is *therefore* regular. But it is of the utmost importance in regard to practical medicine that the phenomena of a regular metamorphosis should be regarded in respect of time, for although the several textures pass by insensible limits into each other, yet there are no difficulties in recognizing the distinctions between lymph, fungosities, fibrous texture, cartilage, and bone; or between pus, mucus, and abnormal fibrous textures, and tubercles. Let me therefore recapitulate the phenomena with reference to the times.

From the first to the tenth day the following series has been observed in the textures involved in the injury of a fractured bone:—(1.) The soft parts are swollen and there is an effusion of blood. (2.) The periosteum and the medullary membrane—*i. e.*, the irritated or injured textures,—become more vascular, a new matter is effused into their substance, and they lose their normal characteristics. (3.) The marrow assumes a fleshy appearance, from which a viscid glutinous matter, a protoplasma, is excreted. *From the tenth to the twenty-fifth day*:—(4.) The soft parts become more solid, cellular or corpuscular forms are excreted in less quantity, the number of blood-channels diminishes, and the matter between the fragments of bone assumes the fibrous form. (5.) The fleshy appearance filling the medullary cavity is converted into a fibrous texture. *From the twenty-fifth to the fiftieth day*:—(6.) This fibrous texture gradually becomes fibro-cartilaginous, and then osseous.

These are but rough approximations towards the establishment of times and periods, more accurate researches are required to establish correct stages for the normal morphology.

Irregular Metamorphosis.—In the disease termed rickets, the bones resemble very vascular cartilage, and the medullary canal is filled with a reddish gelatinous matter instead of marrow; the structure everywhere presenting a much more red and vascular appearance than healthy bone.†

I forbear to notice many local diseases and congenital defects which might appropriately perhaps be placed under this head,—nævi, warts, fatty tumours, &c., my attention being now confined to those irregularities and changes which connect scrofulous diseases with the law of the metamorphosis.

Retrograde Metamorphosis.—The facts, proving that phthisis or consumption is a retrograde metamorphosis of the parenchyma of the lung, have already been mentioned. In the disease termed mollities ossium, the smooth surface of the bone is raised by internal growths and red projections, visible through the periosteum. The cancellous cavities of the bone are filled with a gelatinous substance, composed of myriads of colourless cells, of different sizes, forming a soft incoherent cellular or corpuscular texture. In some cases the bones become so soft and flexible, that they may be bent in any direction; and they have the properties and appearance of a highly vascular texture, which secretes or excretes a gelatinous matter, "containing multitude of corpuscles, of the same size as the corpuscles of blood, each filled with a minutely granular matter."‡

In scrofulous joints we see, during the progress of the disease, almost every grade and variety of texture,—

* I am indebted for the above account to the industry of Mr. Gulliver, who has collected the facts bearing upon the subject from Dupuytren and Breschet, and stated them in his usual clear and satisfactory manner. Vide *Edinburgh Medical and Surgical Journal*, July, 1835. I have particularly examined with the microscope the nature of the "fleshy appearance" or fungosity, and find it a corpuscular excreting texture, full of blood-vessels, and abounding with colourless cells.

† "Cyclopædia of Practical Medicine." Art., Rickets.

‡ Solly—"Medico-Chirurgical Transactions," vol. xxvii; Cumin—"Cyclopædia of Practical Medicine." Art., Mollities Ossium; and Dalrymple—"Dublin Quarterly Journal of Medical Science," Aug., 1846.

pus, tuberculous matter, fungosities or granulations, lardaceous, fibrous, and cartilaginous textures. Fungosities or granulations are highly vascular textures, assuming a kind of fleshy appearance, excreting in abundance a viscid gelatinous matter, and colourless cells, (pus;) lardaceous tissue is an intermediate form between fungosities and fibrous texture; it is in fact a highly vascular corpuscular excreting texture, ascending to the fibrous non-excreting form, which is the natural order, and "its presence," as Bonnet states, "indicates a better state of constitution than the existence of fungosities alone does; but its metamorphosis into fibrous texture is indispensible to the recovery of the joint.*

Case.—"A pale-looking boy, sixteen years of age, came under treatment for dropsy of the belly and anasarca, and died gradually exhausted with hectic fever. He had no symptoms which could have revealed the existence of the disease found on examination after death. The cavities of the chest and belly contained much serous fluid. The peritoneum was everywhere thickened, and studded over with tubercles. The glands of the mesentery were enlarged and tuberculous. There was an immense abscess, containing four pints of curdy pus, situated on each side and in front of the spine, which was denuded of periosteum. The kidneys were enlarged and pale. There was a cicatrix on the inner aspect of the left shoulder, where an abscess had opened two years previously, which, after discharging matter for some time, healed. On opening the joint pus escaped; the articulating surface of the humerus was rough from being denuded of its usual smooth covering. A section exposed to view a perfect specimen of yellow tubercle, in the cancellated structure of the head and neck of the bone. The cancellated texture was deeply congested with blood, intensely red, and slightly softer, than in its healthy condition; in the midst of the red cancelli were seen the straw-coloured tubercles; similar tubercles were also found in the diseased lumbar vertebræ."†

In remarking on the above case, Dr. Watts states "that the formation of tubercle in the bones had been doubted by many, and it is only a few years ago that the question was satisfactorily determined in the affirmative. Respecting the manner in which tubercles form in the osseous structure, the cancellated structure becomes congested with blood, its nutrition is disturbed, it apparently has some tendency to soften, and a badly vitalized lymph is exuded in spots, and forms into tubercle, all of which may happen without the excess of heat or manifestation of pain usually attending inflammation."‡

We have seen in respect to a regular metamorphosis in the union of a fractured bone, and in the healing of wounds, that a viscid gelatinous matter, lymph, or protoplasma is an early morphological form, and also that a similar matter is almost universally found shading off into pus or tuberculous matter in scrofulous diseases. Louis, whose authority is paramount in all questions relating to the pathology of phthisis, says that he has detected this matter in both its principal forms,—granulations, and larger shapeless masses, in all the fibrous textures, in the pleura, on the free surface of the peritoneum, in the substance of the pia mater, and in the great omentum; and he adds that in all these situations he has found it susceptible of transformation into opaque tubercle, and in this opinion he coincides with the conclusion previously formed by Laennec. The observations of Louis, and the conclusions of Laennec upon this point, are quite in accordance with the facts and morphological doctrines deduced from my microscopical investigations, which have shewn that the lymph or protoplasma of the blood consists of colourless cells, molecules, granules, and nuclei, imbedded in viscid fibrillating material; that the lymph is suscepticle of conversion into pus by the addition to it of an unusual multitude of cells derived from the blood current; into fibrous texture, upon the fibrillation of the coagulable element; and into tubercle, by the rupture of the cells and degeneration of elements, when the morphological tendencies of the textures on which the lymph appears, are retrograde.

An increased redness or vascularity of a texture, with an increased nutritive activity and new products, has been considered characteristic of inflammation; but it is manifest, that an increased redness, with an increased nutritive activity and new products, followed by the union of a fractured bone by bone, has a very different result from the nutritive activity which fails, (in rickets,) to accomplish the required conversion into bone, and from that also which (in mollities osseum,) accomplishes the retrograde conversion of an osseous texture into a corpuscular one, which changes the textures of a joint (scrofulous joints,) into fungosities, tuberculous matter, and pus, and converts (in phthisis,) the coherent cellular parenchyma of the lung into similar degraded forms.

In the first example, the fractured bone, the injury gives rise to an increased vascularity and nutritive action, and the result is, that in a certain time "the injured limb is restored to its natural state." The limb being restored to its natural state, the metamorphoses is natural, and being natural, it is also conformable or regular. But an increased vascularity, with an increased nutritive activity, and conformable products, fulfils the definition before given of simple, healthy, or *conservative* inflammation; and it follows, therefore, that simple inflammation attends the reparation of a fractured bone. If the metamorphosis happen to be arrested at any stage short of perfect ossification, the limb will not be restored to its natural state; in that case the metamorphosis would be unconformable or

* The quotation is taken from the *British and Foreign Medical Review* Art. Bonnet—*Traité des Maladies des Articulations*, January, 1846.

† Dr. Watts—"Manchester Pathological Society."—*Medical Gazette*, Jan. 1, 1847.

‡ *Loc. cit.*

irregular, and the inflammation (the redness and vascularity,) *therefore* unhealthy.

In the second example, (rickets,) the normal metamorphosis is arrested, and the cartilaginous texture, notwithstanding its redness and vascularity, will not proceed to bone. The metamorphosis is therefore irregular; and if we call the redness and vascularity, inflammation, the inflammation is unhealthy.

In the third examples, (genuine scrofulous diseases,) mollities ossium, scrofulous joints, and consumption, the natural textures, from an *inherent disposition*, or an *irritation* coming from without, or from both these causes acting conjointly, are unable to preserve their type, and with an increasing vascularity, fall rapidly back into lower and earlier forms.

A retrograde metamorphosis, it will be observed, does not embrace any of the changes resulting from a loss of vitality, it simply expresses a fact of living structure,—the replacement of a later or higher texture by one of an earlier or more primary type, and the phenomenon is one of great energy and activity; new textures, new vessels, and new products, are as rapidly formed as when the structure was evolving from its embryo state.

In any comparison of the phenomena of a retrograde metamorphosis in plants, with scrofulous diseases in animals, wide differences and distinctions must of course be expected. Plants have no nerves nor muscles, nor have they a rapidly circulating corpuscular fluid or blood; their organs are more uniformly cellular in texture than those of animals, and thus in them it happens, that an entire organ may be converted into the form and shape of another; an event not observable in the more multiplied textures of the organs of animal bodies. Such a transformation, however, necessarily involves a change of texture, and it is with *the textures* rather than with *the organs*, that the morphological analogies between plants and animals must be traced. The retrograde metamorphosis in plants is to a green leafy parenchymatous texture, which having the properties of a solid, must therefore have a form and shape, and it is this which constitutes the abnormal leaf or leafy texture. In animals, the retrograde morphology is to the cellular elements and protoplasma of the blood, (the primary nutritive condition of the solid textures,) which having more the properties of a fluid than a solid, are therefore without definite shape or fashion. Hence the term ulceration is applied to scrofulous diseases in animal textures, in which the solid texture gradually softens, and being replaced only by a fluid or semi-fluid protoplasma, and incoherent cells, large excavations and hollow places, termed abscesses, are left filled with what is technically termed pus, or mucus; and the morphology is more rapid and energetic in animals, because a current of protoplasma and incoherent cells, is at all times ceaselessly flowing through all parts of their structure.

The general conclusion derived from these investigations is,—first, that a morphological law governs the transformations of the elements of the human structure, analogous to that established in respect of plants, in which the normal order is, soft corpuscular textures, coherent cellular, elastic fibrous, firm cartilaginous, and hard bone. The intermediate or transitional forms being fibro-corpuscular, fibro-cellular, and fibro-cartilaginous. Secondly, that whatever may be the type, or nature, or function of an organ, there is, as a consequence of the order or law of its evolution and nutrition, a disposition in the textures composing it—exhibited upon appropriate conditions applied—to revert or go back, especially during the period of their growth, to the primary incoherent corpuscular condition out of which they were originally metamorphosed. Thirdly, that scrofulous diseases are special examples of this disposition, proofs of an irregular and retrograde morphology. But as the conclusions here enunciated will hereafter be converted into principles for the prevention, treatment, and cure of scrofulous diseases, inflammation, and consumption; so therefore it is desirable, to support them by as many points of similarity between the growth of animal and vegetable textures, as occur to me at the moment.

In the first place, then, it has been stated, that in plants an inherent disposition to a retrograde metamorphosis is transmitted from the parent plant to the seed, and that unfavourable external conditions will produce the same result in otherwise healthy individuals, for in the human subject parents impart or transmit to their offspring an inherent disposition to scrofulous diseases, and unfavourable external conditions will bring about the same result.

"It may truly be asserted," says Dr. Cumin, "That no original temperament or frame of body confers immunity from scrofulous diseases, for it is observed to originate in the healthy offspring of healthy parents under circumstances the principal of which are habitual exposure to cold and damp, with insufficient food, privation of pure air, and want of healthful exercise. Instances are recorded where persons in good health have been affected with scrofulous diseases after being confined in dungeons or prisons, and there scantily fed. The influence of such causes in producing scrofulous diseases in the inferior animals, has been made the subject of experiment by Dr. Jenner, Dr. Baron, and others, and the results have satisfactorily proved, both the great extent of that influence, and the power we possess of removing the factitious disease by replacing the animals in healthy situations, and supplying them with wholesome food."

Scrofulous diseases in animals, therefore, have this additional analogy or similarity with the retrograde metamorphosis of plants, viz., that the phenomena arise in both from precisely the same causes,—an inherent disposition transmitted from parent to offspring, and

unsuitable external conditions; moreover, experience proves that no person can be considered as exempted from scrofulous diseases, and this result ought to follow if my conclusion be true,—for if these diseases be retrograde morphological states, arising from a law of nature pervading all living structures, there can be no exceptions in favour of individuals.

(*To be continued.*)

OPERATIONS PERFORMED UNDER THE INFLUENCE OF ÆTHER.

By W. C. Worthington, Esq., F.R.C.S., Senior Surgeon to the Lowestoft Infirmary.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

I was much struck with the value and importance of your remarks on the subject of æther-inhalation, contained in the Journal of March 10th, and am quite of your opinion, that practitioners residing in the country are imperatively called upon to co-operate with those of the metropolis, in helping to elucidate the use of the letheon, by a faithful record of cases. It must be acknowledged that great circumspection is required in the employment of any new agents, when it happens that the functions of so important an organ as the brain are manifestly influenced by its operation. In a former number of the Journal I reported the result of eight cases of surgical operation, in which the inhalation of æther had been employed. Since that time some further cases have fallen under my notice, which I beg leave to transmit for insertion.

Case I.

Thomas Rose, aged 42, a labourer at the Lowestoft Harbour Works, was received into the Infirmary March 5th, with his right hand severely crushed by the heavy bell of a pile-driving machine falling upon it. After the accident he was incautiously allowed to walk from the works to the Infirmary, a distance of three quarters of a mile. The fatigue arising out of this circumstance, added to the shock the nervous system had so recently sustained, caused a considerable degree of collapse to follow. Amputation was considered necessary, but the operation was deferred two or three hours, until some degree of re-action took place. Previously to commencing it, an attempt was made to letheonize the patient. After a few inhalations, his respiration became extremely hurried. At the end of two or three minutes, to the amazement of myself and those present, he started from his seat in a state of furious delirium, vociferating the most awful curses, at the same time stamping vehemently with his feet, and throwing his arms about in a most wild and frantic manner, requiring four or five persons to restrain him. This paroxysm lasted nearly four minutes, when he fell back in his chair, apparently somewhat exhausted. Upon returning consciousness, which soon took place, he remarked it was "*rum stuff he had been taking, but now was all right again.*" The operation was then performed, which he bore with calmness and fortitude. It was afterwards ascertained the patient was of an exceedingly irritable habit, and addicted to intemperance; and when under the influence of intoxicating drink, he became so exceedingly noisy and quarelsome, that it was with difficulty he could be prevented doing mischief. Here evidently was a case where the inhalation of æther was inadmissable, and it shows the importance of inquiring into the habit and temperament of individuals, previous to undergoing the narcotizing process.

Case II.

March 15th. Sarah Sullins, aged 43, a patient of the Infirmary, was narcotized previous to submitting to excision of the left breast for carcinoma. She went through the operation without any expression of pain, and when asked if she experienced any during its performance, she answered in the negative, but confessed she was not altogether unconscious of what was going on. After removing her to bed, she remained several hours in a perfectly tranquil state, and free from pain, her condition very much resembling that produced by a mild opiate. For some days she progressed favourably, when erysipelas attacked the wound, and thereby retarded recovery.

Case III.

April 7th. Mary Read, aged 22, an Infirmary patient, was narcotized previously to being operated upon for ganglion, situated on the anterior part of the wrist. A sharp-pointed straight bistoury was passed through the swelling, and a probe armed with cotton rapidly followed. On recovering from the effect of the æther she expressed herself as not being altogether unconscious that the operation had been performed, but suffered no pain. No unpleasant symptoms followed.

Case IV.

The same morning at the Infirmary, I removed the middle finger, at the metacarpal bone, of a man, aged 22. He was of an exceedingly calm temperament, and sober habits. No difficulty was experienced in narcotizing him. The stupor lasted nearly five minutes. When restored, his first impression was, he had been travelling on the railroad to Norwich, and had passed some days very agreeably with his friends. He manifested great surprise on being informed he had undergone the operation, and some minutes elapsed before he could be persuaded of the fact. No unfavourable symptoms followed.

At the Infirmary, on the same morning the two preceding operations took place, an aged female was couched in both eyes, and also another patient submitted to the extirpation of a malignant tumour from the inner canthus of the eye. In neither of these cases, however, did I deem it advisable to employ æther. The age of the former patient was considered a sufficient reason for not using it. The latter had for some months before been treated at the Dispensary of a neighbouring town for paralysis, from which she had not entirely recovered, and, notwithstanding she earnestly intreated to be permitted to inhale, the request was not complied with, upon the supposition that there might still exist a

condition of brain unfavourable to be acted upon by the narcotizing process. The patient was of an irritable habit, and exhibited great impatience under the operation. The tumour being deeply imbedded in the angle of the eye, and closely adherent to the conjunctival membrane, required some caution in its removal.

There were present at several of these operations, Dr. Wake, of Southwold; Mr. Garness, of Bungay; Mr. Hanner, of Wrenthaw; Mr. Jeffrey, of Lowestoft; also Messrs. Breame, and Prentice, assistant surgeons to the Institution, whose experience and tact in the management of the æther apparatus rendered their services particularly valuable to me.

W. C. WORTHINGTON.

April 16, 1847.

SOURCE OF THE CATAMENIAL DISCHARGE.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

The physiology or the source of the catamenial discharge, so peculiar to the human female, and the functions of the interior of the uterus positively ascertained, are subjects comparatively of very recent discovery, and as the opportnities are so rare of our having proof or of our obtaining any decisive means of determining the matter or establishing the fact, that the uterus is the source of this healthy and proper sexual secretion, I think the following evidence may be interesting to the readers of the *Provincial Medical and Surgical Journal*. Should you be of that opinion perhaps you will find room for it in an early number:—

On Saturday, the 27th ult, I was applied to by a medical friend to assist him at a *post-mortem* examination, under an order from the city coroner, of a woman who had hung herself, the jury not being able to agree in their verdict. It is not often that a medical man is called on to make a *post-mortem* examination for the purpose of assisting the jury in coming to a correct verdict after death from hanging, the cause of death being so palpably visible; and how that twelve wiseacres could suppose that we should, by an examination after death, be able to discover the motive that could have induced this poor creature to commit such a rash act I cannot conceive. But their ignorance was bliss *to us*, as it gave us an opportunity of making a very interesting examination.

The external appearance, and the gorged state of the blood-vessels of the brain, clearly proved that death had been caused by strangulation, and it also proved Dr. G. Burrows' theory on this subject to be correct. In removing the abdominal viscera we were struck with the size and vascular appearance of the uterus. As we understood she had been confined three months before, and the child soon after died, we thought the uterus might be impregnated, but on laying it open it presented to our view a most beautiful velvet-like appearance; the whole internal surface was covered with a dark, sanguineous mucus, which seemed to be exudating from it and could be easily scraped off. This unusual appearance we at once suspected to be the catamenial secretion, or the commencement of the process of menstruation. There was no appearance of any discharge in the vagina, and in order to satisfy ourselves on the point as to whether she had been regular since the birth of the last child, we made inquiry, and learnt from a female friend who lived in the house with her, that she had menstruated *once* since her confinement, and she thought that she was expecting it again in a day or two. There is then indisputable evidence, and the strongest corroborative proof of the fact, that the source of the menstrual discharge, once so much disputed, is the inner membrane lining the uterus, and I think the strongest case recorded. As it is well known, and many remarkable cases are recorded, that hanging has a very curious effect on the organs of generation of the male,—Query, Did the apparently enlarged uterus, and the vascularity of the external part of this organ, arise from the process going on within, or from the mode of death? Perhaps some of your learned readers may be able to inform me.

I am, Sir,

Your obedient servant,

GEORGE KING.

Bath, April 13, 1847.

Hospital Reports.

HÔPITAL DE LA PITIÉ, PARIS.

A CASE OF SCURVY, WITH PURPURA HÆMORRHAGICA.

Communicated by SEPTIMUS LOWE, Esq., M.R.C S.E.,

History of the case: present attack; symptoms on admission; continuation of the case; treatment.—Remarks; actual condition of the system.—Names applied by Professor Piorry, to express each organic change; alterations of the blood.—Andral's views.—Difference between scurvy and chlorosis; causes of the symptoms; differing from a case of true sea-scurvy. Probable causes; indications for treatment; prognosis.

L. B., a man aged 62, was admitted into the Hôpital de la Pitié under Professor Piorry, March 31st, 1847. He is of the ordinary stature; of strong conformation; pale, dusky, sallow complexion; and nervo-bilious temperament. He is a stocking-frame worker. Until within the last six years he was in very comfortable circumstances, had sufficient employment, lived well, was well clothed, and always very regular in his habits. During the last six years he has only been able to obtain a day's employment occasionally; he has consequently lived upon worse food, and been worse clad than formerly; he has also suffered considerable anxiety of mind. He is a native of Paris. For the last three months he has led a very irregular life; he has not been able to obtain a single day's employment; he has wandered about from place to place, generally sleeping in a close, damp, dirty apartment, together with several other persons; and has lived entirely upon brown bread (and that in insufficient quantity,) and water. He was formerly very robust,

and enjoyed excellent health, but for the last few years he has become much thinner and weaker. About thirty years since he passed several tape worms, and was in the hospital for about three weeks in consequence. Since then he has occasionally passed one; and the last he remembers to have seen was about two years ago. They did not occasion him much inconvenience, and he only felt a slight degree of uneasiness in the abdomen. During the excessive heat of last summer his feet became considerably swollen and œdematous, so that he could scarcely walk. After resting a few days the swelling disappeared, and he continued well, until within the last three months. Since last January he has been gradually getting thinner and weaker. He has had occasional diarrhœa, lasting three or four days, and alternating with constipation of the same duration. About six weeks ago he perceived his feet become again swollen, and soon afterwards a discolouration of the skin on the inner side of the left ankle and leg, as high as the knee; the skin in the hams became hard, and the calf of the left leg painful on pressure; he had a disagreeable taste in the mouth, the gums became swollen and puffy, with occasional oozing of blood from their surface. About a fortnight since he had frequent attacks of dizziness; he found he was not able to see at all in the evening, and was so feeble that he could not walk. From this time he has been confined to bed, and has been gradually getting worse and worse. He was not put under any treatment previous to his admission.

At present the surface is colder than natural; the skin is dry, and in several parts rough and scaly, especially on the inner parts of the legs and thighs, the sides of the trunk, and the back. In the hams the skin is excessively hard and thickened. The feet are swollen and œdematous, as well as the left leg and thigh. There are large patches of ecchymosis around the ankles, upon the legs, (especially the left one,) and on the sides of the trunk, from the axilla to the cristi ilii; there are also petechiæ on the thighs and upper extremities. On the left leg the skin is in parts of a deep yellow colour. Along the course of the internal saphena vein of the left leg there is considerable tenderness on pressure, and the discolouration is here more marked. The face is of a pale, dirty, yellowish colour; the lips are pale; the scleroticæ are yellow. The respiration is natural; the lungs are healthy in front, but behind there is slight emphysema on both sides; there is slight cough; the sputa are scanty and frothy. The heart is somewhat enlarged; the bruits are normal; there is no *bruit de diable* in the neck; the pulse is small, weak, frequent, and regular, 96 in the minute. The gums are swollen, with a dirty purple appearance; there is no oozing from their surface. The tongue is moist, furred, and very pale, and is marked along its borders by the pressure of the teeth; there is a disagreeable taste in the mouth, and the breath is exceedingly offensive; the appetite is tolerably good; there is no thirst, no nausea or vomiting, but slight uneasiness in the epigastric region after taking food. There is solid matter in the large intestines; the bowels are regular; the stools are solid and fœtid. The liver is smaller than natural. The spleen is normal. The urine is passed freely; is of the usual quantity, pale in colour, free from albumen, of alkaline re-action, and contains a flocculent cloud. The kidneys percussed from behind, are found to be of their usual size. Ordered a simple enema. To have full diet, consisting of fresh meat and fresh vegetables; to take three tablespoonfuls, of lemon juice three times a day; the legs and sides to be rubbed with sweet almond oil.

April 2nd. The patient complains that he cannot sleep well at night; there is tenderness on pressure on the calf of the left leg; the roughness of the skin on the legs is somewhat diminished; the bowels are regular; pulse still weak, but less frequent. Ordered to have a warm bath; the legs and feet to be elevated.

5th. The left leg is less swollen, and not so tender on pressure; the urine is rather higher coloured and still alkaline; the tongue is rather cleaner. Ordered to have a bandage applied from the left foot to the hip; continue the lemon juice, &c.

7th. The yellowness of the scleroticæ has disappeared; the gums are still spongy, but more healthy in appearance; the patient can see rather better in the evening, but he cannot clearly distinguish objects; the pulse is rather firmer; the urine is neutral; the bowels are regular. Continue.

10th. The tongue is cleaner, and not so œdematous; there is still a disagreeable taste in the mouth; the breath is less offensive; the swelling and œdema of the legs are somewhat diminished. Continue.

15th. The discolouration and roughness of the skin on the sides of the trunk have quite disappeared; the tenderness along the course of the saphena vein is much less marked; the aspect of the face is greatly improved; the urine is slightly acid. Ordered to continue the lemon juice, and to take a drachm of subcarbonate of iron three times a day.

From this time he continued to improve daily, both in strength and appearance. On the 21st the report is,—the face and general appearance are greatly improved; the gums are quite natural; the tongue is clean, but still rather pale; the heart, which measured five inches from base to apex, and three inches and a half from above downwards, now measures three inches in the latter direction, and four and a quarter in the former; the swelling of the feet and legs has entirely disappeared; the only discolouration of the skin now observed, is a slight yellowness on the left leg; the bowels are regular; the urine natural. The patient is convalescent.

24th. The improvement still more marked; the patient may leave the hospital in the course of a day or two.

Professor Piorry, in his clinical remarks, observed that this was a case still called by most authors scurvy, with purpura hæmorrhagica; these terms, like a great many others employed in medicine, were as unmeaning as absurd,—terms which presented to us none of the seizeable circumstances of the disease, nor indicated in the least degree the actual condition of the organs; but, if we studied the case carefully, symptomatically,

and scientifically, we should readily arrive at a just appreciation of the exact nature of the disease, be enabled to apply a sound and rational treatment, and be led to adopt expressions in accordance with the character and situation of each lesion. What did we find to be the condition of the system in the case before us? In the first place there was evidently hypoplastæmia or diminution of fibrin in the blood; 2nd, hydrhæmia or a watery condition of the blood; 3rd, hyphæmia or diminution of the blood-globules, commonly called anæmia; 4th, cardiasia or dilatation of the heart; 5th, phlebemphraxia or obstruction in the venous circulation; 6th, dermorrhagia or effusion of blood under the skin; 7th, hydrethmia or effusion of serum into the cellular tissue, &c. By applying these terms we expressed clearly and succinctly the whole chain of alterations in as few words as possible, and were enabled to seize at once each particular fact of interest in the case.

Besides these observations of Professor Piorry's, this case presents some points of considerable interest, and several of the important changes observed in it appear to be worthy of a more detailed account.

Dr. Elliotson, in speaking of scurvy, says "that it seems to be the universal opinion that it owes its origin to a morbid change in the fluids, and especially in the blood. Notwithstanding this general belief, there has been no attempt, up to the present time, at any chemical examination of scorbutic blood." But the late researches of Professor Andral appear to have thrown considerable light upon this subject. He observes in his "Hæmatologie Pathologique," that this disease (scurvy,) resembles chlorosis in certain respects, and both have many symptoms in common. In both we have the same feebleness, the same vertigo, the same aberrations of sensibility, the same dyspepsia, &c.; but what immediately distinguishes scurvy from chlorosis is, the facility with which hæmorrhages occur in the former, to such a degree indeed that it is one of its most characteristic symptoms. Why is there this constant tendency to hæmorrhage in scurvy?—and why is it so comparatively rare in chlorosis? Because in the former there is a modification of the blood totally different to what we observe in the latter. In scurvy the globules are not generally diminished to such an extent as in chlorosis, but the fibrine is considerably below its normal amount, and this has been found to be the case also in typhus fever of the adynamic or putrid kind, which, from a consideration of the alterations of the blood, as well as the general nature of the symptoms, was called by Bordeu *acute scurvy*.

Again, Professor Andral says he had long considered the fibrin of the blood to be deficient in quantity in scurvy, and he was enabled to verify this supposition in the month of April, 1841. A patient was admitted into the Hôpital de la Charité, with all the worst symptoms of the disease. He was bled, and the blood found to contain—119, globules; 86, solid matters of the serum; and only 1.6, of fibrin. Professor Andral further adds, that he has no doubt it will be found also that the fibrine of the blood is below its normal amount in all well-pronounced cases of purpura hæmorrhagica; and he affirms, that in a case of purpura, which resembled in its symptoms the most aggravated case of typhus, he found the blood continued in a state of fluidity.

Again, it may be asked, is there not some other alteration of the blood, which may produce this diminution in its normal quantity of fibrin? Before the fibrin diminishes, may there not be some other change of composition, of which the diminution of the fibrin is only a consequence? Majendie injected subcarbonate of soda into the veins of a living animal, and after death he found a "dissolution" of the blood. In individuals who have died from putrid fever or scurvy, where the blood is less coagulable than usual, some authors affirm that they have found a larger than normal amount of alkaline substances. Professor Andral in his researches has observed amongst other facts that the blood which contained the most free alkali was that taken from the scorbutic patient mentioned above, and this observation is in accordance with what M. Frèmy announced some years ago.

But these are not the only alterations of the blood observed in the case before us. It is evident from the symptoms that there is also a state of anæmia or diminution in the quantity of the globules, and with this condition it is also probable that the globules themselves are altered in structure and conformation. Professor Andral observes on this head, "It would be very interesting to know if the globules, at the same time that they diminish in number in anæmia, do not also alter in their structure, and if there is not a tendency to undergo, complete destruction. It appeared to him in two cases of chlorosis, that the globules had become much smaller than we generally observe them to be, at the same time a certain number had not their usual form, they were as if broken up and dispersed, and resembled fragments in the field of the microscope."

Again, it is very probable that we have also in this case, a diminution of albumen, with increase in the relative amount of watery constituents of the blood, of which the effusion into the cellular tissue is a clear evidence; for Andral says that patients never become dropsical from loss of fibrin, but from loss of albumen; and he asks whether it is a case of simple exosmosis, favoured by the diminished density of the blood, or is it rather the serum of the blood which escapes more easily into the cellular tissue, from being less charged with albumen, and consequently being less unctuous in its character, glides less readily along the inner surface of the vessels?

The difference we observe between a case of this kind and one of true sea-scurvy, would appear to be, that while in the latter we have merely (at least in the less advanced cases,) an increased amount of free alkali in the blood, with a diminution in its fibrin, in the former we have, in addition to this, a diminution both of the globules and the albumen.

These alterations of the blood may be well considered to have induced the symptoms, and are amply sufficient to account for the whole chain of morbid conditions observed in this case. Thus, the lack of fibrin, and the alteration in the structure of the globules, will

account for the effusion of the colouring matter under the skin, causing the "purpura," which is here merely a symptom, and not as Dr. Elliotson believes, a distinct disease; the deficiency of albumen, causing œdema of the legs, feet, &c., whilst the extremely impoverished condition of the blood in general would no doubt speedily induce dilatation of the heart, atrophy of the liver, vertigo, thickening of the skin, derangement in the digestive organs, sponginess of the gums, obstruction to the circulation in the superficial veins of the leg, &c. &c.

In considering the causes which may have produced this condition of the blood; we may ask if it is not probable that the deleterious nature of the food which the patient has taken may have contributed towards inducing it? The brown bread on the Continent often contains a large proportion of rye, and consequently also the ergot. Dr. Wright observes, that "the long continued use of the ergot often produces a cachectic state of the body, indicated by extreme muscular wasting and weakness, loss of appetite, frequent pulse, fœtor of the secretions and excretions, congestion of the alimentary mucous membrane, excessive contraction of the spleen, &c." But although this may have contributed in some degree towards the production of these alterations, it is evident thas the want of fresh animal and fresh vegetable substances, the long continued use of the same kind of food, and that in insufficient quantity, together with the irregular manner of living, was amply sufficient, in this case, to determine the accidents observed; and doubtless the frequent occurrence of diarrhœa, by removing the healthy constituents of the blood, would greatly accelerate the results.

Treatment.—Here the indications are very evident. In the first place, improve the condition of the blood; secondly, encourage the free circulation in the skin, and favour its return from the inferior extremities. The first indication is fulfilled by attention to diet, which must consist of fresh meat and fresh vegetables, in order to increase the quantity of fibrin in the blood; lemon juice to destroy the too large amount of free alkali in the blood; and afterwards give iron to improve the condition of the globules, and render the blood more invigorating.

To fulfil the second indication, we employ warm baths, to soften the integuments and determine the blood to the surface, friction with almond oil, &c.; and for the obstruction in the venous circulation, elevation of the legs, and bandaging from the foot to the hip.

Prognosis—Dr. Elliotson observes that this disease is of a chemical nature, if any one be so. In one sense the constitution is not at all in fault; all the fluids and all the solids appear to be changed; but we have only to give a different chemical state to the body, and the disease is cured. This may be true in a great number of cases, but Professor Andral says that nothing is more difficult than the definite cure of those diseases in which the blood is robbed in a slow and spontaneous manner, either of its globules, or its fibrin. We know how easy are relapses in young chlorotic females, and how often the symptoms are long in being entirely removed. In persons of still more advanced age, who become spontaneously anæmic, the production of the globules is still more difficult to obtain. As to scurvy, if it arises from evident external causes, it generally yields readily, when these influences no longer exist; but if it comes on spontaneously, it will generally resist every possible means we may employ. Again, the same author adds, "I have seen scurvy cured, but I have also seen a great number of cases in which, although the symptoms appeared to improve very greatly at intervals, they never entirely disappeared, and after gradually increasing, finally terminated fatally." In the case before us, although the patient appears to be perfectly cured, yet Professor Piorry affirms, that if on his dismission he is not very circumspect,—if he is not allowed sufficient wholesome food, and employment in the open air, &c., it is very evident, on considering the age of the patient, and the length of time the disease has continued, that he will be liable to a speedy relapse.

Paris, April 26, 1847.

PROVINCIAL
Medical & Surgical Journal.
WEDNESDAY, MAY 19, 1847.

It is with much satisfaction that we learn that Her Majesty's Government have consented to the appointment of a Select Committee of the House of Commons to investigate the subject of "Medical Registration and the state of the Law relating to the Practice of Medicine and Surgery" in this country. The second reading of Mr. Wakley's Bill, originally fixed for Wednesday, May 5th, and then for the following Monday, is again postponed to Monday, 31st, on which occasion will be brought forward a motion for referring the Bill to a select Committee.

Whatever views may be taken of the several provisions of the Medical Registration Bill, and of the manner in which it is proposed therein to carry out its objects, there can be no question that the two leading principles of the Bill,—1st the distinguishing of qualified from unqualified practitioners; and 2ndly, the giving to the qualified practitioner a general legal recognition, and sanction to practise, are equitable and sound, calculated to be of genuine service to the public, and deserving of the warm support of the profession. The inquiry into these questions cannot but be fraught with beneficial consequences, and we trust that no attempt which may be made in any quarter to shelve or otherwise defeat the motion, will be permitted to be successful.

Any equality of privilege actually possessed by, or proposed to be bestowed on, the entire profession, or any section of it, or corporate or

other body belonging to it, on the ground of equality of qualification must, under existing circumstances, be futile in the extreme. To look to England alone, what can be more heterogeneous as respects qualification, than the elements of which either of the Royal Colleges of Physicians and Surgeons are composed; or to take non-corporate bodies, than those of the Provincial Medical and Surgical Association, or of the National Institute of Medicine, Surgery, and Midwifery. Equality of qualification, were it attainable, could not be preserved for a single week; but a given sufficient amount of qualification is attainable, and ought to found the ground-work of all future admissions within the pale of the profession, while for the past, the possessers of genuine qualification, duly certified to by any British University, or corporate body empowered to grant licenses to practise, are entitled to be legally recognized as such, and registered as members of the profession, and of the several sections of it to which they may belong,—it being always to be borne in mind, that between the very lowest in point of attainments of any individual so qualified, and the highest in point of pretension of any of the unqualified mountebanks who live by the gullibility of the public, there is a vast and immeasurable distance, which ought to be distinctly marked.

Proceedings of Societies.

BATH PATHOLOGICAL SOCIETY.

First Meeting, October 5th, 1846, Mr. Norman in the Chair.

Case I.—*Injury of the head from a fall; insensibility coming on gradually, and death following in forty-eight hours after the accident; the right pupil dilated and immoveable. Dissection:—A large clot beneath the dura mater; a small coagulum on the right optic nerve after it leaves the commissure.*

Mr. Gore exhibited the brain of a woman who died in consequence of a fall on her head; the part of the head which received the injury was the right parietal protuberance. She remained conscious, and with the power of motion for some hours after the accident; insensibility gradually supervened, and she continued comatose until death, which took place forty-eight hours after the receipt of the injury. The right pupil was dilated and immoveable. On dissection after death a large coagulum, two or three ounces, was found beneath the dura mater, in the right parietal region; the precise source of the blood did not appear. On the right optic nerve, after it leaves the commissure, there was found a small coagulum. Mr. Gore remarked on the importance of one of the symptoms of this case, as guiding to a just diagnosis—namely, the consciousness of the patient continuing for some time after the accident, total insensibility then following, marking the gradual development of a compressing cause, which in such a case could be no other than hæmorrhage. The situation of the injury, and the absence of tenderness over the course of the middle meningeal artery, Mr. Gore considered sufficient to contraindicate operative interference.

Case II.—*Frequent vomiting, with pain referred to the region of the stomach, occurring at from two to three hours after taking food. Dissection:—Evidences of inflammation of the duodenum near the pylorus, and partial atrophy of both kidneys.*

Mr. Hunt exhibited part of the duodenum, including the pylorus, the kidneys, and part of the uterus, of a woman who had been delivered about ten days before death. She first came under Mr. Hunt's care in February, 1846, at which time her symptoms were, severe and constant vomiting, with pain referred to the region of the stomach, for the most part occurring at from two to three hours after taking food, with considerable emaciation. These symptoms continued more or less up to the period of death, which took place in September. On dissection, the mucous membrane of the duodenum near the pylorus was found much thickened, and admitted of being easily torn off. One of the kidneys was greatly atrophied, and the other slightly so, apparently having undergone granular degeneration in different degrees. The urine had not been examined. The uterus was merely exhibited in order to illustrate the condition of that viscus at the above mentioned period after delivery.

Case III.—*Frequent vomiting, with gradual emaciation; no pain, but some difficulty of swallowing. Dissection:—Soft cancer involving the cardiac orifice of the stomach.*

Mr. Norman exhibited the œsophagus and stomach of a man who had been for some months under his care, at first with symptoms somewhat equivocal in their nature, but for some time before death the existence of cancerous disease of the cardiac orifice of the stomach was diagnosed. When the patient first came under Mr. Norman's care, he was suffering from constant vomiting on taking food, attended with gradual emaciation. No tumour could be felt, and he suffered no pain. There was some difficulty in swallowing. A full-sized œsophagus bougie was passed, which met with some obstruction at the junction of the pharynx with the œsophagus; this, with the other symptoms, rendered the idea of stricture probable, which was further confirmed by finding that the passage of the instrument was attended with marked relief to the vomiting, and also to the difficulty of swallowing. Matters went on thus until within a month of the patient's death, when it was found that the bougie would no longer pass into the stomach, in consequence of obstruction at the cardiac orifice. On dissection after death, the lower end of the œsophagus and the cardiac end of the stomach were found involved in an extensive cancerous deposit, of the soft or encephaloid kind. The disease had not attacked any other organ of the body. The cause of the obstruction to the passage of the bougie at the junction of the pharynx and œsophagus, was found to be an ossified

condition of the thyroid cartilage, by which the œsophagus was pressed backwards, and on one side.

Second Meeting, November 2nd, 1846.

Mr. NORMAN in the Chair.

CASE IV.—*Injury of the spine from a fall; complete paralysis below the seat of injury; death on the eighth day. Dissection:—Fracture of the laminæ of the two last cervical and upper dorsal vertebræ; effusion of blood beneath the dura mater, and softening of the substance of the cord.*

Mr. Brown exhibited part of the spinal column and cord of a man who had died in consequence of an injury received by falling on the lower part of his neck, from a height of about seven feet. He was admitted into the hospital twenty-four hours after the accident, and died on the eighth day. On admission there was perfect paralysis of the lower extremities, both as regards sensation and motion; tickling of the soles of the feet did not induce any reflex action; he had lost all power over the bladder and rectum, so that the fæces passed involuntarily, and the urine was retained; about two quarts of highly alkaline urine was drawn off after his admission. Priapism in this case was a troublesome symptom, at times interfering with the introduction of the catheter. The breathing was altogether diaphragmatic; the intercostal muscles being quite paralysed; strong pressure over the seat of injury caused considerable pain. On dissection, there was found an oblique fracture extending through the laminæ of the two last cervical and upper dorsal vertebræ, the spinous process of the seventh cervical vertebra being detached at its junction with the laminæ; blood was effused, both external to, and beneath, the dura mater, and the substance of the cord was softened opposite the seat of injury. Mr. Brown remarked regarding priapism, which was present in this case, that on making inquiry of Dr. Tunstall, at the Bath Hospital, he found it to be a frequent and troublesome symptom in the cases of paraplegia which came under treatment in that institution.

CASE V.—*Scrofulous disease of the eye-ball, simulating malignant disease.*

Mr. Soden brought a child before the Society, for the purpose of exhibiting a peculiar pathological condition of one eye, in which the appearances presented were very much such as would lead to the idea of malignant disease of the eye-ball, but which in fact consisted of a scrofulous deposit in the iris, with a series of purple vesicles surrounding the choroid ligament.

CASE VI.—*General anasarca; albuminous urine. Dissection:—Granular kidney.*

Dr. Daniell exhibited a kidney in the second stage of granular degeneration, taken from the body of a young woman who had died universally anasarcous. The disease ran a short and rather acute course; the urine during the whole time was of low specific gravity and highly albuminous. On dissection, the cortical substance of the kidney was found thicker than natural, much blanched in colour, and studded throughout with very distinct yellow granulations; the tubular structure was free from deposit, and of natural colour; the whole of the abdominal viscera were much blanched in appearance.

CASE VII.—*Craniotomy in a case of deformed pelvis; a considerable portion of brain removed; the child cried after delivery.*

Mr. King related the circumstance of craniotomy having been performed in a case of deformed pelvis, a large portion of the child's brain being removed, and the head afterwards drawn down. The child, notwithstanding, cried after birth.

Third Meeting, December 7th, 1846.

Mr. NORMAN in the Chair.

CASE VIII.—*Dysentery and abscess of the liver. Dissection:—Sloughing of the mucous and muscular coats of the colon; several large abscesses in the liver.*

Dr. Budd exhibited the colon and liver of a man who died of dysentery and abscess of the liver. Drawings of the recent parts were also exhibited. The patient had been a railway labourer, was a finely-formed athletic man, 28 years of age. Before his illness he had enjoyed robust health. He was admitted into the hospital labouring under severe and clearly-marked symptoms of dysentery, and subsequently abscess of the liver was diagnosed. On dissection after death, the whole of the colon was found in a state of intense inflammation, the mucous and muscular tissues in a sloughy condition, with two large ulcerated openings into the peritoneal cavity, one situated in the sigmoid flexure, and the other higher up. The liver contained several large abscesses. Dr. Budd remarked on the comparative rareness of such severe dysenteric disease in this country, and also called attention to the case as an example of abscess in the liver following the formation of pus in the colon; the previously robust and healthy condition of the man, with the laborious occupation he had followed, precluding, in Dr. Budd's opinion, the idea that the liver disease had preceded the dysentery.

CASE IX.—*Abscess of the Liver.*

Mr. Boult read the history of a case of primary abscess in the liver. The abscess was punctured and the patient recovered. This paper appeared in full in the first number of this Journal for the present year.

CASE X.—*Obstinate constipation and death; morbid appearances in the small intestine unsatisfactory.*

Mr. Field exhibited a portion of the ileum taken from the body of a man who died under the following circumstances:—He complained of pain in the left iliac region, not severe, nor increased by pressure; his bowels were obstinately constipated, and resisted all attempts to promote their action, until within a short period of death, when they acted freely. He was bled; the blood was slightly buffed. On dissection, the seat of the disease was found to be a portion of the ileum some distance above the caput cæcum; that portion of the small intestine above the disease presented nothing remarkable in appearance, whilst the implicated portion was considerably dilated; the mucous coat much injected, and of a dark colour; the

peritoneal covering was natural. Mr. Field remarked on the obscurity of this case, both as regards its symptoms and *post-mortem* appearances, and questioned whether it ought to be considered as a case of ileus, as described by Dr. Abercrombie, or one of inflammation, affecting the mucous and muscular coats, without involving the peritoneal.

CASE XI.—*Symptoms of inflammatory fever, with more or less of dyspnœa; rather sudden death. Dissection.—Fluid in the serous cavities; some degree of obstruction of the left side of the heart.*

Mr. Bush exhibited a heart taken from the body of a young man, about 24 years of age, who applied to him some weeks before death, sufferiug under symptoms of asthma; he was afterwards attacked with inflammatory fever, from which he seemed to be recovering, when he fell on getting out of bed, complained of much pain, and died in twenty minutes. On dissection, both lungs were found much congested, and both pleural cavities contained a quantity of bloody serum, as did also the pericardium. On cutting across the aorta, a quantity (probably one or two drachms,) of pus-like matter flowed out, along with some fluid blood; on laying open the left ventricle, there was found a rather firm fibrous band, extending across the base of two of the aortic valves, in such a way as must, to a certain extent, have impeded the flow of blood into the aorta; in other respects the heart was natural.

CASE XII.—*An example of extensive intus-susception.*

CASE XIII.—*A case of extreme cirrhosis of the liver.*

Dr. Budd exhibited a preparation and drawings of the parts when recent, of a case of intus-susception, when the whole of the transverse colon, even to its junction with the ileum, had passed into the sigmoid flexure, symptoms of strangulation came on, and death followed in seven days. Also a case of extreme cirrhosis of the liver. The preparation and drawings were exhibited. There was not much known concerning the history of the man from whom the specimen was taken, except that he had been a large consumer of raw spirit. As to the nature of cirrhosis, Dr. Budd remarked that it consists essentially in inflammation and thickening of the capsule of Glisson, set up in consequence of the circulation through the liver of the alcoholic fluid. This gives rise to pressure on, and atrophy of, the vascular structure of the organ, leading to imperfect nutrition, by pressure on its nutrient vessels; ascites, by pressure on the portal system; and occasionally jaundice, from the same cause acting on the bile-ducts.

SHEFFIELD MEDICAL SOCIETY.

Sixth Session, Thirteenth Meeting, March 18th, 1847.

The President, Mr. TURTON, in the chair.

The President exhibited a portion of the left superior maxilla of a girl, aged 8, which had exfoliated as a consequence of fever, of a typhoid character. In the treatment no mercury was used. The case terminated very well.

FATTY TUMOUR: ÆTHER-INHALATION.

Mr. H. Jackson exhibited a large tumour, removed from the arm of a farm-labourer, aged 66. Its existence had been detected accidentally ten years ago, and it was then as large as a hen's egg, and had gradually increased. It never has given him pain, but he had been alarmed by hæmorrhage taking place from the most depending portion of it on two different occasions within the last two years. It covered the brachial artery about two thirds of its course. The vapour of æther was used, and operated in two minutes. The patient complained of no pain. On cutting into the tumour it was found to be a fatty mass, having in its centre a small cavity about the size of a common nut, which was filled with light-coloured pus. The bleeding had taken place from a vein which had passed over a small ulcer, arising from the distention of the integument. The patient was doing well.

SCIRRHOUS BREAST: EFFECTS OF ÆTHER.

Mr. H. Jackson exhibited a scirrhous breast which he had removed from a woman, aged 55. The patient was a stout-looking woman, married, but had never borne children; of very irregular habits. The æther operated in three minutes, producing all the effects described as those of æther. The prostration was very extreme, and had continued so up to this, the fifth day. The patient had presented occasional symptoms of hysteria since the operation, but Mr. Jackson considered her to be in danger from the effect of the æther.

Mr. H. Jackson exhibited to the Society a working model of a grinding-wheel, exhibiting the means by which it was intended to carry off the particles of dust and steel in the process of grinding, and thereby diminish the danger attendant upon that trade. The model was constructed by the late J. H. Abraham, F.L.S., who had devoted a considerable portion of time to the subject; it is the property of the Literary and Philosophical Society of Sheffield.

PERITONITIS FOLLOWING FEVER: FÆCAL ABSCESS: INTERNAL STRANGULATION.

Mr. H. Jackson read a communication from Mr. W. C. Russell, of Bawtry, of the following case:—A boy, aged 15, presenting the strumous diathesis, was seized with fever, of a very low character, (then epidemic in the neighbourhood, and from which he with difficulty recovered,) on the 5th of November, 1845. On the 13th of January following, symptoms of peritoneal inflammation appeared, which gave way to treatment. On the 20th he complained of great pain and tenderness of the abdomen, which were quickly followed by tympanites. These symptoms gave way, and the abdomen became soft, but a circumscribed tumour, from four to five inches in diameter, remained situated midway between the superior spinous process of the ilium on the right side and the umbilicus. On the 29th an opening was made into the tumour, on which a quantity of very offensive gas escaped, followed by collapse of the tumour, and shortly afterwards by a copious discharge of pus, in which were some small particles of fæculent matter. The wound was kept open by a canula, and for several weeks an abundant

discharge continued; it healed, however, about the 1st of April. The boy rapidly improved in health, and went to work in the fields. In consequence of some protrusion at the cicatrix, an umbilical truss was applied, which answered the desired end. On the 27th of September he was suddenly seized with violent pain in the abdomen, vomiting and obstruction of the bowels. Treatment here completely failed. Little more than two ounces of fluid could be injected; opium appeared to palliate; the vomiting continued from the 27th; on the 30th it became stercoraceous, lumps of fæces the size of walnuts being ejected from the stomach. No evacuation having taken place from the 29th of September, on the 12th of October half an ounce of quicksilver was administered, but without any visible effect; the stercoraceous vomiting continued, accompanied by violent tormina and every indication of intus-susception. November 1st, the bowels began to act very freely, the quantity passed was enormous; there was no appearance of the quicksilver; the vomiting still continued. The boy lingered until November 13th, and then sank in a most extreme state of emaciation.

On inspection *post mortem*, numerous adhesions were found in every direction. The stomach small and its coats attenuated; it contained some small portions of fæculent matter; the mucous lining was ash-coloured but not ulcerated. The convolutions of the intestine were glued together, and from several points a fæculent discharge exuded. The mesenteric glands were much enlarged; two of them about the size of pigeon's eggs, were in an advanced stage of suppuration. On tracing the ileum from the jejunum to the extent of about twelve inches, it was found to terminate in a *cul de sac*, formed by a strong band of false membrane, an inch and a half in length, firmly attached at one point to the jejunum, and at the other to the descending colon, preventing peristaltic action, and actually strangulating the bowel. This portion of intestine was almost black, as if in a state of gangrene, but the coats were very firm and the quicksilver had accumulated here. At this point an abscess had formed implicating the sigmoid flexure of the colon as well as the ileum. The abscess having burst some days before death, will account for the emptying of the larger intestines. The pelvic portion of the ileum was almost embedded in enlarged mesenteric glands in a state of suppuration. The intestine including the jejunum, and about twelve inches of ileum, had become so much thickened that it resembled the structure of the rectum, while the ascending and transeverse colon had become so much attenuated as to resemble ileum. The gall-bladder was of inordinate size, and contained four ounces of thick dark-coloured bile. Nothing remarkable in the other viscera.

CHRONIC INFLAMMATION OF THE CÆCUM AND COLON.

Mr. Storrs, of Doncaster, read a paper on chronic inflammation of the mucous membrane of the cæcum and colon. The disease which he was anxious to describe, differed from dysentery, inasmuch as it is unattended with the same amount of constitutional disturbance; it is a chronic form of disease, the constitutional symptoms of which are in general very slight, and only become aggravated through neglect, or harsh and improper treatment. The symptoms of the slow form of inflammation of the textures in question, are often so slight as to be at first unobserved. There is occasional discharge of mucus from the bowels, without any purging; the stools are often perfect in form and consistence, but partially coated with mucus, or followed by flakes of mucus, which come away without any straining or tenesmus; occasionally the mucus will appear in small lumps, not unlike lumps of fat, at other times it assumes the form of the finger of a glove. This mucus is quite uncoloured, either by the fæces or by the admixture or infiltration of blood; sometimes there are scybalæ discharged with the mucus, but more frequently the stools are of the natural appearance and consistency. The medical man is seldom consulted at this early stage of the disorder; soon, however, the symptoms are sufficiently marked to call for medical aid. Then slight tenderness on pressure is detected in the cæcal region, extending upwards towards the liver and duodenum, and downwards towards the pelvis and pubes; the pulse is soft and weak, and slightly quickened; the tongue is somewhat coated, and more or less red at the tip and edges; the skin, especially of the hands, is moist, soft, porous, and indicative of a considerable degree of general debility; the countenance and appearance of the lips and eyelids, especially in females, is more or less anæmic; the nervous system is highly irritable, and the action of the heart is increased on slight exertion. Sometimes there is more or less spasmodic pain generally throughout the abdomen, and not unfrequently the symptoms are ascribed to an aggravated state of chronic dyspepsia; occasionally the stools are very fœtid, dark, and disagreeable. As the inflammatory action of the intestine advances, there is increased abdominal tenderness, and the symptoms then assume a character produced by a mixture of nervous and inflammatory disturbance. The predisposing cause of the disease, Mr. Storrs considered to be a relaxed and atonic state of the vascular system, and a highly irritable state of the nervous; the exciting causes,—torpor of the bowels, scybalæ, drastic purgatives, and repeated errors of diet. It may not unfrequently be connected with suppressed or deficient menstruation, suppressed hæmorrhoidal discharges, and tight lacing. It is well to examine the stools in all cases of dyspepsia, as the condition above described may thus be detected when little suspected. When discovered, all drastic purgatives are to be avoided. A few leeches, followed by blisters, are advisable, when there is any abdominal tenderness, due care being taken to husband the powers of the patient, which are soon depressed in this form of disorder. When the inflammatory action is sufficiently subdued, the tone of the system is most rapidly restored by a continued exhibition of the citrate of iron, this preparation being generally preferred by the patient. Mr. Storrs strongly recommended iron in some form or other, believing it to produce, not only a general and constitutional effect, but also some degree of local power as an astringent.

Smart doses of calomel and scammony, followed by castor oil, are useful when scybalæ are suspected; in other cases, drastic purgatives should be avoided, and mild injections substituted for them. When the inflammatory symptoms do nor yield to leeches and blisters, the Linimentum Hydrargyri is useful.

Mr. Storrs then detailed several cases illustrative of the condition above described.

Miss W., a delicate lady, about 28 years of age, had suffered for a considerable time from indigestion, pain at the epigastrium after eating, and loss of appetite, and which continued in spite of treatment. After a time great tenderness on the right side of the abdomen came on, accompanied now and then with severe spasmodic pain; the pulse was quick and soft; the palms of the hands wet and clammy; sometimes very hot, but more frequently cold. As the disease advanced severe faintings and hysterical symptoms came on; the countenance, from being florid, became sallow, and the lips pale, and there existed a high state of irritability and debility of the whole system. On inspecting the motions a large portion of mucus about six inches in length, and still preserving the form of the bowel, though collapsed, was detected; the stools were otherwise healthy. Leeches and blisters were successively applied to the tender portion of the abdomen, and when the inflammatory symptoms were sufficiently subdued by these means and gentle aperients, a preparation of iron was given for some time, under which the patient gradually, though slowly, recovered. Several portions of mucus were voided, sufficiently consistent to retain the form of the bowel, after the one first observed, but this discharge quite ceased after the iron had been administered for a short time. There was some degree of irregularity in menstruation both before and during the attack of the disorder.

The other cases detailed were very similar to the one just related. Mr. Storrs concluded his paper by remarking on the frequency of the disorder, particularly in delicate females and amongst the poor and ill fed, and reiterated his conviction of the value of iron as a remedy in the disease. Though he had had no opportunity of making any *post-mortem* examinations in this disease, he considered it far from improbable that many of the disorganizations of the cæcum and colon, such as ulceration, thickening, and contraction of tunics, are referable to a long continuance of the condition described.

A CASE IN WHICH THE DIPLOMA OF THE COLLEGE OF SURGEONS WAS LATELY OBTAINED UNDER FALSE PRETENCES, AND OF WHICH THE PARTY WAS DEPRIVED AFTER A DUE INVESTIGATION.

TAUNTON AND SOMERSET BRANCH OF THE PROVINCIAD MEDICAL AND SURGICAL ASSOCIATION.

At a Council meeting held on Thursday, May 6th, 1847,

Resolved,—

"That a verbatim copy of the whole of the correspondence connected with James Dore Blake's diploma be forwarded for insertion to the Editor of the *Provincial Medical and Surgical Journal*."

"FRANCIS HENRY WOODFORDE, M.D.,
President.

"CHARLES HAYES HIGGINS, F.R.C.S.,
Honorary Secretary.

"Taunton, May, 1847."

CORRESPONDENCE.

Taunton, July 8, 1846.

Sir,—I am instructed by the members of the Taunton and Somerset Medical Association to forward the inclosed memorial to the President and Council of the Royal College of Surgeons of England through you.

I am, Sir,
Your obedient servant,
CHARLES HAYES HIGGINS,
Honorary Secretary.

To Edmund Balfour, Esq., Secretary to the Royal College of Surgeons.

Taunton, June 25, 1846.

To the President and Council of the Royal College of Surgeons of England.

Gentlemen,—We, the undersigned, being Fellows and Members of the Royal College of Surgeons of England, residing in the town and neighbourhood of Taunton, and being desirous of upholding the dignity and respectability of our College, feel it our duty to draw your attention to the fact, that a Mr. James Dore Blake, who until May 1845, and for a period of about thirteen years previously, was a retail pastry-cook and confectioner in that town, has lately obtained the diploma of the College of Surgeons; and to represent to the Council, as well the scandal to our College which such a circumstance is calculated to produce, as the extreme hardship to those members of the College, who by the regulations of the College have been obliged to go through a lengthened period of regular study, and a great deal of expense, in order to obtain a diploma which has been granted to a retail shopkeeper of thirteen years' standing, after a period of only one year of alleged study, and at a comparatively trifling outlay of money.

And we farther call upon you, the President and Council of our College, to prosecute such inquiries into the testimonials and certificates produced by Mr. James Dore Blake, before the Court of Examiners, as shall place the matter in a position satisfactory to all concerned in upholding the honor and credibility of the College of Surgeons.

We have the honor to subscribe ourselves,
Your obedient servants,

ROBERT RUSSEL SEWELL, Bridgewater.
FRANCIS HENRY WOODFORDE, M.R.C.S.E., Taunton.
WM. M. KELLY, M.R.C.S.E., Taunton.
GEORGE CORDWENT, M.R.C.S.E., Taunton.
JOHN PRANKERD, M.R.C.S.E., Langport.
H. W. RANDOLPH, M.R.C.S.E., Milverton.
HENRY FOOT LING, M.R.C,S.E., Stogumber.

CHARLES HAYES HIGGINS, F.R.C.S.E., Taunton.
CHARLES HUGO, M.R.C.S.E.
JAMES DYER, M.R.C.S.E., Creech.
WILLIAM BEADON, M.R.C.S.E.
WILLIAM CATLETT, M.D., M.R.C.S.E.
HENRY ALFORD, F.R.C.S.E.
FRANCIS WELCH, F.R.C.S.E.
FRANCIS FOSTER, M.R.C.S.E.
HENRY LIDDON, M.R.C.S.E.
JOHN LIDDON, F.R.C.S., Eng.
C. H. CORNISH, F.R.C.S., Eng., Wellington.
WILLIAM COLLARD PYNE, M.R.C.S.E., Wellington.
W. C. PYNE, Jun., M.R.C.S.E., Wellington.
ALBERT LANGLEY, M.R.C.S., Eng.
GEORGE KIDGELL, M.R.C.S.E., Wellington.

Royal College of Surgeons of England,
July, 1846.

Sir,—I have laid before the Council of this College the memorial enclosed in your letter of the 8th instant, signed by five (four,)* Fellows, and eighteen other Members of the College, residing in the town and neighbourhood of Taunton, drawing the attention of the Council "to the fact, that a Mr. James Dore Blake, who until May, 1845, and for a period of about thirteen years, was a retail pastry-cook and confectioner in that town, has lately obtained the diploma of the College of Surgeons," and calling upon "the Council to prosecute such enquiries into the testimonials and certificates produced by Mr. James Dore Blake, before the Court of Examiners, as shall place the matter in a position satisfactory to all concerned in upholding the honor and credibility of the College of Surgeons." And I am directed by the Council to transmit to you copies of the several certificates handed in by Mr. Blake, prior to his admission to examination for the diploma of this College.

I am, Sir,
Your most obedient servant,
EDMUND BALFOUR, Secretary.

Charles Hayes Higgins, Esq.,
Honorary Secretary.
Taunton and Somerset Medical Association.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

CERTIFICATES OF EDUCATION.

Preliminary Education

"If the candidate began the study of his profession previously to his attendance on lectures or hospital practice, let it be here stated, and whether the same was by an apprenticeship, or in what other manner."

[*Printed Certificate filled up.*]

"It is hereby certified, that Mr. J. D. Blake has been employed in the study of medicine during the last ten years, about five of which he acted with me, and under my directions, and to my perfect and entire satisfaction.

"Dated 2nd day of April, 1845.

"Signed W. H. TROTMAN, Surgeon, R.N."

(See also letters appended.)

Anatomy and Physiology.

"This and the following certificate are divided into two parts, as the regulations of the College require, that the attendance should have been during two distinct Anatomical Sessions, of six months each, and comprising at least 140 lectures, and 100 demonstrations."

"It is hereby certificed, that Mr. Jno. Dore Blake very diligently attended my lectures on Anatomy and Physiology, at the School of Medicine, Charlotte Street, Bloomsbury, from the 1st day of May, one thousand eight hundred and forty-five, to the 1st day of August, one thousand eight hundred and forty-five, and that this course or session included seventy lectures.

"Dated 1st day of April, 1846.

"Signed G. D. DERMOTT."

"It is hereby certified, that Mr. Jno. Dore Blake very diligently attended my course of lectures on Anatomy and Physiology at the school of Charlotte Street, Bloomsbury, from the 1st day of October, one thousand eight hundred and forty-five, to the 1st day of April, one thousand eight hundred and forty-six, and that this session included 142 lectures.

"Dated 1st day of April, 1846.

"Signed G. D. DERMOTT."

Demonstrations and Dissections.

"It is hereby certified, that Mr. Jno. Dore Blake very diligently attended my Anatomical Demonstrations at the School of Medicine, Charlotte Street, Bloomsbury, from the 1st day of May, one thousand eight hundred and forty-five, to the 1st day of August, one thousand eight hundred and forty-five; that this session included fifty demonstrations, and that he diligently dissected during the same period.

"Dated 1st day of April, 1846.

"Signed G. D. DERMOTT."

"It is hereby certified, that Mr. Jno. Dore Blake very diligently attended my Anatomical Demonstrations at the School of Medicine, Charlotte Street, Bloomsbury, from the 1st day of October, one thousand eight hundred and forty-five, to the 1st day of April, one thousand eight hundred and forty-six; that this session included upwards of 100 demonstrations, and that he diligently dissected during the same period.

"Dated 1st April, 1846.

"Signed G. D. DERMOTT."

Surgery.

"This certificate also is divided into two parts, as the regulations of the College require that the attendance on surgical lectures should have been during two distinct periods or seasons, each comprising not less than sixty lectures.

"It is hereby certified, that Mr. Jno. Dore Blake very diligently attended my lectures on Surgery at the School of Medicine, Bloomsbury, from the 1st day of May, one thousand eight hundred and forty-five, to the 1st day of

* The number of Fellows appears to be five, from the list of signatures.—[Ed.]

August, one thousand eight hundred and forty-five; and that this course included forty lectures.

"Dated 1st day of April, 1846.

"Signed G. D. DERMOTT."

"Mr. J. D. Blake also very skilfully performed many of the capital surgical operations on the dead body under my superintendance."

"It is hereby certified that Mr. Jno. D. Blake very diligently attended my lectures on Surgery, at the School of Medicine, Bloomsbury, from the 1st day of October, one thousand eight hundred and forty-five, to the 1st day of April, one thousand eight hundred and forty-six; and that this Session included eighty lectures.

"Dated 1st day of April, 1846.

"Signed, G. D. DERMOTT."

Practice of Medicine

"Required to occupy a period of six months, and to comprise not less than sixty lectures."

"It is hereby certified that Mr. J. D. Blake very diligently attended my lectures on the Practice of Medicine, at the School of Medicine, Charlotte Street, from the first day of October, one thousand eight hundred and forty-five, to the first day of April, one thousand eight hundred and forty six; and that this course included 100 lectures.

"Dated 1st day of April. 1846.

"Signed, J. C. B. ALDIS, M.D."

Chemistry

"Required to occupy a period of six months, and to comprise not less than sixty lectures."

"It is hereby certified that Mr. James D. Blake attended my lectures on Chemistry, at the School of Medicine and Surgery, Charlotte Street, from the first day of October, one thousand eight hundred and forty-five, to the first day of April, one thousand eight hundred and forty-six; and that this course included sixty lectures.

"Dated 1st day of April, 1846.

"Signed, JOHN RYAN."

Midwifery

"Required to occupy a period of six months, and to comprise not less than sixty lectures."

"It is hereby certified that Mr. James D. Blake, attended my lectures on Midwifery, at the School of Midwifery, Russel Place, from the first day of May, one thousand eight hundred and forty-five, to the last day of December, one thousand eight hundred and forty-five; that this course included upwards of one hundred lectures, and that he has attended several midwifery cases under my direction.

"Dated 13th day of February, 1846.

"Signed, J. H. DAVIS."

Botany

"Required to occupy a period of three months, and to comprise not less than thirty lectures."

"It is hereby certified that Mr. J. D. Blake has diligently attended my lectures on Botany at the School of Medicine, Charlotte Street, from the fifth day of May, one thousand eight hundred and forty-five, to the 24th day of July, one thousand eignt hundred and forty-five; and that this attendance included thirty lectures.

"Dated 29th day of July, 1846.

"Signed B. CLARKE."

Materia Medica

"Required to occupy a period of three months, and to comprise not less than thirty lectures."

"It is hereby certified that Mr. James Dore Blake, attended my lectures on Materia Medica, at the School of Medicine, Charlotte Street, Bloomsbury, from the 2nd day of October, one thousand eight hundred and forty-five, to the 1st day of April, one thousand eight hundred and forty-six; and that this course included eighty lectures.

"Dated 1st day of April, 1845-46.

"Signed GEO. SMITH, M.D."

Hospital Surgical Practice.

"This certificate is divided into two parts, in case the attendance should have been at more than one Hospital, or at the same Hospital, but not during consecutive periods."

"We hereby certify that Mr. James D. Blake attended the Surgical practice of University College Hospital from the 1st day of May, one thousand eight hundred and forty-five, to the 1st day of May, one thousand eight hundred and forty six."

"Dated 1st day of May, 1846.

"Signed, ROBERT LISTON.

"W. Long." "R. QUAIN,

"Surgeons to the Hospital."

Certificate of Age.

"In the event of much difficulty or expense in obtaining the certificate of age on this sheet, it may be procured separately and appended thereto."

Declaration.

"This declaration to be signed by the candidate at the College, in the presence of the Secretary or other officers."

"I, James Dore Blake, candidate for the diploma of the College of Surgeons of England, do hereby solemnly and sincerely declare, that I am twenty-two years of age;—that I have been engaged during five years in the acquirement of professional knowledge;—that I have regulalry attended the hospital practice, and the several courses of lectures required by the regulations of the College;—and that the foregoing certificates are in every respect correct and true.

"JAMES DORE BLAKE.

"Dated this 4th day of May, 1846.

"Witness H. P. Gregg."

"Taunton, Feb. 20, 1846.

"I hereby certify that Mr. James D. Blake, of Taunton, was born in Salisbury, on the 18th day of November, one thousand eight hundred and five.

"R. QUAIN."

MEMORIAL SECOND.

To the President and Council of the Royal College of Surgeons of England.

Gentlemen,—Some time since, a memorial signed by four Fellows and nineteen other Members of the College of Surgeons was presented to you, touching the diploma of a Mr. James Dore Blake, for many years and until May, 1845, a retail shopkeeper, &c., in the town and neighbourhood of Taunton, Somerset. In reply to this memorial you were pleased to transmit through the Secretary of the College, authentic copies of the testimonials and certificates, in consideration of which Mr. Blake was admitted to an examination, and subsequently obtained from you a diploma.

Having given these testimonials and certificates full consideration and a careful examination, we, your memorialists, beg to submit, that in *three particulars* they are at variance with the regulations and requirements laid down by the College authorities for the observance of candidates of Mr. Blake's (supposed) standing; and we beg respectfully to call your attention to this circumstance, believing as we do that it is calculated to throw great discredit upon our own diplomas, and to prejudice the respectability of our College.

By the regulations of the Council respecting the professional education of candidates for the diploma, dated March 14th, 1835, candidates are required "to bring proof," amongst other matters, of having been engaged five years in the acquirement of professional knowledge; of having studied anatomy and physiology by attendance on lectures and demonstrations, and by dissections, *during two anatomical seasons.**

It is moreover stated, that "certificates will not be received on more than two branches of science, from one and the same lecturer; but anatomy and physiology, demonstrations and dissections, materia medica and botany, will be repectively considered as one branch of science."

Now, upon referring to Mr. Blake's certificates, we find the following points upon which the regulations of the College appear to have been avoided or neglected:—

And first, as to certificates of the period or duration of professioual education, we can discover only certain loose letters from various persons, referring to a period

* An anatomical season is understood to *extend from October to April inclusive, and to comprise at least* 140 *lectures on Anatomy and Physiology, and at least* 100 *demonstrations, &c.*, exclusive of dissections, of which distinct certificates are required.

of about ten years; whereas the College authorities require that it should be stated "whether" such professional education "*was by an apprenticeship, or in what other manner.*" And on this point we beg farther again to draw your attention to the fact, that from the year 1830, to the 1st of May, 1845, Mr. Blake was actively engaged as a retail tradesman, his career during that time having been as follows:—

From 1830, or thereabouts, until December, 1839, Mr. Blake was *personally* engaged as a retail pastry-cook, in the town of Taunton. At that date he embarked in co-partnership with a Mr. Richards, of the same town, in an iron foundry, taking an active share in his new business. From Mr. Richards Mr. Blake separated, somewhere about March, 1841, when he opened a pastry-cook's shop in the city of Bristol, where he remained until September, 1842, combining with the duties of his shop the study of homœopathy, under a Mr. Trotman, an homœopathic practitioner in that city, and from whom a certificate was received at the College, as proof of Mr. Blake's professional education. From September, 1842, to December, 1843, Mr. Blake was occupied in smelting iron ore for Sir Thomas Lethbridge, residing in the immediate neighbourhood of Taunton. And finally, in December, 1843, or January, 1844, he returned to Taunton, having purchased the business of a Mr. Hitchcock, a retail pastry-cook, and in which business he was constantly and personally engaged, until May, 1845, combining, as at Bristol, with the duties of his shop, the study and practice of homœopathy. In May, 1845, he removed to London, and on the 8th of May, 1846, he obtained his diploma, and is now a professed homœopathic practitioner at Taunton.

In the second place we find that instead of two anatomical seasons, each extending "from October to April, inclusive," and comprising at least 140 lectures, 100 demonstrations, &c. &c. Mr. Blake's certificates only shew attendance on the required studies during one winter season, of 140 lectures, and one summer season of three months, comprehending only 70 lectures, on anatomy and physiology; and one winter season of demonstrations, of 100 demonstrations; and one summer ditto, of 50 demonstrations.

And lastly, we find that Mr. Blake has been permitted to hand in certificates of lectures on *three distinct* branches of science, delivered by one and the same person, viz., on anatomy and physiology,—on demonstrations and dissections, and on surgery.

Having pointed out these circumstances, we beg to commit the matter into your hands, trusting that you will cause such inquiries to be instituted, as in the words of our former memorial, "shall place the matter in a position satisfactory to all concerned in upholding the honour and credibility of the College of Surgeons."

Signed by desire and on behalf of the former Memorialists and of the Members generally of the Taunton and Somerset Branch of the Provincial Medical and Surgical Association.

FRANCIS HENRY WOODFORDE,
M.D., M.R.C.S., President.

CHARLES HAYES HIGGINS, F.R.C.S.E.,
Honorary Secretary.

Taunton, November 12th, 1846.

No reply having been received to the second memorial, the following letter was addressed to the authorities of the college:—

To the President and Council of the Royal College of Surgeons of England.

Gentlemen,—We are instructed by the members of the Taunton and Somerset Branch of the Provincial Medical and Surgical Association, to draw your attention to their memorial bearing date November 12th, 1846, and referring to the diploma of a Mr. James Dore Blake, until very lately a retail shopkeeper, and now an homœopathic practitioner in the town of Taunton.

And we are farther directed to enquire whether any, and what answer may be expected to the above memorial.

Signed, FRANCIS HENRY WOODFORDE,
M.D., &c., President,
CHARLES HAYES HIGGINS, F.R.C.S.E.,
Honorary Secretary.

Taunton, December 15th, 1846.

To F. H Woodforde, M.D., and C. H. Higgins, Esq.

Gentlemen,—I have received your letter of the 15th instant, relating to a memorial on the subject of the diploma granted to Mr. James Dore Blake, and inquiring whether any and what answer may be expected to that memorial.

I beg to inform you, that the earliest opportunity was taken of laying that memorial before the Council, who are now engaged in the consideration of the subject, regarding it as one of great importance, and requiring full investigation, which they are determined to follow up with as little delay as possible.

I have the honor to remain,
Gentlemen,
Your very obedient servant,
WILLIAM LAWRENCE.

Royal College of Surgeons,
Lincoln's Inn Fields.

Royal College of Surgeons of England,
29th April, 1847.

Sir,—By direction of the Council of this College, I transmit to you copies of resolutions of the Council, on the 27th instant.

I have the honor to be,
Sir,
Your most obedient servant,
EDMUND BALFOUR, Secretary.

Dr. Woodforde,
President of the Taunton and Somerset Branch of the Provincial Medical and Surgical Association.

At an extraordinary meeting of the Council of the Royal College of Surgeons of England, on Tuesday, the 27th of April, 1847,

Resolved—
That the following resolution of the 19th of April instant be confirmed.

"That it appears to the Council that Mr. James Dore Blake obtained his examination and letters testimonial by false statements and imposition, and

the Council does therefore recall such letters testimonial, and hereby declares the same to be void."

Resolved—

"That Mr. Blake be requested to return the diploma granted to him, he having ceased to be a member of this College."

EDMUND BALFOUR, Secretary.

CORONER'S INQUEST: ABUSE OF THE OFFICE OF CORONER.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

I should feel obliged if you would give the annexed account of an inquest, a place in the *Provincial Medical and Surgical Journal*. The coroner was several times requested to summon the medical attendant, as the jury could not determine what verdict they should return; but he refused doing so, alleging as his reason, "that the magistrates at Pontefract sessions had complained of the enormous amount of money expended in fees to medical witnesses."

Mr. John Barber, aged 73, cut his throat, at half past three o'clock, on the morning of the 25th March last. He went to bed the previous night apparently in his usual state of health; his housekeeper had noticed nothing unusual in his manner. She was awoke early in the morning by the noise of his falling upon the hearth; he had got out of bed, and cut his throat with a razor, whilst sitting in a chair, the chamber-pot, into which he had bled, containing, I should say, about four pints of blood. She aroused the neighbours; I was sent for, and immediately attended. There was very little hæmorrhage after my arrival. I dressed the wound, and with the administration of stimuli and proper nourishment, he rallied for a few days, but soon again fell into a state of collapse, which terminated fatally on the 8th of April. He thus survived the deed rather more than a fortnight.

The coroner, Mr. Wood, of York, was apprised of the circumstance, and an inquest was held on Saturday, the 10th of April, before Mr. Robinson, the deputy coroner. I attended, expecting that my evidence would have been not only necessary, but essential, in enabling the jury to arrive at some conclusion as to the state of mind in which the deceased was prior to, and at the time he committed, the act; but judge my surprise, when the coroner announced to me, even before a single witness was examined, that he could not grant me a summons, for the reason before-mentioned. It was very evident, to all the jury, as well as to myself, that the coroner had come determined not to allow the evidence of a medical witness; for although the jury several times expressed a wish that the surgeon who had attended the deceased should be examined, he remarked they would be compelled to do without him. He said they might ask him any question, but he could not allow him a fee; and as I did not feel disposed to give my professional attendance gratuitously in such a case, I left the room.

The only witnesses examined were his housekeeper and two of the neighbours. The jury were for some time divided in opinion, as to what verdict they should return; some maintaining there was no evidence of a deranged state of mind previously to his committing the deed, and others taking a more lenient and charitable view of the case, deeming the fact of a man committing suicide a sufficient proof of his insanity. Again medical testimony was solicited by the jury, and again refused by the coroner; when a verdict was at last extorted from them of "temporary insanity." I say *extorted*, for I am given to understand that many of them very ungraciously acceded to it, and have expressed themselves as being much dissatisfied with the conduct of the coroner.

The question naturally arises, what is the duty of the coroner? So far as I can learn, it extends to an examination of the circumstances connected with any case of sudden death, or death from violence; and he is to make this inquiry with the aid of a jury, summoned by him for the purpose. This jury are sworn "diligently to inquire, and true presentment make," how and in what manner the deceased came to his death; and what is more natural than, that a jury, wishing to discharge their important duties conscientiously, should wish to have all the assistance they can obtain, by the examination of such witnesses as they may deem essential to a full elucidation of all the facts bearing upon the case.

The principal points to be determined in this instance were—1st, was the wound inflicted by himself or some other person? 2ndly, if inflicted by himself, what was the state of mind in which he was at the time, and the previous state of health in which he had been? and lastly, did death ensue from the effects of the wound, or did the loss of blood tend to aggravate any disease previously existing? and all these important questions were determined without the evidence of a medical witness.

If such be the mode in which inquests are to be conducted, the sooner the farce is given up the better. Such proceedings, instead of rendering the coroner's court, as it ought to be, one of solemn inquiry and investigation, only tend to make their assembly a matter of form, and their verdict a nullity.

I am, Sir,

Your obedient servant,

H. STEAD, Surgeon,

Harrogate, April 15, 1847.

ON PROHYLACTIC REMEDIES.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

During the prevalence of typhus induced by the distress at present existing amongst the poor, it becomes an important question, whether, by any means other than the ordinary precautions, we can lessen liability to contagion? The martyrdom of members of our own and of the clerical profession in Ireland, and the extreme mortality amongst relieving officers in some parts of this country—Liverpool for example—invest the question with more than usual interest. With

respect to contagious fever, I think we may assume that the generality are now humoral pathologists. Can we so alter the condition of the blood artificially and safely as to diminish its proneness to take on the fever change? Animal poisons,—the only admissible one being vaccine virus,—alkalies, acids, quinine, steel, and mercury, are the principal and best-known remedies which modify the state of the blood for the time being.

On the employment of these for the purposes referred to, I have facts only with respect to iron and mercury. They are insufficient also to establish anything conclusive concerning the febrifuge powers of these, but they may prove suggestive to persons whose opportunities exceed my own. From December last to the present time, fever of an unusually falal type has occurred under my notice. Instances of direct contagion have been numerous. It has happened that patients taking steel, and others under the constitutional influence of mercury, have in no instance been affected. Since observing this, steel has been given to some with the intention of testing the view entertained. So far nothing has occurred to decide the question in the negative.

I attach little importance to the facts, they are too few to be deemed more than coincidences; but this cursory note may possibly serve to direct attention to a very grave and interesting subject.

I am, Sir,

Your obedient servant,

C. RADCLYFFE HALL, M.D.

Holmes Chapel, Cheshire.

April 30th, 1847.

INHALATION OF ÆTHER IN TRAUMATIC TETANUS: RECOVERY.

[We quote the following case as reported in the *Derby Mercury*, by Mr. C. A. Hawkesworth, Surgeon, Burton-on-Trent. It is to be regretted that Mr. Hawkesworth did not select some medical periodical as the medium of recording a case, which he states to be "the first of the kind within his knowledge."]

Charles White, about 12 years of age, resident in Stapenhill, near Burton-on-Trent, whilst in the act of chopping wood, struck the back part of his head with the hook he was using, and inflicted a very slight wound upon the scalp. For some days nothing occurred to attract notice, when, suddenly, symptoms of lock-jaw came on, with that peculiar and painful expression of the countenance so characteristic of this complaint; as also with rigid spasms of the muscles of the back and legs; to such a degree that the poor fellow might be truly said to rest upon the back of his head and heels. The usual remedies were tried without effect, until at last I determined upon giving the sulphuric æther a trial. I did so under the able guidance of my friend Mr. Murphy, dentist, Derby, whose well known skill and experience in the exhibition of the remedy render him fully qualified to use it, and in the presence of two friends who were kind enough to lend their assistance.

The narcotic effect was soon induced; in a few minutes the jaw fell, and the whole body assumed a relaxed and passive condition, so that the limbs could be moved about with the greatest ease. Now arose a moment of anxiety. As the boy recovers from the effects of the æther, and with returned sensibility, will the spasm and rigidity of muscles return?

For some time he remained quiet, and talked freely to those around him, and drank a little water. Gradually however, in the course of an hour, the spasm and rigidity returned; but certainly not so violently as before. Recourse was had a second time to the æther with good effect, and during every successive application, the patient became more relieved.

The boy is now well, and I think right to state, that, after the ffrst trial of the æther, his medicine consisted merely of an occasional aperient, which was not so much required as before the æther was used.

INHALATION OF ÆTHER IN SPASMODIC ASTHMA.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

As I have not yet heard of æther being used in the treatment of asthma, I beg to state that I have used it in one case with the most perfect and instant success.

I am, Sir,

Your obedient servant,

W. CANTRELL.

Wirksworth, May 7, 1847.

THE REGISTRATION BILL.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

I cannot but express my astonishment and regret on reading the resolutions published in the public papers by the *Council of the National Institute of Medicine*, against the provisions of *Mr. Wakley's Medical Registration Bill*; and for the following reasons:—

1st. The National Institute has invited every legally-qualified medical practitioner, however humble his qualification may be, to join that National Association, with the guarantee of being admitted to the full privileges of that class of practitioners, whenever they obtain their expected Charter.

2nd. By such a procedure, they have, nominally, given *a legal guarantee to practise*, to those practitioners who *do not possess* the License of the Apothecaries' Company.

3rd. On the face of their former proceedings, this *apparent generosity* to their pseudo-legalized brethren was hailed as an omen of that *good feeling* in the profession which it has *so long needed*; and in that way has increased their numbers and influence.

4th. The Council now come forward and say Mr. Wakley's Bill "*would permit persons possessing a single qualification, to practise the three branches of the profession*" notwithstanding they have *already registered such persons in their list.*

5th. The Council intimate that Mr. Wakley's Bill "*would give increased facilities for practising medicine to*

the chemists and druggists," when on the face of the Bill every possible means has been taken to *prevent* such *unjust* and *illegal interference.*

6th. As the Council of the National Institute know, as well as I do, that the provisions in Mr. Wakley's Bill are just what the profession have a wish and a right to require and demand—*i. e., a legal recognition to practise according to the value of their degrees obtained by examination after regular study;* and "that the *mere* certificate of the Registrar would *not* constitute the only title to practise," and a ready mode of securing those legal privileges they have obtained; preventing the lives of Her Majesty's subjects being tampered with by a host of ignorant quacks, they (the Council of the Institute,) cannot any longer expect the support of those medical practitioners who think rightly on the subject.

Your obedient servant,

E. J. SHEARMAN, M.D.

Rotherham, 11th May, 1847.

Medical Intelligence.

DEPUTATIONS TO SIR GEORGE GREY.

A Deputation from the Council of the National Institute of Medicine, Surgery, and Midwifery, consisting of Mr. Pennington, (President,) Mr. Thomas Martin, of Reigate, and Mr. Clifton, (Vice-Presidents,) Mr. Fuller, Mr. Bird, Mr. Ancell, Mr. Webster, Mr. Barnett, and Mr. Ross, (Secretary,) had an interview on Saturday, the 8th instant, with Sir George Grey, at the Home Office, on the subject of Medical Reform.

Deputations from the Royal College of Physicians, the Royal College of Surgeons, and the Society of Apothecaries, have also been received by the Right Honourable Baronet, at the Home Office.

ROYAL COLLEGE OF CMEMISTRY.

On Tuesday last His Royal Highness Prince Albert, accompanied by many noblemen and gentlemen, visited this College. His Royal Highness, attended by Professor Hoffman, proceeded at once to the laboratory, and inspected this and the other buildings, which are now completed. The visit to the laboratory was made while the students were at work, and the Prince appeared to take great interest in the various chemical processes which were being conducted by the students. The nature of these was fully explained to him by Dr. Hoffman.

His Royal Highness afterwards presided at a meeting of Council, at which a report was read on the completion of the laboratory, &c. The Institution is now stated to be in efficient working order. To the laboratory is attached a library and a theatre, in which chemical demonstrations are given by Dr. Hoffman. Among those present on this occasion were the Marquis of Northampton, Lords Fitzwilliam, Ducie, Ebrington, Newry and Morne, Sir James Clarke, Mr. Blackmore, Mr. B. B. Cabbell, and numerous friends of the Institution.—*Medical Gazette.*

SYDENHAM SOCIETY.

The Society held its fourth anniversary meeting on Saturday, May 1st, Dr. Latham in the chair. The report was read by the Secretary, Dr. Risdon Bennet, and represented the Society as in a flourishing condition. A complete edition of Hippocrates was stated to be in progress, as also a work on medical physiology, and another on medical ethics. A work on ancient medical Bibliography was also in progress. The Treasurer read his report, from which it appeared that there was a balance in hand of £700.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, April 30th, 1847:—J. H. Walker; T. S. Tearne; J. W. Williams; W. H. Cooke; W. Johnson; J. L. Green; R. S. J. Stevens; A. Adney; M. McDonnell; H. J. Barrett.

Gentlemen admitted Members on Friday, May 7th, 1847:—S. Melassez; J. Rushforth; G. Davis; T. Littleton; J. Prowse; D. Hope; H. Hart; R. Capron; G. Milburn.

Gentlemen admitted Members on Friday, May 14th, 1847:—A. N. Holmes; B. Button; F. Gardner; W. J. Anderson; F. C. Webb; J. Milner; W. Copeman; J. Lloyd; J. M. Shain; and W. Ellis.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates on Thursday, April 29th, 1847:—John Robert Humphreys, Shrewsbury; Richard Eliot West, Camelford; George Goforth Wyer, Swayfield, Lincoln; John Sebastian Helmcken; Richard Thomas Smith, London; Thomas Stillman, Steeple Ashton, Wilts; Henry Fisher, Devonshire.

Thursday, May 6th, 1847:—Richard Scott Boley, Bristol; John Rogers, Worcester; Edward John ap Ellis Eyton, Overton, Wales; William Butler, Stoke Newington; Henry Chawner; Robert Martin Craven, Hull; James Graham Nichol, Crook, Durham; George Frederick Burroughs, Sussex.

OBITUARY.

Died, April 23rd, at Oakhills, near Taunton, Henry Sully, M.D., a Member of the Provincial Medical and Surgical Association.

April 28th, aged 71, Robert Masters Kerrison, M.D., F.R.S., of Upper Brook Street, London.

May 3rd, aged 86, Mr. John Read, the inventor of the stomach pump and other apparatus used in medicine.

May 4th, at Tottenham, aged 79, John Ramsbotham, M.D.

May 4th, in Tavistock Row, Covent Garden, aged 52, J. P. Simon, M.D., formerly of Dublin.

May 5th, at Bath, Stewart Crawford, M.D.

BOOKS RECEIVED.

A Bill for the Registration of Qualified Practitioners, and for amending the Law relating to the Practice of Medicine, in Great Britain and Ireland.

Quarterly Return of the Health and Mortality in 117 Districts of England, for the Quarter ending March 31st, 1847.

The Construction and Government of Lunatic Asylums and Hospitals for the Insane. By John

Conolly, M.D., Fellow of the Royal College of Physicians of London, and Physician to the Middlesex Lunatic Asylum at Hanwell. With Plans. London: Churchill. 1847. pp. 188.

Report of the Cumberland Lunatic Asylum, at Dunston Lodge, Gateshead-on-Tyne, for the Year ending January 1, 1847. Edinburgh: Neill. 1847. 8vo., pp. 24.

The Surgeon's Vade Mecum. By Robert Druitt, F.R.C.S. Fourth Edition. London: Renshaw, 1847. pp. 620. Numerous Wood Engravings.

A History of the Discovery of the Application of Nitrous Oxide Gas, Ether, and other Vapours, to Surgical Operations. By Horace Wells, Hartford, U.S. 1847. pp. 25.

A Case of Large Secondary Prostatic Calculus, removed by Perineal Incision, &c. By T. Herbert Barker, M.B., (London), &c. (From the "Transactions of the Provincial Medical and Surgical Association)." Worcester: Deighton. 1847. 8vo. pp. 12.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due, either to the Secretary of the District in which they reside, or to the Treasurer or Secretary of the Association.

ROBERT J. N. STREETEN, Secretary.

ERRATA.

In the No. for April 7th, at page 187, col. 2, line 21, after "Infirmary," read 'a few days.'

For April 21st, Meteorological Journal, Mean of the External Thermometer, 9 a.m. at Romsey, for "25.21" read '35.21.'

METEOROLOGICAL JOURNALS FOR MARCH, 1847.

Kept at Sidmouth, by W. H. Cullen, M.D.; at Honiton, by Mr. Rogers; at Romsey, Hants by Francis Buckell, Esq., Surgeon.

TO CORRESPONDENTS.

Communications have been received from Mr. C. L. Prince; the Birmingham Pathological Society; Mr. W. Allison; Dr. Fife; Dr. Shapter; θ.; Dr. Shearman; the Sheffield Medical Society; Mr. T. Hunt; and Mr. F. Buckell.

It is requested that all letters and communications be sent to Dr. Streeten, Foregate Street, Worcester. Parcels and books for review, may be addressed to the Editor of the Provincial Medical and Surgical Journal, care of Mr. Churchill, Princes Street, Soho.

PROVINCIAL
MEDICAL & SURGICAL JOURNAL.

ON THE RECENT OCCURRENCE OF SCURVY IN EXETER AND THE NEIGHBOURHOOD.

By Thomas Shapter, M.D.,

Physician to the Exeter Dispensary, and to the St. Thomas's Hospital, near Exeter, for Lunatics, &c.

During the last fifty years the occasional appearance of scurvy in prisons and more rarely in the British Navy, has from time to time excited deep attention, but of its occurrence as a disorder of the people little has been heard. It has so happened that very many cases have, within the last three months, come under my observation, and as the accompanying circumstances of the recurrence of this now rare disease are not devoid of interest, some brief record of them may be worthy of a passing notice.

Before I fully appreciated the presence of this disease, my attention had been arrested by the many cases, seeking relief at the City Dispensary, looking pale and sallow, and complaining for the most part of debility, faintness, and pains in the loins and limbs,—a class of symptoms I was at first inclined mainly to attribute to the effects of a long continuance of cold weather, depressing the powers of life, and inducing cold rheumatisms, in persons not enjoying, from pressure of the times, so full a diet as usual. The occurrence, however, of an undoubted case of scurvy of some severity, excited more particular observation, and a visit I was shortly afterwards desired to make to one of the Union Houses of the county, confirmed my opinion as to the true nature of these cases. In some, as will shortly be shown, the characteristic symptoms of scurvy were displayed in an aggravated form, while in others, though accompanied by much weakness and distress, they were only slightly developed.

I shall only briefly allude to the general nature of the symptoms which have marked these cases, dwelling a little more particularly on those accompanying the first ingress of the disease, as the spongy and swollen gum appears to me to have been erroneously estimated as amongst the primary and more obvious manifestations of scurvy. From what has recently passed beneath my observation, I am inclined to say there is a class of well-marked symptoms preceding this peculiar indication of the disease, and that the scurvy gum is rather to be regarded as an evidence of confirmed and advanced disorder.

The first or initiatory stage (and which may continue for a considerable period,) has appeared to me to be characterized by the general and usual indications of debility, with the addition of some few special symptoms;—there is complaint of the ordinary feelings of weakness, of listlessness, and a disinclination to exertion; the patient is nervous; has some little oppression of the breathing, with a feeling of faintness; is chilly; complains of slight superficial pains of the limbs, and more decided uneasiness across the loins; the countenance is pale and sallow; the lips are pale, and the gums are *pale and contracted;* the tongue is clean, moist, and pale; the appetite good; the bowels regular; the urine rather scanty, opaque, and feebly acid; the pulse small, soft, and not quicker than is natural.

In the second stage, the general feeling of debility is more confirmed; the nervousness is of a subdued character, and partakes of despondency; the respiration is slightly accelerated, heaving and somewhat oppressed, and attacks of faintness occasionally supervene; the countenance becomes opaque and dusky, with a dejected expression; the general pains of the body are increased and deeper seated, and the pains of the loins are particularly dwelled upon; there is now the livid, swollen, spongy-looking, but really hard gum, having a tendency to bleed; the breath has a peculiar fœtid smell, not altogether unlike the fœtor of a mercurial taint; petechial spots appear on the legs and arms, and the surface generally is easily bruised; the pulse is small, feeble, and slightly accelerated; occasionally a disposition to feverish attacks is evinced, but these, if judiciously attended to, are easily controlled; in some cases the joints feel stiff, and are really enlarged and painful; nodes form rapidly on the clavicle, sternum, and tibia.

In the third and last stage, (of which I have only seen one case,) the breathing was slow, sighing, and very oppressed; a sanious discharge (very different from the sputum of a pneumonia,) was coughed from the lungs; the gums were swollen and painful, the breath very fœtid, and there was general evidence of the fluids of the body being disorganized, in the

appearance of petechiæ and tendency to bleeding from the gums and mucous surfaces of the vagina and rectum. Some hours previously to the close of life, an inability to articulate the desired words, followed by an overwhelming stupor, induced the conclusion that serous effusion on the membranes of the brain had taken place.

Such have been the general and more striking symptoms which the cases of this disease have presented to my notice, occasionally modified, however, by complications with other and pre-existing disorders. A few cases illustrative of the above shall now be shortly enumerated:—

SCURVY IN THE ADVANCED STAGE; MUCOUS SURFACES EXUDING BLOOD; COMA; DEATH.

CASE I.

A. B———, aged 45, wife of a respectable farmer, naturally of a strong and healthy constitution, cheerful, and of active habits, had for the past six weeks been ailing, but not sufficiently so to induce her to seek for medical aid until about a week previously to my seeing her. The disease had then fully developed itself. There were petechiæ; the gums were spongy, swollen, and exuding blood; the mucous discharges from the vagina and bowels partook of the same character; the pulse was slow, small, and weak; she was desponding and shrinking within herself, and when roused uncertain in her speech; the pains of the surface were general, and somewhat severe, and she was indisposed from this cause, as well as from excessive prostration of strength, to be moved in her bed; in fact everything indicated that the powers of life were subsiding. She died three days afterwards. The diet of this female presented no other alteration from usual custom than the absence of potatoes and other vegetables, having with this exception chiefly consisted of the fare enjoyed by persons in her station of life.

SCURVY WITH PETECHIÆ, AND THE SPONGY GUM.

CASE II.

M. S——, female, aged 36, stout, countenance naturally florid, but now a look of sallowness, has been ailing upwards of a month; feels generally weak; is listless and indisposed to exertion; complains much of pains across the loins; breath fœtid, short; feels faint occasionally; pulse small; petechiæ on both legs; appetite good; tongue clean; bowels regular; gums red and spongy. Has lived chiefly on bread, but of this has had sufficient.

CASE III.

E. R——, female, aged 18, very much out of health; countenance sallow and opaque, with tendency to a yellowish jaundiced tint; general pains of limbs; severe pain across the loins; swelling of the mammary glands, which are very painful; breath short; very much disposed to faintness; pulse small and quick; petechiæ; gums swollen, red, and spongy. Diet chiefly bread.

CASE IV.

T. P——, male, aged 28, plumber, stout, active, and in full work; has been ailing for upwards of two months; countenance pale; complains of general pains, more especially across the loins; general stiffness of the lower limbs, and swelling of the knee; pulse small and quick; left leg much covered with petechiæ; appetite good; tongue clean; bowels regular; gums very much swollen, irregular and spongy, generally red, but along the edges a line of the well-marked lead-tinge. Diet has been ample, consisting of bread, meat, beer, &c., but no potatoes.

SCURVY WITH SPONGY GUMS, BUT UNACCOMPANIED WITH PETECHIÆ.

CASE V.

A. C——, aged 50, nurse; feels weak; complains much of general pains, especially in the knee-joints, one of which is stiff and swollen; breath short; pulse small and quick; gums swollen, red, and encroaching much between the teeth. Diet bread and tea.

CASE VI.

J. M——, female, aged 36; countenance opaque; feels very weak; complains of general pains of the limbs; breath very short; throbbings at the heart; gums spongy, red, and painful. Diet chiefly bread.

CASE VII.

J. B——, female, aged 43; pains of right arm; breathing much oppressed; has fainted three and four times a day lately; gums red, swollen, spongy, and slightly exuding blood. Diet bread and tea.

CASE VIII.

A. M——, female, aged 38, looks ill; countenance opaque; complains of general want of strength; is listless, and incapable of exertion; general swellings and pains of the limbs; breath short; feels very faint on the slightest exertion; pulse weak and small; gums spongy, and exuding blood. Diet has been ample, but devoid of potatoes and vegetables.

CASE IX.

S. B——, female, aged 33; countenance very sallow; complains much of weakness and stiffness of legs; indisposed to exertion; pains in the loins very severe; breath very short, and has fainted away occasionally; pulse quick, and generally disposed to be feverish; gums white at the lower part, at the edges swollen and red. Diet chiefly bread.

CASE X.

S. L., male, aged 32, naturally robust; countenance expressive of debility; complains of his joints being stiff, and there is a swelling of the elbow; the gums are white and contracted below, but red and spongy at their edges. Diet has been ample, of bread, meat, and beer.

CASE XI.

L. C., female, aged 36, generally weak; pain of loins; breath short; has fainted; gnawing pain of stomach; mouth stiff and swollen; gums swollen, red, and tendency to bleed at their edges. Diet chiefly bread.

SCURVY, WITH PALE CONTRACTED GUM, PASSING INTO THE SPONGY SWOLLEN RED GUM.

CASE XII.

E. C., male, aged 17, tailor, countenance pallid and opaque; complains of want of strength and inability to exertion; limbs feel stiff and fail him; has pain of

stomach, and across the loins; breathing difficult; tendency to faint; pulse soft, slow, and weak; has been feverish; gums generally white and contracted, but swollen, spongy, and red at the edges. Diet ample, but deficient in potatoes and vegetables.

CASE XIII.

M. H., female, aged 45, looks ill and weak; countenance opaque; excessive pain across the loins; limbs weak; gums white and contracted, but spongy at the edges. Diet chiefly bread, and deficient in quantity.

CASE XIV.

E. H., female, aged 44, weak; pains in loins; gums white and swollen, subsequently became red and spongy. Diet chiefly bread.

CASE XV.

A. B., female, aged 28, general pains, especially across the loins; jaundiced skin; gums for the most part white and contracted, but red and spongy at the edges. Diet ample, but devoid of vegetables.

Many similar cases might be added to the above, which have been selected as illustrating the general character of the disease in its several stages as now occurring. I shall merely, in continuation, refer to some cases which fell beneath my observation in the Crediton Union Workhouse. In March last, and for some short time previously, much debility and sickness had prevailed amongst the inmates. The sallow countenance and pale anæmic gum could be discovered, both amongst the males and females, while in many of the latter, the gum assumed the decided spongy, swollen, red character. In some this was combined with the pale contracted gum, and in others with the swollen white gum. The worst cases occurred chiefly amongst those of naturally weak constitutions; and as a fact worthy of note it may be mentioned, that the most severely afflicted were children born with a venereal taint. These cases need not be particularly dwelled upon, as they merely presented symptoms similar to those already enumerated; but some brief enquiry into the attendant circumstances may be useful, as from their position these are more certain and defined than in the other cases.

The general construction of the house, size of the rooms, the temperature and ventilation therein maintained seemed to me to be in all respects most unexceptionable. The clothing was warm and sufficient. The printed dietary, which is as follows, is the same as that of every union workhouse in the kingdom.

The weekly amount of food allowed according to the dietary to each—

	Man.	Woman.
Bread	102 oz.	85 oz.
Cooked meat	12 oz.	12 oz.
Soup	3 pints	3 pints.
Broth	4½ pints	4¼ pints.
Cheese	8 oz.	8 oz.
Potatoes, &c.	4½ lbs.	4½ lbs.
Suet or rice pudding	14 oz.	14 oz.

From the failure of the potato crops there has been substituted for this vegetable, during the past year, with the exception of July and August last, when potatoes were used, the same weight of boiled rice, with the occasional use in the soup of fresh vegetables, as cabbage, carrots, parsnips, &c. From this it will be seen that the general diet of the Union has been most ample and excellent, and I can myself testify to the good quality of the several materials used.

We may now proceed to discuss the nature of the disorder affecting these people, and the causes which have tended to produce it. In the first place it may be observed there is every fair ground for concluding, that the cases enumerated in which the gum was pale and contracted, are essentially instances of this disease, but in its earlier and slighter form; they offer the same evidence of general debility, tendency to faintness, oppresson of breathing, pains across the loins,—in fact the same general indications of departure from the normal and healthy state of the blood, differing only in degree from that more-marked deterioration in this fluid, characteristic of the confirmed disease.

We may also conclude that the blanched contracted gum is the forerunner of the swollen, spongy-looking, and eventually bleeding gum; for we have seen in the above cases that the former occurs, on the one hand, in conjunction with the other and more recognized symptoms of scurvy, including petechiæ; while in others it occurs, combined with or passing into the latter. Thus we see the gum pale and contracted, pale and swollen, pale and contracted at the lower part, with a spongy, swollen, red edge; the upper gum pale and swollen, while the lower has been swollen, red, and spongy, the pale gum passing in the course of a few days into the swollen, and then into the red and spongy gum. In fact, the cases offer every variety of example in which the pale contracted gum is combined with the swollen, red, spongy gum; and as the former invariably precedes the latter, and for the most part accompanies the slighter forms of the disease, we are justified in stating that the anæmic gum is one of the symptoms indicative of scurvy, but of the earlier stage of the disease, and which immediately precedes that in which there are morbid deposits taking place, whether these be in the gums, in the joints, in the muscular system, or elsewhere.

There is one other symptom to which attention may be directed,—the pain across the loins. This has been invariably experienced, and has proved most painful and persisting in its nature; it has remained unrelieved, though the gums may have recovered their healthy character, the countenance its wonted appearance and expression, and the constitution its general tone and strength. I am disposed to think this pain is not due to disorder in the urine or kidneys, but to a neuralgia of the lumbar nerves. The frequent occurrence of fixed neuralgic pains in other parts conduces very much to this opinion.

It is unnecessary in the present day to go into any very minute investigations of the remote cause of scurvy; at the same time it may not be altogether useless briefly to review the external relations of the persons who have been submitted to its influence. The more obvious and interesting agents generally to be regarded in an enquiry of this kind, are the conditions of the atmosphere, the occupation of the individual, the nature and amount of his food, &c. &c.

The winter has been unusually severe, and protracted. During the last six months,* the temperature has been lower, with a lower range of atmospheric pressure, and a less amount of rain, than is the usual average of these months, while the winds have blown chiefly from the eastward instead of from the westward.

That cold has some influence in the production of scurvy may be assumed, from its being a disease for the most part of late winter or early spring, and from its frequent occurrence in the colder latitudes of the north of Europe; but that cold is not the cause of the disease may also be inferred, from its not occurring at these periods or in these situations, excepting under certain conditions, and that under these conditions it occurs in warm weather, and more southern latitudes. We therefore conclude that cold is not the cause of scurvy, but that when such cause may be in force, it greatly predisposes to it.

That impure air was not the cause of the disease in these cases is evident, from many of those affected having been persons occupied much in the open air, or living in well ventilated rooms, as in the Union Workhouse, where the usual regard had been had to this particular. Doubtless the living in an impure air would tend to depreciate the general health, and thus render the system more susceptible of the influences of this disorder, but it cannot be esteemed as a cause.

That scurvy is not produced by any peculiar occupation is evident, from its occurrence amongst persons engaged in various trades, as likewise in those following no particular calling. In fact it has been rather shown, more especially in the Crediton Union, by the extreme state of disease in the women and children there, that the want of occupation, and the absence of exercise thereby engendered, much predisposes to its attacks.

We now come to the important question of food:—First as regards amount, there has been, in the course of the above cases, the most satisfactory evidence offered that the cause of this disease can not be referred to a deficiency in this respect, as very many of those affected by it have been well off in means, and certainly those in the Crediton Union Workhouse enjoyed a diet which has been shown to be most ample; we must, therefore, look to kind and quality.

It cannot fail to have been observed that the greater proportion of those afflicted have lived chiefly on fermented bread;* that such bread is not the cause of scurvy, its long and universal use is sufficient evidence, at the same time the occurrence of the disease in those using it so freely, shows it is not, as has been supposed, prophylactic against it. The same may be said of rice, the poor generally not having eaten it, while its use in the union workouse has shown it incapable of preventing its occurrence. That salted provisions are not its cause is also certain, as by far the larger proportion of those affected have not eaten of them. It now remains to speak of the absence from the diet of the usual esculent, the potato. In this respect only has the food of all these people differed from that of other seasons, and it is here worthy of remark, that in the Crediton Union, there intervened between the last use of potatoes and the prevalence of the disorder referred to, a period of about six months, and experience has shown this to be the usual time, a diet devoid of fresh acescent principles takes to produce scurvy.

* It is a remarkable fact that the cases of scurvy which came under Dr. Heberden's observation, at St. George's Hospital, in 1795, had lived chiefly on bread and butter.—"Med. Trans." Vol. IV.

As the recent failures in the potato crops have excited the enunciation of certain political opinions condemnatory of the employment of this esculent, it may not be useless briefly to refer to the conclusions which have been arrived at by able and competent authorities in reference to its anti-scorbutic properties.

Sir Gilbert Blane, in his account of the diseases of the Fleet, in 1781, mentions that the potato, sliced up with vinegar, proved useful in preventing and curing scurvy; similar testimony is subsequently offered by Mr. Dalton. (*Lancet*, Sept. 22, 1842.) Mr. Berncastle, and M. Fontenelle have, however, shown that its usefulness in this respect is not destroyed by cookery as was supposed, the one having employed it boiled in the usual way, the other slightly baked. Dr. Baly, who has given a digest of these and other opinions, (*Med. Gaz.*, Feb. 16, 1842,) adds his own valuable testimony to its being, as ordinarily cooked, "an admirable preservative against scurvy." The facts from which Dr. Baly deduced this conclusion are most striking. As physician to the Milbank Penitentiary, he observed, that scurvy was unknown amongst the convicts whose diet contained a fair allowance of potatoes, (5lbs., together with an onion weekly,) while it was of very frequent occurrence amongst the military offenders, whose diet was almost wanting in this respect, (only ½lb in the week,) and that since these latter have been allowed the larger amount of potatoes the disease has not recurred amongst them. Similar and equally conclusive evidence is deduced by Dr. Baly, from the occurrence of scurvy in other prisons of the kingdom.

We may still proceed one step farther, and show to what peculiar principles the antiscorbutic qualities of the potato are due, and in doing so I shall quote the summary given by Dr. Baly. "A glance at the chemical analysis of the potato, at once explains its antiscorbutic virtue. The various fruits, succulent roots and herbs, which have the property of preventing and curing scurvy, all contain, dissolved in their juices, one or more organic acids,—such as the citric, tartaric, and malic acids. Sometimes these acids exist in the free state, but more generally they are combined with potash and lime, or with both these bases. Now, potatoes have been submitted to most elaborate chemical examination by Einhoff and Vauquelin; and by both these chemists they have been found to contain a vegetable acid in considerable quantity. According to Einhoff this acid is the tartaric, combined with potash and lime. According to Vauquelin it is the citric, partly in combination with those bases and partly in the free state. The farinaceous seeds, as wheat, barley, oats, and rye, which are destitute of antiscorbutic property, contain no organic or vegetable acids."

From all that has been now stated we must come to the conclusion, that the recent occurrence of scurvy in Exeter is due to this one cause—a deficiency of food containing acid principles;* and that the potato has hitherto been the means whereby these acid principles have been supplied. We may farther conclude, that the peculiar symptoms of this disease are not developed until after the system has been deprived of food of this nature for some months; that the persons most liable to be affected by it are those naturally of weak constitutions, or who are submitted to inactive and depressing circumstances; and that protracted cold weather greatly predisposes, on the one hand, by depreciating the powers of the system; and on the other, by checking the growth of fresh vegetables, and rendering such as are raised deficient in proper juices.

From all that has now been stated of this disease,—from its symptoms, its predisposing and remote causes, has any light been thrown on its nature or proximate cause? We see evidently that it primarily consists in a peculiar state of anæmia, and that this anæmic state, unattended by loss of appetite or irregularity in the alvine secretions, is accompanied by a general dusky pallor, weak pulse, breathlessness, and a disposition to syncope—a condition of the system early followed by, and complicated with, low feverishness and tendency to local deposits, causing swollen red gums, stiffness and swelling of the joints, together with petechiæ, hæmorrhage, and nodes, a series of phenomena distinctly indicating the proximate cause of this disease to be a disordered state of the blood, and which disordered state it would appear, from the investigations of Mr. Busk,* mainly consists in the amount of fibrin, albumen, and salts and water, exceeding the proportion of health, while that of the hæmatosine falls below it.

In accordance with the above indications of the nature and origin of this disease, the mode of treatment pursued has mainly been the use of acids, and much benefit has resulted therefrom; otherwise the use of potatoes, if they could be procured good, and other vegetables, has been enjoined, together with oranges, cider, vinegar, pickles, &c., in fact, such treatment as is usually recognized amongst us as adapted for the cure and counteraction of scurvy.

* It must not be understood from this that scurvy is stated to be solely caused by a deficiency of vegetable food. Scurvy is essentially a disease of depraved nutrition, and may be produced by a too restricted and exclusive use of any kind of food. In this paper I am strictly confining myself to the nature and origin of the disease now prevailing.

* Art. "Scurvy," by Dr. George Budd—"Cyclopædia of Practical Medicine."

ON A FEW POINTS CONNECTED WITH THE PATHOLOGY, DIAGNOSIS, AND TREATMENT OF PERICARDITIS.

By E. J. Shearman, M.D., Rotherham.

Pericarditis is a very frequent and a very dangerous disease: it attacks those persons most exposed to changes in temperature and climate, and least likely, from position in life, to be able to take precautions to prevent, or use remedies to cure such a disease. It is consequently of the utmost importance to society that such an affection should, if possible, *admit of easy detection*; and that its *nature* and *treatment* be plain and straightforward to medical practitioners in general.

In Dr. Bartolomé's Essay on this subject, published in this Journal of the 5th of May, he remarks, "The *diagnosis* of pericarditis is not always easy;" it has been mistaken by Corvisart, Andral, and Laennec, for other diseases;—that the "fibrous portion of the pericardium is that first affected;" and he advances a mode of treatment so contrary to that which I have been in the habit of considering as the one most approved of by all the late pathological writers on this disease, that I trust he will allow me to notice his statement, with the laudable motive of searching for truth.

I shall confine my remarks to pericarditis only, although I am perfectly aware that endocarditis, with all the resulting effects of valvular disease, atrophy, dilatation, and hypertrophy, are generally its consequences; but space will not allow these to be named.

The following order may be as well observed:—

1st. The pathological condition of the membrane involved, and its terminations.

2nd. The best mode of determining, by examination during life, the actual condition of the part.

3rd. The most approved method of treatment as described by the best authors of the present day.

I.—The Pathological Condition of the Part.

Although the pericardium is composed of both fibrous and serous textures, yet the same arteries supply both, and it will depend upon the condition of the blood supplying the inflamed capillaries what the exudation corpuscles produce.

Dr. Bartolomé says, "very probably pericarditis generally, if not always, first attacks the fibrous pericardium," then, afterwards, "the most common causes besides rheumatism, are blows, pressure, inflammation propagated along the lungs or pleura, &c." He gives no proof of the fibrous being the membrane first affected, and is "at a loss how to describe the first stage of the disease." But, if pericarditis arises from inflammation propagated along the serous membrane of the pleura and lungs, it is not very likely to affect the fibrous membrane first.

I am not aware of any other author having laid any stress upon the fibrous membrane being immediately implicated. I have had a great many opportunities of examining the parts after death, having during the disease anxiously and narrowly watched its progress; and until I see by dissection that I am wrong, I shall feel inclined to agree in the opinions which I quote below.

The same degrees of congestion, nervous and vascular irritation, determination of blood, obstruction of capillaries from *atonic* enlargement, and adhesion of white corpuscles in the vessels; distension of blood in the arteries *before*, and emptyness of the veins *beyond*, impeded or arrested circulation *at*, and increased circulation *around*, the obstruction; with change in the whole quantity of blood by increase of fibrin and diminution of the secretions, exhaustion and depression either from excessive excitement or the presence of pus or other foreign matters in the blood, must attend this as well as all other inflammations.

If the blood be excessive in red particles, as in very robust and healthy persons, there will be coagulating lymph, serum, and blood exuded; if deficient in red particles, as in anæmic, lymphatic and leucophlegmatic subjects, tubercular deposits will be formed; if fibrin predominate, the serous membrane will be covered with a thicker and more adhesive layer of lymph, and of the most plastic character. But the blood may be so altered in quality, and the quantity of its salts and red particles so much increased, as may produce even osseous deposits. The fibrin may be so low in character as to allow only *aplastic* lymph to be secreted, in which case very slight, if any adhesion, would take place; and pus, curdy matter, yellow tubercle, &c., would be deposited. It might be *euplastic* and become highly organized; or *cacoplastic*, and susceptible of only a very low degree of organization, particularly in the chronic stage, thus giving origin to fibro-cartilage, grey tubercle, &c. It therefore depends on the character of the blood as well as upon the character of the membrane inflamed, what the product of inflammation will be; and this easily accounts for the various statements of many of the old authors,—of bony, bloody, purulent, curdy, fibrinous, and various other effusions having been found in cases of pericarditis.

It is very evident that some of these products of inflammation are much more adhesive in their nature than others, and I have taken the opportunity of naming all, for the purpose of giving the greatest latitude possible to the difficulty this will give us in diagnosis. But it is well known that pericarditis, like rheumatism, is a disease of a highly inflammatory nature, and oftener attacks those whose blood is loaded with red particles and fibrin, than the weak and anæmic; and those who have had the most extensive experience in examining such cases after death, agree in saying that *adhesion of the pericardium* is by far the most frequent result.

The first and immediate effect of pericarditis is

effusion of a small quantity of congulating lymph and serum on both sides of the pericardium; this increases according to the activity of the attack, or the success of remedies. It may go on to such an extent as to bulge out the bag of the pericardium enormously, or it may stop short, and only produce so much mischief, as to impede the smooth motion of the heart in its natural capsule. There may be the other deposits mentioned before, but there *must* be both effusion of lymph and serum.

The general opinion amongst authors, without one exception, I believe, is, that after every case of pericarditis, the lymph unites the pericardium to the substance of the heart, and the cavity is thus either partially or wholly obliterated; and this is considered the most efficient cure which the parts are capable of admitting. For some years I have had the opportunity of watching numerous cases of this disease, in the practice of our late lamented and talented associate, Dr. Favell, as well as in my own; and there are at least two specimens of his in existence, and one of my own, which he added to his collection, where, after the most positive proofs of pericarditis having existed from acute rheumatism, verified by several medical gentlemen and students, the patients quite recovered under the specific influence of mercury, and died afterwards of some other disease. On dissection, the pericardium in each case was found *unadherent throughout*, and the parts which had been inflamed are quite distinct and easily discerned from the rest, being of a much lighter colour, thicker, and raised from the surface of the uninflamed part of the membrane. This is a circumstance deserving notice, for it gives great encouragement to the practitioner to treat the disease very actively, with so good a prospect of perfect success.

II. The best Mode of detecting Pericarditis during Life.

Dr. Bartolomé remarks, "All authors seem to agree, that the most unequivocal sign is the presence of pain over the region of the heart, particularly if aggravated by pressure." He lays great stress upon the quality of the pulse, as a diagnostic symptom, stating in one place that it is "the loose throbbing pulse of acute rheumatism, when the fibrous membrane alone is inflamed, but will vary in proportion as the serous membrane becomes affected;" and in another, that "it is the jerking immediately felt along the arteries, that distinguishes the pericarditic pulse from that produced by merely accelerated circulation." But he afterwards says, "we cannot form our diagnosis from the pulse alone." He mentions the "*bruit de soufflet*," which is *pathognomonic* of inflammation of the *endocardium*, but passes over very slightly the "*craquement de cuir*," and "*bruit de cuir*," and does not notice the "*bruit de frottement*."

The symptoms, as described by Dr. Watson, to whom, simultaneously with Dr. Stokes, we are indebted for the first information of the diagnostic physical signs, are,—a singularity of manner and peculiar expression of countenance, strange aspect of distress in the deportment, palpitation, oppression at the epigastrium, catch in the breathing, dry cough, inability of lying on the left side; pain in the region of the heart, increased by inspiration, pressure between the ribs, or upwards under the diaphragm; stiffness, and pain in the left shoulder, extending into the arm, elbow or wrist; and *delirium*, often *wild* and *furious*, not dependant upon any disease of the encephalon.

All these symptoms put together would not be enough to make us sure that this was pericarditis; for truth, in all its kinds, is most difficult to win, and truth in medicine the most difficult of all. Clinical observation, though never blind, was, until lately, always deaf; but now, with the aid of the ear, when, with even *some* of these symptoms, we find the *attrition murmur*, Dr. Latham says the disease cannot be mistaken for anything but pericarditis.

Before the true *attrition* or *friction-sound* is heard, there is almost always, and generally for some days, a kind of *clanging, harsh, churning, creaking*, or *crumpling* sound heard over some part of the præcordial region, *not* conveyed to the aorta, pulmonary artery, or carotids. This is not constantly present.

In pericarditis there are the fluid products of inflammation as well as the solid: there is serum as well as lymph; and the signs of fluid effused within the pleura and pericardium are the same. The fact of its existence, and the measure of its accumulation within the pericardium, can only be known by the degree and extent to which the præcordial region, and perhaps, some space beyond it, may be *dull to percussion*. Thus, *dulness* sometimes occupies a part, sometimes the whole, of that region; sometimes it reaches beyond, as high as the *second*, and even the *first left rib*; sometimes it extends *beneath the whole length of the sternum*, except about an inch at the top, and even *beneath the cartilage of the ribs on the right side*.

This *dulness to percussion* is a most important sign, and hardly inferior to, or less diagnostic of, the pathological condition to which it points, than the *attrition, friction, or to-and-fro murmur* itself, which is caused by the rubbing of the two layers of membrane on each other, after they are covered with lymph.

But there are two other physical signs of this disease which often but not always attend,—1st, an *undulatory motion*, visible to the eye, *between the cartilages of the second and third, or the third and fourth ribs*, on the *left side*, or in both situations at the same time; 2nd, a vibratory motion, like the purring of a cat, *felt* just over the same places as the undulatory motion is seen. These two last signs sometimes attend disease of the semilunar valves of the aorta and pulmonary artery, and are therefore *not* pathognomonic.

During the life-time of Corvisart and Laennec the physical signs of pericarditis were not discovered, and it is no wonder they speak with so much doubt about it. But since Dr. Watson, of London, and Dr. Stokes, of Dublin, distinctly ascertained that *increased dulness on percussion*, and the peculiar *friction to-and-fro sound*, were pathognomonic of this lesion, no one who has once listened attentively to this sound can ever again mistake it, or misinterpret its meaning.

In all acute cases of pericarditis I believe this *friction-sound* can be heard distinctly if listened for. The harsh churning sounds spoken of before are generally the precursors of this more distinct sign, but they are not always to be heard. The *to-and-fro friction-sound* is always evident, and if watched quite distinct.

In cases where a very large quantity of serum is exuded, the *friction-sound* may only be heard during the first few hours or days of the disease, the fluid having so far separated the pericardium from the heart as to prevent its touching, *at which time the dulness of percussion would be more marked.* But under the influence of proper remedies, this fluid becomes absorbed in a few more days to such a degree, as again to allow the membranes to rub against each other, *and then the friction-sound re-appears.* I believe this very rarely happens, but I have certainly noticed it myself in cases which I have narrowly watched.

The difference of density in the fluid in the pericardium does not alter the *nature* of this *friction-sound*, for it is *conveyed immediately from the outer layer of the pericardium*, and appears to proceed from a surface immediately under the ear. This sound is perfectly distinct from the *systolic bellows-murmur of endocarditis*; but when endocarditis exists at the same time, as is often the case, this bellows-murmur is heard as well, and frequently confuses, for a time, the friction-sound.

I would recommend any one who is sceptical on this point to read Dr. Latham's late work on "Diseases of the Heart," in two volumes, 1846-47. I name this work above all others because Dr. Latham has taken his data from ninety cases of pericarditis, attended by himself in St. Bartholomew's Hospital, all of which were open to the observation of the medical staff of the hospital and students; and he is a physician of such decided talent and probity as to carry conviction to every unprejudiced reader.

But there still may come a difficulty, which I will briefly allude to. In a case of pericarditis which has been apparently cured by treatment, and where most of the pericardium has become adherent; what will be the pathognomonic physical sign, should another attack of inflammation make its appearance? Here auscultation is not to be entirely depended upon. The *impulse* will be *great, tumultuous.* There *may* be some slight friction-sound if a very large part of the pericardium still remain *un-adherent*, but generally there is little or none. If the former attack was cured *without adhesion*, (a circumstance by no means impossible,) then I presume the very same physical signs which have been already described will become again pathognomonic. In most second attacks the endocardium, valves, and cavities become diseased, and during acute inflammation these sounds are often difficult to diagnose, unless the ear be well accustomed to such abnormal sounds.

It may be well to mention a combination of sounds originating in disease of the *semilunar valves* from *endocarditis*, which sometimes simulates this friction-sound of pericarditis, and might mislead an ear unpractised in auscultation. I allude to a *direct* as well as a *regurgitant* murmur existing in the *semilunar valves* of the *aorta* or *pulmonary artery*, and not unfrequently met with in the aorta. The character of this sound is different to the friction-sound, although the peculiarity is difficult to describe. The *length* of *both sounds* in the *pericarditic friction* sound is the *same*, but the *systolic* is *longer* than the *diastolic* sound in that originating in the semilunar valves. A very little education of the ear will be found sufficient to distinguish the difference. The *valvular sound* is also heard *louder* at the *top of the sternum* than at the *apex* of the heart, and is conveyed by the vessels, whereas the *intensity of the friction*-sound is generally in the *opposite direction*, and is *not conveyed* by the vessels. We now come to—

III.—"*The most approved Method of Treatment.*"

Dr. Latham, in 1847, says, "*In foreign practice no mercury is used* from first to last, but all the power of common antiphlogistic remedies is brought to bear upon the disease, and thus its symptoms are mitigated or subdued, yet they return again and again, and are again and again mitigated or subdued, and so the patients are kept alive for a week or ten days, and *then they die*, in the great majority of cases."

M. Bouillaud's treatment of pericarditis is of this antiphlogistic description; he never uses mercury; and in his treatise on it, he says almost every case is found on dissection to have the pericardium adherent. In inflammation of the pericardium the products or exudation of the inflammatory action are deposited in a shut sac. There is not only congestion, great nervous and vascular irritation, and determination of blood, with their usual consequences, but a large quantity of lymph and fibrin are exuded, which, so far as I know of the remedies for inflammation, can only be checked, stopped, or absorbed, *during the time the system is under the specific influence of mercury.*

Bleeding, both general and local, is undoubtedly invaluable, and ought to be carried to such an extent as to cut off the supply of a certain quantity of blood to the part, and decrease the quantity of fibrin in the blood. Purging to a certain extent is necessary, but that will not absorb either the serum or lymph. *Opium is of the greatest benefit*, by soothing the excessive irritability

of the nervous and vascular excitement, and relieving pain; and counter-irritation, particularly blistering, is invaluable, by exciting the action of the absorbents near the seat of the lesion, and in that way relieving the distension of the vessels. But all these remedies combined will not prevent a case of pericarditis making progress to that stage which ends in adhesion and premature death.

I have carefully examined the works of Stokes, C. J. B. Williams, Watson, Elliotson, Hope, Copland, Joy, and Latham, and I find my opinions borne out by all of them. I am convinced that *mercury* has the power of doing *something more* in inflammation of the pericardium than venesection and other antiphlogistic remedies can do; and that, upon this something being done, the life of the patient often depends.

Dr. Taylor, one of the physicians to University College Hospital, who took the highest honors both in the College and University of London, has published in the *Lancet* forty cases of pericarditis, which he has treated in the Hospital under the constant inspection of the pupils. I have read them all, and he has never once omitted to do all in his power to bring the patients under the specific influence of mercury; *where he has failed to do so his patients have died*, but where he has succeeded his patients have generally recovered. These cases are worth reading, being written by one whose knowledge of the disease is more extensive than that of most authors.

In iritis the influence of mercury is quite visible in removing effused lymph, and it thus obviously promotes absorption as well as prevents effusion. In syphilitic ulcers mercury soon removes the callous indolent margin. I have heard an opinion canvassed that mercury destroys the red particles of the blood, and produces a disposition to erythematic inflammation which is incompatible with healthy or plastic. But, if this be true, how can healthy lymph be thrown out, and granulations formed, in such numerous instances under its influence, as we are constantly in the habit of observing? It is more probable that the specific action of mercury *changes the condition of the blood*, and *diminishes the quantity of fibrin and white corpuscles*, as we find mercury most useful when the blood is buffed, and in serous and fibrinous inflammations, where effusions take place to a great extent.

Dr. Latham says, "my experience tells me that whenever the exocardial murmur has ceased early, *salivation* has first taken place." And in the relation of the events of the ninety cases, there were *two* in which he *could not* produce the specific action of mercury. *These two died*, and only one more. In another place, he says, "not in a single instance did the *exocardial murmur cease* to be audible, until *salivation* appeared."

Again he says. "In English practice, mercury is given from first to last, but it is for a time as if it were not given at all, for it produces no sensible effect. Common antiphlogistic remedies, however, are able again and again to mitigate and subdue symptoms; and so, at the end of a week or ten days, the patients are *still alive*, yet they are *ready to die*; but in a great majority of cases they do not die. *Salivation arrives late, and seems to save them.*" !!

Colchicum, tartarized antimony, and aconite, ought to be mentioned as remedies, which occasionally, very much allay the excessive action of the nervous and vascular system. They require caution and judgment in administration, perhaps more so than those before mentioned.

In my own practice I have been in the habit of treating these cases by general bleeding to a certain extent, followed by cupping, leeches, and blisters; but I have placed my chief dependance upon well regulated doses of calomel and opium, and frequent frictions with strong mercurial ointment, until ptyalism is produced.

It would have been easy for me to give numerous other quotations to prove the necessity of putting pericarditic patients under the specific influence of mercury as *quickly as possible*, but space will not allow. I trust, however, that I have not uselessly intruded on this Journal, and refer, in conclusion, to the words of the illustrious Sydenham:—"Ars medendi (si quid ego judico,) in eo potissimum cardine vertitur, ut certa aliqua et consummata undique ac fixa Methodus Medendi in publica commoda tradatur, eam intelligo quae, satis magno experimentorum numero corroborata suffultaque, huic vel illi morbo devincendo suppar invenitur." Sydenhami Opera, Praef. Ed. Tert., 16.

Rotherham, 8th May, 1847.

CASES AND NOTES FROM HOSPITAL AND PRIVATE PRACTICE.

By C. M. Durrant, M.D.,
Physician to the East Suffolk and Ipswich Hospital.

(*Continued from page* 122.)

Case XIX.

HÆMATURIA; ASCITES, AND GENERAL ANASARCA.

An inkeeper, aged 45, of leucophlegmatic habit, requested me to visit him on the 4th of October, 1845. His medical attendant, whom I met in consultation, stated that his habits had been very irregular from excess in drinking; that he had for some years exhibited more or less of the hæmorrhagic diathesis, as evidenced by bleeding from the nose and gums; and that the commencement of his present attack was hæmaturia, followed by general dropsy. He had been out of health for a lengthened period, but the present severe symptoms had existed only for about a week. I found him in bed, his head and shoulders elevated by pillows, and breathing with difficulty; countenance

sallow; conjunctivæ injected and bilious; a scattered eruption of acne rosacea upon the nose, cheeks, and chin; tongue coated with a creamy fur; mouth sore from mercury; no thirst; appetite indifferent; bowels very irregular; evacuations yeasty; complains of a dull aching pain in the lumbar region, not increased by pressure; micturition painful; urine much diminished in quantity, the colour of blood, and containing a large quantity of coagula; abdomen enormously distended, tense, and with very evident fluctuation; its parietes, as also the thighs and legs, anasarcous; scrotum greatly distended, and very painful; pulse nearly natural, and of good strength.

Percussion yielded a tolerably healthy resonance over the entire chest; breath-sound normal, unaccompanied by rhonchus, but of diminished intensity over the lower third of the right lung; no morbid dulness over the præcordial region, and with the exception of a faint blowing murmur accompanying the first sound of the heart, with its maximum over the apex, no abnormal phenomenon was elicited by a stethoscopic examination of this organ.

Ordered—cupping from the loins to twelve ounces; one sixth of a grain of elaterium every three hours, until free purging supervened; saline mixture, with hydrocyanic acid, and spirits of nitrous æther every four hours. To take good mutton-broth or beef-tea, with weak gin and-water as a beverage.

6th. Can now lie horizontally in bed; countenance improved; pulse 72, of tolerable strength; mouth very sore from mercury; has taken half a grain of elaterium in divided doses, from which he has derived great relief, this medicine having procured a discharge of a very large quantity of serum; abdomen less distended, and softer; pain in the back removed by the cupping; scrotum very painful, and not diminished in size; urine still contains coagula.

Repeat the cupping to the loins to twelve ounces; four needles to be inserted into the scrotum; three grains of the iodide of potassium to be added to each dose of the mixture.

8th. Has taken cold, and complains of severe pain in the forehead, which presents an erythematous blush; pulse 80; abdomen diminished in size, and much less tense; scrotum very painful, its integument erythematous; penis greatly distended with serum; urine escaping involuntarily.

Medicine to be continued; to repeat the elaterium; to use a urinal; and to have the scrotum constantly covered with flour.

10th. Erysipelas on the face continues; mouth still very sore; pulse 84; abdomen and legs much diminished; the scrotum still enormously distended, less red, and not painful. One-sixth of a grain of elaterium produced copious watery evacuations; urine still contains much blood, but is free from coagula.

The elaterium to be repeated; face to be covered with flour; to take one grain of gallic acid, with each dose of the mixture; the fluid to be evacuated from the scrotum by means of a small trocar.

13th. Two pints of serum have been drawn off from the scrotum; free purging, with great relief, has again followed the pill; erysipelas greatly disappeared; tongue cleaner; mouth less sore; appetite good; abdomen tympanitic, and now contains but little fluid; scrotum again distended; lower extremities less œdematous; urine still laden with blood; pulse 90, of moderate strength.

Trocar to be re-introduced; repeat the elaterium; to take two grains of gallic acid three times a day. Continue the mixture.

17th. Continues to improve; erysipelas has disappeared from the face; pulse 86; fluctuation in abdomen not perceptible; œdema of scrotum and thighs much diminished; has been freely purged by one-sixth of a grain of elaterium, taken every morning, and by which he expresses himself greatly relieved. Urine contains much blood.

Elaterium to be continued; to take three grains of gallic acid three times a day, with a mixture of sulphate of magnesia and tincture of colchicum.

24th. Marked improvement in every respect; pulse 80, soft and compressible; no œdema of lower extremities; penis and scrotum greatly reduced; integuments of the latter much thickened; appetite good; has continued to derive benefit from the elaterium, taken on alternate mornings; urine increased in quantity, and now contains but little blood; complexion improved; spirits very good.

To take one-sixth of a grain of elaterium every third morning; to continue the gallic acid, with a sixth part of the following mixture three times a day:—R. Liq. Potassæ, dr. j.; Spir. Ammon Arom., dr. iss; Tinct. Colchici, dr. ss.; Decoct. Sarzæ Co., oz. viiss. M. A mutton chop daily, with half a pint of porter.

From this period the recovery of this patient was uninterrupted, and from frequently meeting him, looking in good health, I conclude that he has remained free from a similar attack.

Remarks.—From the unhealthy cachectic condition of the above patient, the general prognosis in the first instance was highly unfavourable, and rendered more so by his intemperate habits of life, his age, and the existence of hæmorrhagic diathesis. The effusion of serum, which obtained to so large an amount, depended upon a highly congested condition of, and consequently obstructed circulation through, the liver and kidneys, and partly perhaps upon a vitiated condition of the circulating fluid itself, as a result of general cachexia.

The effect of the elaterium was most marked; indeed so great was the relief experienced by the full operation of this medicine, that the patient earnestly and repeatedly begged for its repetition. The introduction of a small trocar, for the purpose of relieving the enormously distended scrotum, was also attended with favourable results; indeed, in many instances of serous as well as purulent effusion, it may be questioned whether the relief to the system, and consequently the chance of recovery, would not be materially enhanced by the earlier removal of the fluid by paracentesis. The hæmaturia, (resulting also in part from intense congestion, and in part from cachexia,) although diminished as soon as the balance of the circulation was restored by the mercury, did not subside until a direct

astringent was had recourse to, and for this purpose, as I have almost universally found to be the case, the gallic acid acted most favourably.

Notwithstanding, however, this happy termination, and the immunity from a second attack, hitherto enjoyed by this patient, his life can but be regarded as resting upon a precarious basis. The murmur over the apex of the heart, although but feeble and not constant, was still of a permanent character, and indicated an imperfect condition of the mitral valve. From his addiction to spirit-drinking, unless this habit be relinquished, coupled with the cachectic state of the system, the liver must be regarded as being more or less prone to cirrhosis; or again, the kidneys, from repeated irritation and congestion, to sooner or later assuming the form of granular degeneration.

Case XX.

UTERINE HÆMORRHAGE; DEATH: INSPECTION.

While staying from home, I was summoned in haste to visit Mrs. ———, aged 73. On arriving at the house I was informed that she had been for four years the subject, at intervals, of uterine hæmorrhage, and for which she had been under the care of two or three medical practitioners. On the previous Sunday she had walked to and from church, without increasing the discharge, and her health and strength for some weeks had, it was stated, materially improved.

I found her in bed; face pale; countenance leucophlegmatic; skin cool; in good spirits; pulse 70, of moderate strength; tongue clean; appetite had been tolerably good; bowels regular; hæmorrhage from the uterus copious and clotted, but unattended by pain. Abdominal pressure produces no uneasiness. Has never suffered much pain or sensation of bearing down in the region of the uterus, neither has she been the subject of much vaginal discharge. An examination had once been submitted to, but it was unattended, so far as I could ascertain, by any definite result. The existence of polypus has been suspected. The lady herself attributed her malady, or at all events an aggravation of it, to violent sea sickness, when crossing the Channel. She had used occasionally injection of Matico decoction, and also of the Tinctura Ferri Sesquichloridi.

The most perfect quietude was now enjoyned; the constant application of cold vinegar and water to the pubic region, and the diluted sulphuric acid, with laudanum, every four hours during the night.

On the following morning I met the family medical attendant in consultation. Our patient had passed a good night; the hæmorrhage had diminished, and the same means were directed to be persevered in, with the addition of two grains of gallic acid every four hours.

In the afternoon of the same day, a hurried message was received, stating that "Mrs. ——— was dying." On arriving at the house, we found that profuse hæmorrhage had supervened, the patient was blanched, and pulseless, and breathing with great difficulty; the sounds of the heart very feebly audible, and below sixty in the minute. Brandy and ammonia were immediately administered, which having the effect of producing vomiting, happily restrained the hæmorrhage. Under the liberal exhibition of brandy, the patient gradually rallied; and in the evening of the same day being summoned home, I had not another opportunity of seeing Mrs. ——— again alive.

For the following interesting report, informing me of her death, I am indebted to the kindness of her surgeon, and which, with the account of the *post-mortem* examination, I give nearly in his own words:—

"Our patient, Mrs. ———, sank on Wednesday morning" (a fortnight from the period of my last seeing her) "apparently from exhaustion. She had no return of hæmorrhage after you saw her on the evening of the first, until mid-day on the third, when she had considerable flooding, which did not stop by the usual means. I therefore had recourse to injecting the vagina with the Matico decoction, and plugged it with sponge, retaining it by bandage, and gave a few doses of Secale cornutum. She had no return of hæmorrhage whatever after this.

The treatment now consisted in occasionally giving castor oil as required; quinine, with acid and infusion of roses, and gallic acid in the form of pill with it; the strength supported by animal broth, wine, &c.; the plug changed and lessened in size, using at first astringent injections, and latterly, soothing emollient ones." This somewhat improved condition of the patient continued for about ten days, when (as farther stated in the report of her surgeon) "she suffered from spasmodic pain in the region of the colon and neck of the uterus, attended with spasmodic closing of the lower jaw, but there was no difficulty of swallowing when once the fluids were introduced into the mouth. She occasionally was able to open the jaw sufficiently to allow fluids to pass, but it would quickly become fixed again. This state of things continued for the last thirty-six hours of the poor patient's life. She occasionally slept, but there was not any great mitigation of suffering."

Post-mortem.—"I examined the body about ten hours after death, and found the contents of the chest perfectly healthy; the viscera of the abdomen were also healthy, excepting the colon, which was greatly distended with air, and contained a considerable amount of semi-fluid fæces. Patches of the mucous membrane of this bowel were in a state of congestion; the rectum was quite empty; the uterus externally presented the natural size and appearance; the vaginal surface of the os was congested, and of a violet tint; chronic ulcerations existed within the neck. On cutting through its substance, it presented a softened pale appearance, easily breaking up with the finger, and infiltrated with purulent matter; this condition extended some lines within the neck. The body and fundus of the uterus were quite healthy. The vagina was covered with a muco-purulent secretion."

"I am at a loss" adds this gentleman, "to assign any other cause for death but exhaustion;" and to this condition, engendered by the long continued and profuse hæmorrhages, must the immediate cause of dissolution unquestionably be attributed—"death by anæmia,"—the circumstances attending the latter period of the

patient's existence, the syncope, the cold perspirations, the præcordial anxiety, the slow feeble pulse, and the convulsive closing of the jaw, all indeed indicating an insufficient supply of blood to the heart. While ulcerative induration of the cervix uteri is of very frequent occurrence, ulceration, with ramollissement of its texture, is, as far as I have witnessed, or have been able to ascertain, a rare circumstance, more particularly at the advanced age to which the patient in the present instance had attained. This lesion is slightly alluded to by Drs. Burns and Lever, and more fully described by MM. Duparcque and Columbat de l'Isère, in their respective treatises upon Uterine Disease. The description of the affection given by the latter author, under the designation of "Engorgement congestif avec Hêmorrhagie," is so lucid, that I cannot forbear making a few somewhat lengthy extracts from his work, or rather from the translation by Dr. Meigs.

"This species of engorgement, which may occupy the whole, or only the neck, of the uterus, develops itself in the same manner as the preceding, ('Engorgement sanguin de la Matrice sans Hêmorrhagie;') it is likewise produced by the same causes,—that is to say, by a fluxionary movement, which, in this case, is excessive, and in particular, more prolonged; and which, however, is always accompanied by an abundant and continued hæmorrhage. This sanguine discharge from the vulva, the colour, quantity, and consistence of which are variable, is the most constant symptom of the engorgement which occupies our attention. If we explore the parts by means both of the touch and speculum, we find the neck tumefied, softened, and of a more or less deep red colour. The mouth of the uterus, which is enlarged in proportion to the engorgement, as well as the whole surface of the tumour, is the seat of a sanguine exudation, which, though often considerable and permanent, does not at all diminish the congestion. The os tincæ, covered with clotted blood, appears smooth to view, but somewhat uneven to the touch; by gentle pressure, we perceive a slight sensation of crepitation, and cause an oozing of black blood, which escapes as from a sponge. When the disease has reached its last stage, the skin assumes a yellowish straw tint, as in ordinary cancerous affections; the eyes seem dull; and if some women are observed to retain a certain degree of *embonpoint*, it is because the surface of their bodies has become the seat of a general bloating, which conceals the wasting of their muscles. On examination per vaginam, the neck of the uterus is found to be macerated, and transformed into a sort of ulcer, presenting a layer, which is softened and putrid, surrounded by a hard and, as it were, scirrhous tissue. Hæmorrhagic engorgement which has reached this stage is extremely serious, and there is no hope of seeing tissues, so profoundly changed, return to their normal condition. In general, the danger of the disease is in proportion to the violence and duration of the uterine hæmorrhages."

At the commencement of the above case, when hæmorrhage first occurred, or perhaps before this symptom obtained, the os and cervix uteri were probably simply congested, and this condition becoming aggravated by the violent efforts of retching caused by sea-sickness, merged into a state of intense engorgement or subacute inflammation, which in its turn, having continued for a lengthened period unsubdued, gradually advanced to that of ulceration, and finally softening of the surrounding tissue.

The measures adopted were successful in suspending the hæmorrhage, but from the nature of the lesion this result could only be regarded as a temporary alleviation. As in very many instances in which the os and cervix uteri are irreparably diseased, we found upon inquiry that the general symptoms had at no period become prominent by their severity; indeed the only direct symptom indicating the existence of uterine lesion, had been and was the repeatedly recurring hæmorrhage; but this, although contingent only, nevertheless became at once a dangerous and alarming circumstance, and called for immediate attention.

The consideration of cases like the present is highly instructive, inasmuch as they demonstrate the great importance of early examination and early treatment. Tactile exploration and the speculum became absolutely necessary to the satisfactory elucidation of this class of cases, since early treatment can alone avail and prevent those distressing sequelæ, which, if neglected, sooner or later so inevitably follow.

(To be continued.)

REPORT OF CASES OF STRANGULATED HERNIA, WITH OBSERVATIONS.

By Clement Hawkins, Esq.,

Surgeon to the Cheltenham Dispensary, and Female Orphan Asylum, Cheltenham.

(Continued from page 259.)

REMARKS.

In performing the operation in the cases which form the subject of this communication, the old practice of opening the sac was adopted. I have never witnessed an operation for strangulated hernia in which the stricture was divided and the contents of the sac reduced, without exposing its contents. I have repeatedly seen the attempt made by the most skilful anatomists and dexterous surgeons, but it has always failed, and in many instances the patient has been subjected to the inconvenience of a larger hernia than existed before the performance of the operation, by the division of the external abdominal ring.

About twelve years ago I heard one of the most able and accomplished surgeons in England say, that, however desirable it may be to divide the stricture, without opening the sac, it was a proceeding involved in difficulty, and generally inapplicable in practice. This opinion is opposed to the experience of that excellent surgeon, Mr. Aston Key, to whom is due the merit of reviving the operation of Petit. This gentleman attributes much of the success he has met

with in practice to the adoption of this method. In a recent work on abdominal hernia, by Mr. Teale, of Leeds, there is a table of thirty-two cases of strangulated hernia, in which this operation was performed; twenty-seven recovered, and four died; the result of one is not mentioned. Certainly the amount of successful cases is unusually great, especially as three of the cases were of the umbilical form, all of which recovered.

Mr. Poland has related eighteen operations for hernia, in the "Guy's Hospital Reports" for 1843. In thirteen cases the sac was opened,—six recovered, and seven died; in five the sac was not opened,—three recovered, and two died. I think no surgeon reviewing the history of these cases could attribute the recovery or the death to the mode of operating; many of the cases, as too often happens, were admitted into the hospital in an almost hopeless state, much valuable time being expended in fruitless attempts to reduce the hernia, and others perished from obstinately refusing to submit to the knife until it was too late to afford a good prospect of success. Considerable difficulty will always arise in making a comparative estimate of the success of each operation, inasmuch as the duration of the strangulation can seldom be correctly ascertained. In this particular Mr. Teale's table is very imperfect. The pressure of the stricture on the delicate structure of the intestine, together with the rude manipulations to which the bowel is subjected in the employment of the taxis, is far more likely to produce a fatal termination than a clean cut into the peritoneal sac.

The late Mr. Hey, of Leeds, considered this operation very objectionable and never preformed it.

There is one class of cases, however, in which it is desirable to perform this operation,—namely, in large scrotal herniæ. In these cases, when the intestines are exposed and the stricture divided, considerable time is spent in reducing the contents of the sac; the long-continued manipulations often induce fatal inflammation, or the patient rapidly sinks from the combined effects of exhaustion and the shock of the operation. I consider Case IX to have been an instance in point. When the contents of the sac are intestine and omentum, the symptoms are not so urgent, and the danger of an operation is lessened, because the intestine is protected in a great measure from the injurious pressure of the stricture.

Another cause of failure is, that we are often obliged to perform the operation when inflammation has already attacked the abdomen. In a very large proportion of such cases death ensues. I consider such cases analogous to those in which the trephine is applied to the cranium, when inflammation has set in on the membranes of the brain. We are adding violence to parts already in a state of excitement, the operation fails to give relief, the bowels remain constipated, the sickness continues, especially if the inflammatory action has extended to the upper part of the abdomen, remedies are useless, and an agonizing death puts an end to the patient's sufferings. Case VII is an example.

I am convinced that all treatment prior to the operation for hernia might be dispensed with advantageously in a large proportion of cases occurring in hospital-practice; I have often seen much valuable time expended in preparing baths, &c. The urgency of symptoms must be our guide in each case.

Mr. Pott's opinion was, that the operation, when performed in a proper manner and in due time, does not prove the cause of death oftener than perhaps once in fifty times. And Mr. Hey observes, it would undoubtedly preserve the lives of many to perform the operation almost as soon as the disease commences. In young and robust subjects I have more confidence in a full venesection, and the application of ice, than in the use of hot baths. Mr. Pott, Mr. B. Bell, and Mr. Lawrence, are advocates for the use of the lancet; Mr. Willmer and Mr. Allanson, not only condemn the practice, but even attribute the fatal result, if an operation should be required, to the use of this remedy. Prevention is better than cure; and I fully believe that when inflammation has once attacked the peritoneum in a case of strangulated hernia, death is almost a necessary consequence, however skilfully the operation be performed. The indiscriminate use of any remedy in surgery, however useful, is sure to bring such remedy into disuse and disrepute. Mr Allanson tells us "that bleeding, 'ad deliquium,' had been the constant practice in Liverpool, and as soon as the deliquium happened the taxis was tried, during that stage, but I never saw it succeed;" and adds, "nor do I think bleeding even of the smallest service in forwarding reduction." Mr. Hey, of Leeds, whose practical observations on this subject have been seldom equalled, certainly never surpassed, after quoting the above-mentioned passage, says, "Amidst the contrariety of opinions what path must the young practitioner pursue? I entertain a favorable idea of all these authors, yet it is impossible that I should think them all right in these discordant sentiments. If I may be allowed to judge from my own experience, I must conclude this matter has been carried to an extreme on both sides." He relates two cases in which bleeding was followed by a speedy reduction of the hernia. On the whole, Mr. Hey's experience leads him to concur so far with Mr. Willmer and Mr. Allanson, as to declare, that bleeding has generally failed to procure a reduction of the strangulated intestine, but he does not agree with the former gentleman, in thinking that it generally renders the subsequent operation more dangerous. During my attendance at St. Bartholomew's Hospital, I saw cases of strangulated

hernia, in young and robust subjects, in which bleeding from the arm was practised previous to an operation being done, and the patient recovered without a bad symptom; perhaps they might have recovered equally well if the venesection had not been practised; nevertheless, I attribute the recovery, in a great measure, to the plan of treatment adopted. In Cases I, II, and VIII, it was practised with apparent advantage.

The treatment after the operation in the present age differs materially from that used in former times. I here remark that the cases first related were subjected to a different plan of treatment to that pursued in the subsequent ones. Aperients were given in a few hours after the operation with a view to procure evacuations from the bowels, but seldom succeeded, and it is very questionable whether they were even beneficial. Surely it is more common-sense practice to allow the system time to recover from the combined effects of a distressing disease, and a painful operation, and to give time for the re-establishment of the circulation in the intestine, than to irritate an already irritable and perhaps inflamed intestine, by the exhibition of aperient medicines, which can scarcely fail to excite vomiting and nausea. The opportunities afforded me of witnessing the effects of the one plan as compared with the other, are such as to impress my mind with the superiority of the soothing and sedative method. Purgative medicines and enemata are seldom required during the first thirty-six or forty-eight hours after the performance of an operation; as a general rule the less we do the better.

It would be far more to the advantage and the well-doing of our patients, if we were, in this as well as in other diseases, content to look on and watch them with a jealous eye, and imitate and assist the efforts which nature makes for the reparation of disease, than as too often happens, frustrate her operations by injudicious and meddling interference. The treatment generally most appropriate is to give a full dose of calomel and opium, and repeat it according to circumstances, and if the bowels do not act spontaneously within forty-eight hours after the performance of the operation, if the stomach will bear it, to give a dose of castor oil in a suitable vehicle. If this does not operate in the course of twelve hours, a common enema seldom fails to produce the desired effect, provided no inflammatory action exists in the abdominal cavity. Under such circumstances to persevere in the use of purgatives would be useless, our energies should be directed towards reducing such inflammation. Venesection to any extent is seldom required, and is not well borne after this or any other operation. Leeching the abdomen, freely followed by efficient fomentations, will answer better than the abstraction of blood from the arm. In a great proportion of cases calomel and opium are indispensable.

In Cases VIII and XIV it will be observed that the descent of the testes was incomplete. When called on to operate under such circumstances, it becomes a matter for consideration what course ought to be adopted in regard to the removal of the testicle. In Case VIII, the organ was partly within and partly without the external abdominal ring; and in Case XIV, it was completely within the inguinal canal; in both the pressure of a truss could not be borne, consequently the patients were exposed to the dangers of the hernia becoming again strangulated. Although this form of rupture has been noticed by Pott, Cloquet, and Lawrence, and more recently by Mr. Teale, I am not aware that any of these able surgeons have pointed out the line of practice which ought to be adopted when the operation is requisite. I conclude none of them could recommend the extirpation of the gland. In Case XIV, although neither testis was in the scrotum, the man informed me he was the reputed father of children.

Case X was a very interesting and embarrassing one; the symptoms were not such as are usually observed in cases of strangulated hernia. This case, with the succeeding one, will more properly come under the head of obstructed irreducible hernia; in both the contents of the sac were omentum and colon, and the symptoms resembled those of ileus, and were probably produced by the irritation and inflammation of the contents of the sac, for in neither instance did the symptoms undergo any alleviation after the performance of the operation. In fact the gut was not much constricted; nevertheless, if either had died without any operative proceeding being attempted, I should not have acquitted the surgeons of blame. Whether the exhibition of the pure mercury was really useful I am unable to determine; certainly the effect which followed was truly marvellous, and the bowels were immediately relieved.

While I was preparing this paper for publication, Case XIII presented itself, and the subject of the operation was the oldest patient I ever saw submitted to the knife; it turned out perfectly successful, and the time occupied for the healing of the wound was unusually short.

CASE OF LARYNGISMUS STRIDULUS; INHALATION OF ÆTHER: RECOVERY.

By W. E. Image, Esq., F.R.C.S., Surgeon to the Suffolk Hospital.

Master J——, aged one year, a very fine healthy child, but of full habit and teething, had suffered for several days with repeated attacks of crowing inspiration. On my first visit I found him apparently perfectly well; before I left the house, however, he had a very severe attack. The paroxysms were produced by the slightest mental irritation, and were sometimes so severe that he appeared quite exhausted and in a dying state for a considerable time after the cessation

of the paroxysm. The severity of the attacks daily increased. The crowing breathing was now succeeded by a state almost approaching to asphyxia. The gums were well and repeatedly lanced; the bowels well relieved by purgative medicines; leeches and blister to the nape of the neck, mustard to the legs, hot baths, and cold water to the head at the same time, with other remedies, were used, but without advantage. The attacks increased in frequency and severity. At length he had so severe a paroxysm that he remained two minutes and a half quite unable to breathe. His lips and face were purple; pupils dilated. The body became covered with cold perspiration, and he appeared to be dying. His recovery from this frightful attack was very prolonged. His intellect was not restored till the following day. It was now agreed to apply æther to the nose and mouth on the slightest approach of spasm. Two days after this attack he began to crow as before, and every appearance of a severe attack presented itself. Æther, poured on sponge, was instantly applied to the nose and mouth. The spasms increased for a few seconds, and then perfectly subsided, and the child was well again. For four days the spasms recurred, but were instantly overcome by the æther-vapour, and from that period the child has remained free from an attack, and is perfectly well.

I will not offer any remarks on the foregoing facts, but merely state my conviction, that the æther was greatly influential in preventing a recurrence of the dreadful paroxysms which had so nearly deprived my little patient of life.

Bury St. Edmunds, May 22, 1847.

Hospital Reports.

QUEEN'S HOSPITAL, BIRMINGHAM.

CLINICAL REPORTS OF SURGICAL CASES UNDER THE TREATMENT OF WILLIAM SANDS COX, ESQ.

By Peter Hinckes Bird, one of the Resident Medical Officers.

(*Continued from page* 237.)

Case XXIX.

CARBUNCLE.

Mary Ann Moss, aged 42, housewife, married, admitted August 11th, 1846, into the Queen's Hospital, under the care of Mr. Sands Cox. She states that about three weeks ago she first perceived a circumscribed, livid, red swelling on the back, she opened it with a needle, but no matter came out; a hard immoveable scab formed over it; it gradually increased in size, and caused her much pain; pain described as gnawing, pulling, "as if the flesh were torn from her;" when it had attained the size of her fist, which was about a week since, it broke into a number of small holes, which discharged a large quantity of whitish thin matter, the pain being considerably relieved. Her health has been very indifferent lately; she has been in a weak condition for some time; has had ten children, four of whom are living; had difficult labours with them all, especially with the last; she lost a considerable quantity of blood in her last labour; has been much troubled with headache, described as if "something was hammering in her head," accompanied with singing in the ears and palpitations; has frequently "turned faint;" is not subject to cough. Has had poultices applied lately.

Present State.—There is a large ulcer, rather larger than the bottom of a wine-glass, situated in the right lumbar region, about three inches from the spine; it contains a mass of mortified cellular tissue, of a brownish grey colour; the integument round the edges of the ulcer is of a dusky-red colour, and has a peculiar feel, like that of brawn; the ulcer discharges a thin brownish matter, mixed with strings of a yellowish colour; she complains of but little pain in it now; it is present at times as a slight gnawing pain; she has a pale anæmic look; pulse 90, very weak, easily compressible; tongue moist, of a whitish colour; she complains of a nasty bitter taste in the mouth; appetite indifferent; bowels open; sleeps pretty well at night; also complains of beating pain in the head; the urine was of a light colour, and of natural quantity; it was examined for sugar by the usual tests, but not a trace could be discovered.

Ordered to have a large linseed poultice applied three times a day, and the following mixture:—R. Decoct. Cinchon., oz. viij.; Tinct. Cinchon., oz. ss. M. Sum. oz. iss, ter die.

14th. A large mass of mortified cellular tissue was discharged in the poultice yesterday; the ulcer discharges a thin, lightish-brown, not offensive, matter; she feels better; appetite improved. To have extra diet.

16th. The ulcer is quite free from mortified cellular tissue, and presents an uneven deep excavation. Ordered to have it filled up with dry lint, and covered by strips of adhesive plaster, so as to bring the edges of the wound in rather closer apposition.

R. Quinæ Disulph., gr. xij; Acid. Sulph. dil., dr. j; Aquæ puræ, oz. viij. M. Sum., oz. iss, ter die. Continue the extra diet.

18th. Feels stronger; appetite very good; bowels regular; tongue clean; sleeps well. Continue medicine.

21st. Improving; tongue clean; pulse stronger; bowels open; complains of dull pain over the eyebrows. Continue medicine.

24th. Getting stronger; no pain in the head; is not troubled now with palpitations; the wound looks healthy, and is filling up.

September 1st. Doing well; the granulations are rather indolent; health good; feels stronger. To have the ulcer dressed with lint dipped in a solution of sulphate of zinc.

12th. Much smaller since last report, but it has not made much progress towards healing within the last few days. Ordered to be dressed with the Lotio Nigra.

18th. Improving rapidly.

26th. Quite well; health much improved; no palpitations nor headache. Discharged cured.

Anthrax, or common carbuncle, resembles furunculus

in being attended with gangrene of the subcutaneous cellular tissue; it is remarkable for constituting a dark, red, or livid swelling, accompanied by burning heat, pain and stiffness in the part. It most frequently occurs in those parts of the body where the skin is thickest, and abounds most in those processes of cellular tissue which are described by Dupuytren* as extending between its areolæ. Thus the nape of the neck, the back, the spaces over the scapulæ, the sides of the chest, and the nates, are the most frequent situations of anthrax. In this case its seat was in the lumbar region, which is of rather rare occurrence.

According to Dr. Carswell,† the great accumulation of blood, and the still greater and rapid effusion of serosity which takes place in the circumscribed, acute, inflammatory affections, produce a state of extreme induration of the cellular tissue, a greater or less portion of which, being thus as if strangulated, dies from want of nutrition, becomes separated from the living parts, and is expelled in the form of a grey or straw-coloured spongy or pulpy mass, through an opening made in the skin by a similar process, by ulceration, or by a surgical operation. Besides the production of gangrene and disorganization of the subcutaneous cellular tissue, there is sometimes a destruction of even the subjacent muscles and deeper textures.

Carbuncle is mostly seen in persons beyond the middle period of life whose constitutions have been seriously impaired by some cause. In this case the patient was past 40 years of age, and had been enfeebled by the number of children she had given birth to. The carbuncle also was here of tolerable size; but cases have occurred in which it was as broad as a dinner plate.

As this disease most frequently occurs in persons of a bad constitution, a tonic plan of treatment must be pursued; bark, wine, and a nourishing diet, must be given. With regard to the local treatment, it consists in affording a free escape to the sloughs and matter; a crucial incision is to be performed, but in this case an opening sufficiently large existed for the escape of the mortified cellular tissue.

PROVINCIAL
Medical & Surgical Journal.
WEDNESDAY, JUNE 2, 1847.

The Quarterly Return of Health and Mortality lately issued by the Registrar General, contains, as usual, much valuable information connected with the public health. The effect of severe weather is strongly marked, and, together with the high price of provisions, has tended greatly to increase the mortality. "Winter," it is observed in the report, "appears to be the season in which it is most natural for man to die. For many years the number of deaths in England has been highest in the winter, and lowest in the summer, quarter. In the summer quarter of 1846, the reverse was observed; the mortality was greater than it had been in any quarter of the seven preceding years; and in the last winter quarter, ending March 31, 1847, *fifty-six thousand one hundred and five* persons died in the districts which make the returns; a number greater than has been registered in any corresponding quarter, and *six thousand and thirty-five* above the corrected average."

It will be recollected that the winter of 1845-6 was remarkable for its mildness, as well as for the smaller amount of its mortality; and a comparison of the winter quarter (January to March,) of the two seasons, 1846 and 1847, will place the effect of cold on the mortality in a still more striking point of view. We have seen that the excess in the number of deaths in the quarter just ended, above the calculated average is 6.035; the decrease in the corresponding quarter of the year 1846, was 5.359. The difference between the two therefore amounts to 11,394, or upwards of one fifth of the entire mortality of the selected districts. Whatever effect, however, the severity of the weather may have had in producing this large increase in the mortality, the number of deaths cannot but have been greatly augmented by the want of sufficient nourishment for the poorer classes. The high price of provisions must have operated, both directly in a diminution of the supply of food, and indirectly in putting it out of the power of the necessitous to procure sufficient clothing, fuel, and other comforts, necessary to protect them against the inclemencies of the season. This indirect action of the scarcity has perhaps been more immediately felt than the deficient supply of food itself, as the increased mortality appears very generally to have been owing to imflammatory affections of the lungs and bronchial mucous membrane, the effects of cold on the aged, on children, and on weakly persons, &c.

One of the causes of a high mortality dwelt upon at considerable length in the Report, is the great sacrifice of life, and of infant life especially, from the want of sufficient sanatory regulations in the larger towns. The injurious effect of an impure atmosphere on the health of the metropolis is especially dwelt upon, and the distribution of this atmosphere, "not a gas, but a sort of atmosphere of organic particles, undergoing incessant transformation; perhaps like malaria, not odorous, although evolved at the same time as putrid smells; suspended like dust, an aroma, vesicular water in the air, but invisible," hanging like a "disease-mist," in various degress of density over different

parts of the vast city and its extended suburbs, is forcibly marked out. "This disease-mist, arising from the breath of two millions of people, from open sewers and cess-pools, graves and slaughter houses, is continually kept up and undergoing changes; in one season it is pervaded by cholera, in another by influenza; at one time it bears small-pox, measles, scarlatina, and hooping-cough among young children; at another it carries fever on its wings. Like an angel of death it has thus hovered for centuries over London." And though this disease-mist is not, perhaps, to be altogether "driven away by Legislation," as affirmed in the sanguine language of the Report,—its density, its manifold noxious impregnations, may undoubtedly be lessened, and its health-destroying influences circumscribed. "The poisonous vapour may yet [in part at least,] clear away from London, and from all the other towns of the kingdom;" and "some of the sunshine, pure water, fresh air, and health of the country" become also the portion of the inhabitants of towns.

Before concluding these observations, we would direct attention to the valuable remarks on the weather by Mr. Glaisher, of the Greenwich Observatory, appended to the return. The severe cold experienced in the week ending the 14th of February, and the extreme degree of this on the 12th, in certain districts only, was, according to the Report, confined to a zone, the southern limit of which was in latitude 50° 45, and the northern limit, in latitude 52°. This cold was most severe at Uckfield, the thermometer falling there, according to the observation of Mr. Prince, as low as 1°; at Blackheath, the lowest point of the thermometer on the same day was 6°, at Beckington, in Somersetshire, 5°, and at Romsey, Hants, as appears from Mr. Buckell's report, published in this Journal, it was 6°. It is worthy of remark that the lowest point of the thermometer observed during the month, both at Sidmouth and Honiton, was on the same day of the month, the 12th, though the amount of depression, as recorded by Dr. Cullen and Mr. Rogers, was very different, being in the latter place to 18°, and in the former not lower than 21° 5.

Review.

The Construction and Government of Lunatic Asylums and Hospitals for the Insane. By JOHN CONOLLY, M.D., Fellow of the Royal College of Physicians of London, and Physician to the Middlesex Asylum at Hanwell. London: 1847. 8vo. pp. 183.

This is a small and unpretending volume, but at the same time, one of those rare productions which leaves little of material import unsaid on the subject of which it treats, and contains no redundancies, either of matter or expression. The enlightened views known to be entertained by Dr. Conolly, on the subject of the management of the insane, the deep attention which he has paid to the subject, and the genuine benevolence which his published sentiments, his public acts, and his private intercourse alike evince, render such a treatise as the work before us a work of no ordinary interest. The interest is not confined to the physician, but must be equally participated in by the general philanthropist, the magistrate, and the public at large. Happily it is unnecessary in these days to dwell on the general truth and practicability of those humane principles in the management of the insane, the working of which, the labours of Dr. Conolly have so much contributed to advance; but there are numerous minor points which yet require consideration connected with the best mode of carrying these principles into operation, and on these the present work affords much valuable information and instruction. By those to whom the general and medical treatment of the insane is confided, the opinions of Dr. Conolly cannot but be perused with great interest, and the correctness and applicability of his views will be tested by the results of their own experience. But there are persons whose duty it is no less to investigate the several questions connected with the management of asylums for the reception of insane patients, who have no previous instruction on the subject, neither from practical experience nor education. To county magistrates particularly such information as is here conveyed is of great importance, and we trust that the valuable observations of the author will have extensive circulation among the magistracy of the country, that while all due economy in the appropriation of public funds to the care of the insane is practised, no miserable parsimony may be suffered to cripple the efficiency of a system of general management, which has converted the receptacles for lunatics from gloomy and desolate prisons, into cheerful habitations, into hospitals for the curable, and into places of refuge and homes for those whose mental condition admits not of restoration to health.

The following eloquent passage in which the duties of the Superintendent are briefly summed up, glowes with the purest sentiments of humanity and benevolence, and in every sentiment will be recognized by our readers the impress of the author's mind:—

"None," says Dr. Conolly, "but those who live among the insane can fully know the pleasures which arise from imparting trifling satisfactions to impaired minds; none else can appreciate the reward of seeing reason returning to a mind long deprived of it; none else can fully know the value of diffusing comfort, and all the blessings of orderly life, among those who would either perish without care, or each of whom would, if out of the Asylum, be tormented or a

tormenter. Constant intercourse and constant kindness can alone obtain their entire confidence; and this confidence is the very keystone of all successful management.

"Thus living, and thus occupied, the director will learn to love his people, with all their infirmities, which are their afflictions. The Asylum is his world. The patients are his friends; humble, but not without even delicate consideration for others; wayward, but not malignant, except when cruelty exasperates them; capricious, but not ungrateful; distrustful, but to be won by candour and truth; disturbed and grievously afflicted, but not dead to some of the best and purest affections. He will almost regard his patients as his children; their cares and their joys will become his; and, humanly speaking, his whole heart will be given to them."

Proceedings of Societies.

BIRMINGHAM PATHOLOGICAL SOCIETY.

March 6th, 1847.

Dr. Fletcher in the Chair.

TUBERCULAR DISEASE OF THE PERITONEUM.

Mr. F. Elkington presented to the Society a specimen of tubercular disease of the peritoneal coat of the stomach, and gave the following history of the case:—

Margaret Robins, 65 years of age, a native of Wales, came to England when 16 years of age. Her mother died in a fit at the age of 23. Her father died when she was about four years of age, of an acute disease. Has been married twice; her first husband died eight years after their marriage. In 1813 she was married to her second husband, who died of lupus, in March, 1846. From her account it appears that she had during early life, an attack of pleuritis, and two large abscesses just above the crest of the right ileum, the cicatrices of which are still remaining. Has never had scarlet fever, typhus fever, small pox, &c.

August 1st. 1846. She considers the present complaint to be of about six years' standing, during which period the following symptoms seem to have been gradually increasing in severity:—Violent spasmodic pain in the side (sometimes the right, and at others the left,) on the slightest exertion, or on taking certain articles of food; a sensation of *pain after eating, and sometimes vomiting*; violent palpitation of the heart, constipation, and depression of spirits. *Present* appearance is as follows:—*Countenance* exhibits great anxiety of mind; cheeks depressed; features contracted, with slight hectic flush upon the malar bones.—*Tongue* coated with a deep white fur in the centre, and a brownish one round the margins, *tremulous*.—*Pulse* 100, small and compressible.—*Chest*-sound, healthy; no cough nor pain over the region of the chest; *heart's* action quick but natural.—*Abdomen*: no tumour to be discovered by the hand; complains of violent pain over the whole region of the stomach, increased upon pressure; constipated bowels; scanty high-coloured urine.

Treatment.—I ordered eight leeches to be applied over the region of the stomach, and after their removal a blister, a saline mixture every four hours, with two pills composed of Pil. Hydrarg., Extr. Colocynth., et Hyoscyamus, at *bed-time*. By this treatment the pain over the stomach became much diminished, and by omitting the saline medicines, and giving tonics, (vegetable,) together with the pills, her general health was much improved, and after three weeks from the time of my first visit, she requested me to let her go to Tamworth. This request was complied with, and I lost sight of her until asked to see her in February, 1847, when I found her in a dying state, with suppression of urine, distended abdomen, and vomiting of fœtid matter. She died three days after this, and on the fourth day I performed the *post-mortem* examination.

At the particular request of her friends, the abdomen alone was opened. External appearances:—The whole of the body extremely emaciated; cheeks sunken; abdomen enormously distended. On the left side above the crest of the ilium were two large cicatrices, which had been evidently formed by the healing of abscesses. On opening the abdomen, at least a gallon of fluid was evacuated from between the layers of the omentum. On examination superiorly, the liver appeared of full size, of rather darker colour than natural, overlapping the stomach, which appeared contracted to the size of the closed fist. The gall-bladder was full of bile, which was of a natural colour, and on making a section into the liver it presented the appearance usually seen in what is termed a nutmeg liver. Nothing else remarkable was observed in this organ. The stomach was surrounded and firmly adherent to the gastro-hepatic omentum, which presented a scirrhous appearance, with little spots of tubercular matter of a pinkish colour interspersed in various places. After separating the stomach from its attachments at the pyloric and œsophageal extremities, and removing the omentum as far as was practicable, the most remarkable feature was its extremely contracted size; hardness on its external surface; both anteriorly and posteriorly were large deposits of a pinkish colour, one in particular posteriorly, and nearly the size of a nut, which at this period had quite a calcareous appearance; the internal surface presented the same appearances as in the specimen. The small intestines from the duodenum to the extremity of the ileum, presented quite a dark appearance, which on more minute examination appeared to be owing to deposits similar to that on the coats of the stomach. The colon was empty and had these deposits only in its transverse portion; none were discovered in the rectum. The spleen was in a natural state, without deposits; nor were any discoverable in the pancreas which also assumed its natural appearance. The kidneys were of the usual size, very firm and hard to the touch; on making a transverse incision the pelves appeared dilated, and no distinct line of demarcation could be traced between the cortical and medullary portions, for the former encroached on the latter, and one was blended with the other. The ureters were much dilated, but more at the renal than the cystic extremities. The coats of the bladder were thicker than natural, but no deposits could be traced on them.

similar to those in the other viscera. The uterus was not opened. The peritoneum in the upper part of the abdomen was healthy; the lower or pelvic portion contained the pinkish deposits, easily recognized after being washed in water.

OBTURATOR HERNIA.

Mr. Hill brought before the meeting a sketch of a hernia of the obturator foramen, and gave the following description of the case:—

Ann Mills, aged 72, an unmarried female, of spare habit, was suddenly seized on Friday, 18th of February last, whilst at dinner, with a feeling of depression, which obliged her to lie down. She did not then complain of much pain, but gradually became worse until the following Tuesday, when I was requested to see her. I found her suffering from obstinate constipation, accompanied with vomiting and great depression. She complained also of tenderness in the belly, referred chiefly to the right iliac region. There was no fullness in either groin nor in the left lumbar region. She gradually became worse; she vomited matter acquiring a stercoraceous character, and at last having a black colour. She died on Friday, the 25th.

On examination *post mortem*, we found the small intestines much distended, and on tracing them downwards, the hand was directed to the right obturator foramen, into which a small knuckle of the ileum had passed. The portion strangulated did not comprise the whole calibre of the gut, but the obstruction to the passage of its contents was complete. The intestine above this part was gangrenous, and burst on the slightest pressure. Below the constricted portion the canal was quite empty.

SHEFFIELD MEDICAL SOCIETY.

Sixth Session.—Fourteenth Meeting, April 1, 1847.

The PRESIDENT in the Chair.

SCIRRHOUS UTERUS.

Dr. Branson exhibited a scirrhous uterus which had been sent to the Museum of the Infirmary by Mr. Boddington, of Chesterfield. The patient complained of leucorrhœa two years ago, but last July it was found to be carcinomatous disease. The pain was unusually severe and required most powerful anodynes. She died very much attenuated. On inspection the os uteri was scarcely implicated. The patient was forty years of age and had borne six children.

NECROSIS OF THE ACROMION SCAPULÆ.

Mr. H. Jackson exhibited a portion of necrosed acromion, removed from the shoulder of a man aged 27, by trade a comb-maker, but who had for six years been a sailor. About a year and a half ago he complained of pain in the shoulder, which he took to be rheumatism, and used stimulating liniments with temporary relief. About eight months ago he rubbed it with hot turpentine and mustard, which produced ulceration, and several small portions of bone came away. The ulcers then cicatrized, but about three months ago re-opened, and the bone then became exposed, and finally about an inch was removed.

Dr. Shearman exhibited Dr. Simpson's instruments for the exploration of the uterus.

ÆTHER-INHALATION.

Mr. Law exhibited a portable apparatus for the inhalation of æther, registered by Atlee and Company.

Mr. Michlethwait read from the "Veterinarian" for April, 1847, an account of an experiment with æther vapour on a horse, conducted by Messrs. Henderson and Cherry, which terminated fatally in six minutes. The diaphragm and aorta at its commencement were both ruptured, but the case was of general interest, as bearing upon the subject of æther-inhalation.

CASE OF MANIA.

Mr. Ray detailed the particulars of a case of mania, occurring in a lady, aged about 30. The mania appeared to be the result of anxiety and distress, resulting from the illness and death of an intimate friend, to whom a promise was made of a strict observance of religious duties, and the delusion consisted in the idea that she had broken the promise, and was condemned in consequence, to exposure in a state of nudity, without food, in the open streets. All the functions were healthy. All reasoning was fruitless. But the use of blisters, and tartar emetic both inwardly and externally, produced in five days the desired effect. The case was of interest inasmuch as the mania yielded to the treatment much more rapidly than might have been expected, or than is usual. The patient has since continued perfectly well.

Dr. Shearman read a paper "On Certain Non-malignant Tumours of the Uterus," which he illustrated by microscopic drawings made by Dr. Branson. This paper will appear in another number of the Journal.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DES SCIENCES, PARIS.

March 22nd.

ÆTHER INJECTED INTO THE ARTERIES.

M. Flourens related experiments in which he injected æther into the arteries. He states that it does not produce the phenomena of *ætherization*, and that neither does the injection of æther by the stomach. This he has repeatedly ascertained.

ACTION OF ÆTHEREAL VAPOUR COMPARED WITH THAT OF THE NON-RESPIRABLE GASES.

MM. Preisser and Melays, of Rouen, related experiments to prove that a cessation of the pulmonary changes of the blood is the explanation of æthereal insensibility. They have ascertained—1. That arterial blood always becomes dark under the effects of æther. 2. That this change precedes the insensibility. 3. That after the æthereal inhalation was suspended, the arterial colour of the blood is restored previous to the return of sensibility.

In order to determine whether the mere privation of oxygen is sufficient to produce insensibility, they caused animals to inhale nitrogen, protoxide of nitrogen, &c., and found that in all insensibility was preceded by a dark colour of the arterial blood, and that a return to

its normal colour preceded the return to sensibility. From these data they decide that æther simply asphyxiates.

March 29th.

WOUNDS OF THE STOMACH CONSIDERED IN REFERENCE TO THE OPERATION OF GASTROTOMY.

M. Sedillot presented a memoir in which he not only maintained the curability, but the harmlessness of wounds of the stomach, when made with proper precautions. The operation of opening the stomach, and making a permanent fistula, has been proposed in cases of obstruction of the œsophagus.

The meeting was subsequently occupied by some unimportant communications on æther.

ABSTRACT OF THE PROCEEDINGS OF THE ACADEMIE DE MEDECINE, PARIS.

March 23rd.

INHALATION OF ÆTHER.

M. Blandin occupied the attention of the meeting with a retrospect of the experience connected with æther-inhalation. As many others have done, he considered the effect of æther to be analogous to that of alcohol, and admits with Longet separate steps in the insensibility. In the first, he maintains that there is always a certain amount of excitement. In the second insensibility declares itself in a marked degree; the patient experiences a sensation of weight in the head, giddiness, and noises in the ears. In some, prostration is complete; in others a tetanic spasm is induced. Some shed tears; others exhibit a mental emotion indicated by smiles. At this time the influence of the æther is confined to the cerebral lobes; the patients are still sensible to pain, but on emerging from the æthereal trance they have lost all memory of it. In the third period, that of *ætherization of the protuberance*, of Longet, the scene changes; excitement is succeeded by insensibility, the life of relation is suspended, reflex action is abolished, the pulse is lowered, the blood loses its florid colour. This is the extreme point to which the inhalation can be carried with safety; but the condition may be prolonged by management, or the patient may be allowed to recover himself, in which latter case he passes reversely through the same stages. If, continues M. Blandin, we are to believe the first experimenters with æther, none but pleasurable sensations are excited; but we cannot deny that the contrary is frequently the case. It is certain, however, that the æthereal delusions, are often in correspondence with the ages and circumstances of the patient: the little child dreams of its playthings;—the lascivious woman believes herself in the embraces of her lover, and her motions not unfrequently indicate the sensations of venereal enjoyment;—the religious enthusiast dreams that she is in heaven, &c., &c. Be it as it may, the effect is transient, though not so transient as is supposed. In fact, the fluids and solids are penetrated with the æther, as the breath and urine testify many hours after. In some cases we have known headache persist during the day, and in others we have seen so much cerebral congestion as to require blood-letting.

M. Blandin proposes two questions of paramount importance, viz.:—1. *Can death be produced by the inhalation of æther?* 2. *Is the fatal event far removed from the point of obsolete sensibility.* It is impossible, he says, to doubt that the former question may be answered in the affirmative. The fact is proved by physiological experiments, that if the action of the æther be carried beyond a certain point, the respiratory tract is paralysed and death ensues. In answer to the second question, M. Blandin remarks, that in rabbits, perseverance in inhalation for four or six minutes after complete insensibility, destroys life.

MEDICAL REGISTRATION BILL.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

As an old member of the Provincial Association, may I be permitted to ask you to insert in an early number of the Journal, the following brief observations upon the state of the medical profession, both in relation to its benefits towards the public, as well as to the honour and dignity of the science of medicine and surgery.

I consider the present time one peculiarly adapted for every member of the medical and surgical profession, to offer his conscientious opinions upon the present state of his profession, and that, without the fear or intention of giving offence to any one. I am quite aware that it is a subject that may give umbrage to some parties, however guarded one may be in giving vent to one's feelings. The numerous and conflicting interests and opinions of the profession are such, that it is beset on all sides with great difficulties, but if we all consider the subject as one in which the public are intimately interested, and argue that it is for their benefit, it will in a great measure divest it of any feeling of self-interest.

No one will doubt for a moment, that society must derive a much greater advantage, if the whole of the members of the medical profession are thoroughly well educated. It must therefore be most desirable that none should be allowed to practise but those who are legally, and at the same time practically, well fitted; and what will tend to accomplish such an end but a strict registration, combined with an examination, so that every one who enters the profession, shall be both theoretically and practically educated, of which the public should have some guarantee. The Bill recently introduced into the House of Commons by Mr. Wakley, contains everything that will ultimately accomplish that end. There are certain influential bodies that no doubt will be opposed to such a system; because it will tend to raise the standard of the profession generally, the public will feel more confident in their usual medical attendant, which would interfere very much with the private interests of those immediately connected with the public institutions of this country. But, in a *public* point of view, *private* interests ought not to weigh one atom in the scale. As far as the legislation is concerned, anything and everything that tends

to raise the standard of the profession in this country, would confer a great blessing on the public, and particularly upon the middle and poorer portions, which form at least two-thirds of the whole. Ought not the surgeon who is about to practise in the remote parts of England, Scotland, or Ireland, to be as well informed as he who practises in any of the cities or large towns? The middle and poorer classes have not the means of applying to those who are supposed to be the leading men in the profession; and pray what is to become of them? Are they to be permitted to suffer and die, because the private interests of a few influential persons connected with our public institutions would be interfered with? If every medical man was thoroughly well *qualified* to practise, it would not be a matter of so much importance to the poor, who require medical and surgical attendance under the Poor Law, for then, in all probability, union medical officers would be sufficiently well paid, to do justice to the cases under their care; but as the law now stands, there is too much reason to believe that much suffering, as well as the loss of many valuable lives, is constantly occasioned by the present mode of dealing with union medical officers. It therefore becomes the duty of every medical practitioner to rally round the greatest benefactor both to the public, and to the profession, by petitioning and by explaining to the various members of Parliament, the necessity of supporting the Bill now before the House. It has already been assailed, and every nerve will be exerted by the institutions of this country to oppose its passing into a law;—and for what reason? Simply because such a Bill would go far to equalize the standard of the professsion, and do away with the necessity of having recourse to expensive consultations. It therefore becomes a question as much for the consideration of the public, as of the profession; and I hope that every scientific practitioner will spare neither time nor pains to forward the passing of the Medical Registration and amended Medical Bill.

I am, Sir,

Your most obedient Servant,

GEORGE BOTTOMLEY.

Croydon, May 20, 1847.

TOTAL ABSTINENCE AND MEDICAL TESTIMONY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOUNAL.

SIR,

I beg leave to trouble you with a few observations on a letter by Mr. Edward Humpage, of Bristol, in your last number.

The position which in my former letter I ventured to defend was that of temperance, *versus* abstinence, and I thought I gave *sufficient reasons* for our pausing before we commit ourselves to a professional opinion in favour of extreme views on a subject of great social importance. These reasons are at least conclusive to myself as regards the erroneous character of the views in question. I was far from supposing that my observations on this subject were calculated to excite a single angry feeling. I innocently supposed, that although various distinguished members of the profession have given a qualified opinion in favour of total abstinence, it did not argue any great presumption, or as Mr. Humpage avers, "want of good taste," to dissent from and controvert such opinion. That cause is seldom very good, or its advocates very judicious, which seeks support in the *argumentum ad verecundiam*; whilst, however, I shall not give place to Mr. Humpage in a just reverence for the real masters of medical *art* and *science*, I shall certainly not resign my right of investigating and judging for myself, nor shall I shrink from giving my opinions to the profession and to the public, as I may think desirable.

I have not the least reason for believing, that the opinion of which Mr. Humpage is the vindicator, is really entertained by any considerable number of observing and experienced physicians and surgeons; but, were this even the case, and had a much larger number of the names, *collected* by Mr. Dunlop, been as deservedly eminent as those *selected* by Mr. Humpage, I cannot admit that I am to be adjuged guilty of any disrespect in submitting to the profession those views which appear to me to be correct.

Your correspondent is pleased to characterize my observations as absurd and ludicrous, but, thus regarding them, I can only express my surprise that he has taken the trouble in any way to notice them.

Mr. Humpage asks which of the four statements in the declaration before us I consider so rash and dangerous? To this inquiry I answer, that I regard every one of them as *unproved;* and, so far, consequently, as rash and dangerous. I shall not trouble your readers with my reasons for this opinion, as these may be, to a great extent, gathered from what I have stated in my former letter. I may, however, observe that, before I could append my name to such a document, I should require such modifications in each statement, as would leave the declaration one in favour of temperance, rather than abstinence. I will state the more important of these modifications. In the first statement, the substitution of the word "abuse" for "use;" in the second, the insertion of the word "frequently" before "compatible;" and in the third, that of "generally," before the phrase "with perfect safety." As regards the fourth statement, I will merely observe, that believing as I do, that there are great numbers of persons to whom stimulants of some kind are not merely unobjectionable, but even necessary for health and comfort, I could not accept it in its present form.

There are, on the other hand, many persons, as I freely grant, for whom total abstinence from fermented liquors is, both on physical and moral grounds, desirable. Granting this, however, I must still resist the conclusion that we are called upon, by any consistent standard of morals, to banish wine and other fermented liquors from the *materia dietica*, and to restrict them to the *materia medica*, much less to exclude them, as some enthusiasts in the cause of abstinence desire, from the catalogue even of medicinal agents!

As regards the views of Liebig and Mitscherlich, Mr. Humpage has altogether misrepresented my object, in alluding to them. This object was simply that of shewing, that the prevailing doctrines in vital chemistry

do not justify the conclusion that fermented liquors are necessarily injurious to man; on the contrary, it would appear, that these fluids, like starch, sugar, fat, and the non-azotized ingredients of our food, minister not to the *nutrition* of the body, but to the *development of animal heat, and to the protection of the organism from the action of the atmospheric oxygen*,—objects scarcely second in importance to nutrition itself. Mr. Humpage refers to Liebig's "Familiar Letters on Chemistry," as favorable to his views. A reference to them will, however, shew, that the statements they contain are identical with those in the larger work from which I have quoted.

I shall not follow Mr. Humpage farther in his somewhat angry comments on my letter. Which of us has the greater cause for the disturbance of our equanimity I will leave to you, Mr. Editor, and to your readers to determine. My object has been that of attracting attention to a subject which I regard as important alike to the public and to the profession. I was aware that unworthy means have, in some instances, been resorted to, in order to procure signatures to declarations of this kind; and I thought that a caution on this subject, as regards some members of the profession, might not be altogether without its use. Whether this be the case or not, I must leave your readers to decide; but I must altogether disclaim the imputation of giving oracular cautions to the distinguished men alluded to by Mr. Humpage.

If I have not written in *propriâ personâ* on this subject, it has not been in order to express opinions which I am not ready to avow, on all proper occasions. I had no discoveries to communicate which called for the authentication of a name. I was dealing with old and well-known facts, and I was desirous that my observations, however they may be estimated, might neither lose weight, nor find adventitious support, from personal considerations.

Before concluding this letter, I will take the opportunity of expressing a hope that the members of the profession will render all the assistance in their power to Dr. Bowring, in his legislative attempt to procure the repeal, or at least, the large reduction, of the duties on foreign wines. By such a measure, particularly as regards the wines of France and Germany, the cause of temperance, and of hygiene, (in so many points identical,) cannot but be materially advanced. Another matter, which seems to call for renewed attention, is the exposure of that abominable system of adulterating and mixing wines, which exists on so large a scale in this country. No practitioner of experience can doubt the evils which arise from the extensive admixture of brandy with the port and sherry ordinarily consumed in this country, but the demand for which would greatly diminish, were the duties on other wines reduced to a more reasonable rate.

I am, Sir,

Yours respectfully,

O

[This letter was intended to be inserted in the previous number, but was unavoidably delayed.]

MEDICAL TESTIMONY IN FAVOUR OF "TOTAL ABSTINENCE."

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

It is not my intention to embark in the controversy now subsisting betwixt Mr. Humpage and your accomplished correspondent θ, nor is it my purpose to discuss, except collaterally, the merits of teetotalism—a system which I know many well-meaning and sincere persons devoutly believe to be the greatest moral and social reformation of modern times; whilst the rest of the world look upon it as an egregious piece of folly, or, at best, as an ephemeral bubble, blown up into a popular "movement" by the restless egotism of this busy and self-relying age. My chief object in now addressing you is, to analyse the four propositions put forth by the advocates of total abstinence, and to consider whether the members of our profession are justified in signing them, consistently with physiological truth, and with a due regard to their own reputation, as men of science, and men of sense.

Permit me to copy, and to comment briefly upon these four propositions, in their order.

1*st*. "*That a very large portion of human misery, including poverty, disease, and crime, is induced by the use of alcoholic or fermented liquors, as beverages.*"

This is sophistically, or, I might say, artfully put. What is here asserted of the *use* of alcoholic drinks, can only be true of their *abuse*. But surely, "*ex abusu non arguitur contra usum.*" Whoever, therefore, signs this axiom, worded as it is, signs what is not only untenable, but false;—in my opinion false, both in a physiological and vernacular sense.

2*nd*. "*That the most perfect health is compatible with total abstinence from all such intoxicating beverages, whether in the form of ardent spirits, or as wine, beer, ale, porter, cider, &c.*"

This is partly true; but only partly so. No doubt, in sound and robust persons, "perfect health" may be maintained under almost every variety of diet; but can the same be said of the feeble, the leuco-phlegmatic, and the aged, and more especially of those who labour under the congenital misfortune of a strumous constitution? Have the eminent medical characters, who have signed the above sweeping aphorism, never had occasion to order wine, porter, or ale, to the scrofulous, the emaciated, or the atrophic? If they have so done, is there not some inconsistency in their signing such a document as the above? They may, perhaps, say that they have ordered alcoholic beverages, in such instances as *medicines*. But this will hardly avail them as an excuse; for medical men do not generally order, even as medicines, things that they believe to be intrinsically hurtful.

3*rd*. "*That persons accustomed to such drinks may, with perfect safety, discontinue them entirely, either at once, or gradually, after a short time.*"

This, like the preceding, is only partially true. The young or vigorous may, probably with safety, lay

aside all stimuli; but there are many who could not take such a liberty with impunity. The system will not always bear sudden revolutions of diet, whether from moderate indulgence to total abstinence, or *vice versa*. Most constitutions will suffer more or less, from the revulsion. It has been said that "men are mere machines," but those who try abrupt experiments of this kind, will be apt to discover the contrary to their cost. I could cite more than one instance of persons who had lowered their vitality to such an extent by uncalled-for "pledges" of teetotalism, (I say uncalled-for, because these persons had never been otherwise than temperate,) that they succumbed almost without resistance, to the casual attack of some illness, which ought not, and under ordinary circumstances, would not have proved mortal.

4th. "*That total and universal abstinence from alcoholic liquors would greatly contribute to the health, the prosperity, the morality, and the happiness of the human race.*"

This is sheer declamation, or at least, a begging of the question. Its logical value in the way of argument, is not worth a rush! Might it not be affirmed with as much, or even more truth, that "the universal and rational enjoyment of alcoholic liquors, in common with the other comforts of civilized life, would contribute to the increased health, prosperity, and happiness of the whole human family?"

After what has been advanced, I need scarcely say that I, for one, would steadily decline (however, and by whomsoever importuned,) to affix my name to the above propositions. But do I condemn those who, judging otherwise, have thought fit to sign them? Certainly not. I am aware that men's minds ever vary,—that what seems true to one, seems false to another, exactly according to the point of view in which things are looked at. I well know that there is scarcely a subject under heaven, great or small, on which a discrepancy of opinion does not exist; so much so, that a sincere inquirer often feels no little mental perplexity, and is tempted to ask with Pilate, not scoffingly, but mournfully and despairingly, —"What is truth?" Since, then, there cannot be unbroken unity, let there at least be unbounded charity, amongst us. "Are we not all brethren?"

But without reference to the signing of the above four propositions, a graver question remains behind, namely, as regards the real *tendency* of teetotalism. Is it a popular movement of such a nature as to deserve the countenance and sanction of the medical profession? I humbly think not. I am deeply distrustful of all schemes of human reformation that are not based on the higher motives and feelings of our nature. I deliberately think that Christianity is the only influence that can have sufficient power and authority to control the passions, or to amend the conduct of the mass of mankind. I do not approve of fanciful and fragile human devices, like the ostentatious *pledge* taken in public, (with its usual accompaniments of popular applause,) usurping the place of law and gospel, and claiming an amount of authority at least equal to that of religion itself. It requires no extraordinary sagacity to foresee what the ultimate issue of all this must be. "It is not, and it cannot come to good." It will, should it happen to last, gradually induce a godless turn of thought, akin to the "rationalism" which has worked such mischief in modern Germany; for although teetotalism does not ostensibly disparage religion, it virtually sets its aside, by introducing and familiarizing to the public mind, certain motives and rules of action, other than Christian.

It surely behoves the great and the influential of our profession to "ponder well," before they lend their names to bolster up any novelty of such spurious origin, and fraught with such equivocal, or rather unequivocal consequences. The blessed Founder of our religion, has nowhere forbidden the use of wine. Quite the contrary: witness his first miracle. He has only forbidden the excess, not the legitimate indulgence.

I must now conclude, sincerely begging pardon for occupying so much of your valuable space. I have claimed for myself freedom of opinion and freedom of speech. But "*hanc veniam petimus damusque;*" I cheerfully concede to others what I have thus claimed for myself. I am conscious of no wish to hurt any man's feelings, or to offend even his innocent prejudices. Here then, the matter shall rest, so far as I am concerned. I am pre-determined not to be drawn into controversy.

I am, Sir,
Your faithful servant,
A. ROBERTSON, M.D.

Northampton, May 25, 1847.

General Retrospect.

PATHOLOGY.

RIGIDITY OF THE ARCH OF THE AORTA.

Dr. Bellingham has called attention to a condition of the arch of the aorta, which he states is often mistaken for regurgitant disease of the aortic valve, viz., rigidity and inelasticity with more or less weakness of the parietes of the vessels, with or without dilatation. His views of the production of dilatation of the aorta, are, that it is due to regurgitation of the blood from the carotid arteries into the inelastic vessel, and not as is commonly supposed, to the distensive force of the left ventricle acting upon the diseased arterial coats. The paper, which is one of much interest, terminates in the following *resumè*:—

1stly. That under certain circumstances the blood regurgitates into the arch of the aorta from the carotid and subclavian arteries during the diastole of the ventricles.

2ndly. That regurgitation into the arch of the aorta occurs whenever the coats of this vessel have become rigid and inelastic from previous disease.

3rdly. That regurgitation into the arch of the aorta from the carotid and subclavian arteries is capable of developing a sound, which has a great resemblance to the *second sound of the heart*, and is audible at the same period of the heart's action.

4thly. That a rigid and inelastic condition of the coats of the arch of the aorta, combined with roughness

of the interior of the vessel, and slight increase of its calibre, is characterized by certain well-marked physical signs, which will enable it in the majority of cases to be readily diagnosed.

5thly. That the physical signs of this morbid condition of the arch of the aorta resemble those of valvular disease, and have probably often been mistaken for it.

6thly. That the form of valvular disease with which it is most liable to be confounded, is a state of the semilunar valves of the aorta permitting regurgitation, which it resembles in a murmur accompanying the second sound of the heart, in the jarring pulse, and in the visible pulsation in the arteries; symptoms which heretofore were supposed to be pathognomonic of regurgitations through the aortic orifice.

7thly. That the morbid deposits which occur in the arch of the aorta are not the result of inflammatory action either of an acute or chronic character; neither can they be considered as the result of the natural degeneration which the tissues undergo in advanced life; but that they ought to be ranked among adventitious deposits.

8thly. That dilatation of the arch of the aorta is more frequently the result of regurgitation into this vessel from the large branches which come off from it than of the increased force with which the blood is propelled by the left ventricle, or than of any impediment to its passage through the remote or terminal branches of the aorta.

9thly. That our knowledge of the fact that regurgitation into the arch of the aorta occurs in cases where this vessel has become inelastic from disease, enables us to explain the cause of the *second sound* heard *in cases of aneurism of the arch of the aorta*, and to account for the second impulse felt where the aneurism forms a tumour externally.—*Dublin Medical Press*, April, 1847.

SURGERY.

ON THE EMPLOYMENT OF ISSUES.

By Dr. Brownless.

After a severe but just criticism upon the ordinary method of employing issues, the author gives the following account of his own notions upon the subject. He observes:—

I would recommend, instead of using the remedy in the manner which I have condemned, in the foregoing paragraphs, a method which, as I shall presently attempt to explain, seems to have reason on its side, and of the great value of which I have fully satisfied myself by experience.

Issues should be made of moderate size, and before the effects of the one first made are lost, by the process of repair of the ulcer being completed, another should be made at a distance from the former, so as to act upon another part of the joint affected; (for here I may be allowed to mention that this is frequently required in joints of considerable size, an issue on one side of a joint often relieving the side to which it is applied, but seeming to have little effect on the part of the joint remote from it.) Before the ulcer made by the last formed issue is nearly healed, a fresh portion of the skin should be destroyed by the caustic, and again and again should this process be repeated varying its position around the joint; and thus should a regular diversion from the diseased part be kept up.

There may be reasons in some cases for not carrying out this plan to the letter, as regards the destruction of fresh portions of skin on each application of the caustic. In such cases, or where the patient has great objections to it, a new plot of skin need not be destroyed on each occasion that the caustic is used, but Sir B. Brodie's plan of frequently rubbing the old sore with caustic may be adopted; but, as a general rule, I do not consider it so efficacious as the destruction of a fresh portion of skin, nor is the benefit so lasting, and consequently, the caustic requires to be applied much oftener than where fresh skin is destroyed. Undoubtedly the latter is attended with more pain; but its duration is short, and it is not followed generally by the irritative consequences of blisters, and some other counter-irritants, or, I may add, of issues, kept open by peas and pressure. Scars may be regarded as one inconvenience arising from this plan; but if we can obtain greater benefit to diseased joints by the application of the caustic to fresh portions of the skin, the scars appear to me of trivial importance, even in the case of the fair sex; for the joints, commonly the seat of the disease, are, for the most part, clothed, or at any rate may be kept so without any great drawback to the personal charms of any young lady.

The introduction of peas or other bodies for the purpose of keeping issues open, I would in no case recommend. If from any cause it be judged fit to keep open the same issue, let it be touched with caustic, but not kept open, even in this way, for any great length of time, or it will become comparatively useless.

During the treatment of a very considerable number of cases in which I had the opportunity of employing issues in this way, I found it to be the most efficacious mode of using them; and the principle, although not carried so far, has been fully confirmed in my mind, in a very extensive field for observation, by watching attentively for several years, the patients under the care of Mr. Vincent, in St. Bartholomew's Hospital.—*Lancet*, April 24th.

EXOSTOSIS AND ITS TREATMENT.

M. Roux terminates a long memoir on this subject with the subjoined conclusions:—

1. Among the various tumours of bones, there are certain to which alone the term exostosis is applicable, and which should be carefully distinguished from all others.

2. These, like the bones themselves, are composed of spongy tissue, enclosed in a more compact shell, or in other cases of the compact tissue only, in which case they resemble ivory.

3. Every exostosis of this kind is joined to the bone, from which it springs by a short narrow pedicle.

4. These tumours never surpass a certain degree of development.

5. Their volume is in general proportinate to the size of the bone from which they spring, being small on small bones, large on those of greater dimensions.

6. In general also they are not connected intimately to the soft parts by which they are surrounded.

7. They do not undergo degeneration, but preserve their primitive structure for an indefinite time; the only change which they experience is that of density.

8. These tumours produce a variable degree of inconvenience, according to their locality.

9. They might always be removed, if in some they were not inaccessible from situation.

10. They may be removed without being previously exposed, and though in some cases the operation is followed by severe consequences, it is in general successful.—*Revue Medico-Chirurg.*, Mars, 1847.

SIGNS OF FRACTURE OF THE CERVIX FEMORIS.

In allusion to a case recently occurring in the person of a woman, aged 53, M. Velpeau made the following remarks:—"Pain and swelling are signs of little consequence, as they may equally exist in fracture or sprain. The impossibility of *raising the heel from the bed* is a sign. It may certainly be present also in a painful affection of the joint; but in the fracture of the cervix there is an absolute impossibility of raising the limb, while in this other affection this may be done if the pain be disregarded. Thus, in a luxation, the patient seems at first unable to raise the limb, but he can do so by perseverance. *Eversion of the foot* is not a pathognomic sign, as it may exist in other lesions,—*e.g*, luxation on to the pubis; but in the case of luxation, not only is the limb everted, but neither the patient nor the surgeon can change its direction, while in fracture the surgeon easily turns the foot inwards. There are other affections in which the foot is rotated outwards, as in paralysis, and certain painful affections of the hip. The *admeasurement* of the limb is of great importance, but it is of much more difficult accomplishment than is generally believed. The inclination of the axis of the pelvis, or of the limbs themselves, often gives rise to apparent differences, against which we must be on our guard. We must never depend on mere inspection, but must carefully measure the limb after having placed the patient on his back, and take care that he lean neither to one side nor to the other. In these persons, and in those in whom the bony points is prominent, it is easy enough to measure from the iliac spine to the upper edge of the patella; but there are persons in whom the iliac spine is so rounded off, that we cannot be certain that we are applying the tape upon exactly corresponding points upon the two sides, and an apparent difference, amounting to some lines, may result. So also the patella is not only a fixed point, but its superior angle may be somewhat higher on one side than on the other. In this way several slight errors conjoined may give rise to the belief in a shortening, which has no real existence. By carefully guarding against any obliquity of the pelvis, ascertaining exactly the position of the superior anterior spinous process, and carrying the tape down to the malleolus, instead of the patella, we shall avoid all serious errors.—*Medico-Chirurgical Review*, Jan., 1847; from the *Gazette des Hôpitaux*, No. 68.

NEW OPERATION FOR INTERNAL PILES,

This method consists in the circular cauterization of the pedicles of the tumours with the solidified caustic of Vienna. The dangers which attend excision, and the hæmorrhage so frequently observed as a consequence of that operation, have induced many practitioners to prefer the actual cautery; but this method is one of difficult application, and the results which it yields scarcely compensates for the suffering which it causes. The new operation, according to the inventor, M. Amussat, is more fortunate in its results, exposes the patient to no danger, and to less pain than the other methods.

M. Amussat does not think it necessary, after destruction of internal piles, to remove also those tumours situated below the sphincter; he is of opinion that they materially subside after the cure of the internal hæmorrhoids. The intestine having been cleared by a dose of castor oil, exhibited one day before the operation, the hæmorrhoidal tumour is seized with a forceps, and, in order to protect perfectly the surrounding parts, they are isolated by the application of wooden or ivory blades, analogous to those of paper-knives. Another forceps containing the caustic on the inside of its branches, is then passed round the neck of the swelling, and cold water is injected over the tumour with a syphon throughout the operation, viz., two minutes. The hæmorrhoid is then emptied of its blood by a puncture with a tenaculum, a cold injection is made, and the parts are reduced. Three cases of success are reported; no accidents followed the use of the caustic.—*Medical Times.*

TREATMENT OF STRICTURE OF THE URETHRA BY HYDRAULIC DILATATION.

Mr. Goodman, of Manchester, in a late number of the *Medical Gazette*, relates the following case:—A man applied to him for relief, having a stricture in front of the bulb, of old standing. Four months before a small-sized bougie could with difficulty be passed, and on the time of application to the narrator of the case, total retention had ensued, after drinking freely of beer. An attempt was made to reach the bladder by appropriate bougies, but ineffectually, and it was therefore determined to have recourse to the forcible application of warm-water injections to the strictured part. After introducing a gum catheter as far as the stricture, where it was well secured by a band of tape, and compress placed upon the penis to prevent escape, a syringe-full of warm water was injected with some force, and was found to pass with tolerable ease. On removing the apparatus the man micturated immediately in a stream about the size of a crow-quill. A second application caused a still farther increase in the stream of urine, and the patient left for the time perfectly relieved.

MERCURIAL ACTION NOT A PREVENTIVE OF SECONDARY SYMPTOMS.

Mr. Holmes Coote has written a short paper for the purpose of showing that the full and distinct action of mercury, though it cures the primary symptoms of syphilis, is not the sure preventative of secondary contamination which it is commonly thought to be. To prove this he has recorded fifty consecutive cases of patients suffering from severe secondary and tertiary symptoms, of which seventeen are related in the

present communication, from the analysis of which he determines that mercury is unable to eradicate the venereal poison.—*Lancet*, April 24th.

DIAGNOSIS OF A MERCURIAL SORE.

In a valuable course of lectures on syphilis, Dr. Porter gives the following as the characteristics of the mercurial in contradistinction to the venereal sore:—

1. Mercurial sores are not necessarily circular or oval in shape, neither are their edges regularly defined; on the contrary, they vary in these particulars, and assume different forms as they spread: their edges are often quite ragged, loose, and undermined, and their borders are often marked with a thin transparent cuticle, like that of a newly-formed cicatrix, extending quite around them, and giving them a silvery-white appearance.

2. The bases of mercurial sores are not hard, neither are their surfaces covered with the tenaciously adherent lymph so characteristic of venereal; on the contrary, the surface of the mercurial ulcer may present every variety of shape and appearance, sloughy at one spot, deeply excavated and rapidly ulcerating at another, with exuberant granulations at a third, and exhibiting a tendency to heal at a fourth.

3. But the most striking characteristic of the mercurial ulcer is, its tendency to spread, and the manner in which it enlarges itself. Venereal sores when not affected by phagedena increase slowly, and having reached a given size remain so: the mercurial generally spread quickly, and there seems to be no limit to the size they may possibly attain. I have seen an ulcer as large as my hand in each groin of the same individual. Mercurial sores, too, are easily distinguished from the venereal when they assume an herpetic character, and heal in one part whilst they are spreading in another, which the latter never do: this latter diagnostic is often extremely valuable in ulcers of the throat and on the penis, where any extensive loss of parts may be most sensibly felt during the life of the patient. The mercurial ulceration, too, often attacks the cicatrix of a recently healed chancre, and a fresh sore is thus formed—a circumstance that does not happen to the true venereal sore, except by some accidental injury, or the application of a new infection.—*Dublin Medical Press.*

TREATMENT OF CONSTITUTIONAL SYPHILIS IN THE INFANT.

M. Trousseau has for several years followed the subjoined plan of treatment in these cases with success:—

He administers daily to both mother and child a sublimate bath; (Hydrarg. Bichloridi, dr. iij.—dr. vi.; Alcohol, oz. iij., to a common bath.) If the infant is nursed by the mother the latter is made to take the proto-iodide of iron; if the child is weaned it takes ten drops of the following solution three times a day:—R. Hydrarg. Bichlor., gr. iv.; Aquæ, Oij. The dose amounts to about a 60th part of a grain.—*Gazette Méd.*, Févr. 6, 1847.

FORENSIC MEDICINE.

QUESTION OF IDENTITY: ARE CICATRICES INDELIBLE?

Medical Jurists have foreseen the case in which the condition of a cicatrix may be regarded as a means of proving identity, and they have, moreover, mentioned the circumstances which may so alter their appearance as to prevent them from being recognized. But instances of the actual necessity of referring to these marks in a medico-legal inquiry are comparatively few. The following case is one of the kind:—An Englisman, who was sentenced in 1828, to ten years' imprisonment and labour for forgery, obtained his dismissal after a brief period, on the condition that he should quit the country for ever. While in prison it so happened that he was inspected by the surgeon, M. Vandalaer, who remarked an indelible cicatrix of a burn. Having settled in France he was again pursued for forgery, and the police finding that he had returned to Brussels under an assumed name, demanded him to be given up. He was immediately arrested, but denied that he was the individual in question, in consequence of which he was transferred to Brabant to be identified.

At the trial the prisoner still persisted in his denial. Some of the officials of the prison thought they recognized him, and others could swear to his identity, but no positive proof was forthcoming. The circumstance of the cicatrix was then recollected, and surgeons were called to examine the part. M. Vandalaer, in the first instance, was asked whether he recognized the mark, and replied that he did not, but that he did not consider its absence a proof of non-identity, as time and artificial means might have contributed to its removal. The same opinion being held by other medical men, the prisoner was convicted. It appears from the evidence of one of the surgeons, that the prisoners who are branded are in the habit of removing the cicatrix by placing over it a salted herring.(?)—*Gazette Médicale*, Avril 3, 1847.

Medical Intelligence.

THE MEDICAL REGISTRATION BILL.

HOUSE OF COMMONS, Tuesday, May 14, 1847.

Mr. Wakley moved that the subjects of the registration of legally-qualified practitioners in medicine, and the state of the laws relating to the practice of medicine in Great Britain and Ireland, be referred for consideration to a select committee, who should report the evidence, with their opinions thereon, to the House.

After some remarks by Mr. Wakley on the advantages to be expected from a committee of inquiry—

Sir G. Grey observed, that although he did not think the objections which had been urged against many parts of the Bill of the hon. member for Finsbury ought to prevail, he was convinced that if that measure had been pressed now, any chance of satisfactory legislation on the subject during the present session would have been hopeless. He considered that the hon. gentleman was taking the more judicious course in asking for the appointment of a committee, before whom the various conflicting opinions which existed on this question might be expressed; and he (Sir G. Grey,) believed that such an inquiry would tend to lead to satisfactory results. He was willing to accede to the motion, on the understanding that the hon.

member for Finsbury would not proceed with his Bill until after the committee had made a report.

MAY 22nd,

Committee nominated: Mr. Wakley, Mr. Macaulay, Sir James Graham, Mr. G. Hamilton, Mr. Bannerman, Mr. Acland, Mr. Hawes, Mr. Fitzstephen French, Sir Robert Harry Inglis, Mr. Dennistoun, Viscount Sandon, Mr. Boyd, Mr. Aldam, and Mr. Lascelles.

Power to send for persons, papers, and records. Five to be the quorum.

LEEDS HOUSE OF RECOVERY AND FEVER HOSPITAL.

We have just received the Annual Report of this Institution, for the year ending September 30th, 1846, from which it appears that the number of patients, chiefly fever-cases, admitted during the period, and especially in the last two months, was considerably greater than the usual average.

The average admissions of the preceding ten years amounted to 329.7. The admissions of the year 1844-5, were 329. The admission from October 1st, 1845, to October 1st, 1846, were 433, being 104, or nearly one third more than the admissions of the preceding year, and the general average, which, with 20 cases remaining on the books, give 453 as the number of cases under treatment. The number of deaths was 59, of which, eleven took place within twenty-four hours, and twenty-two others, thirty-three in all, within one week. The mortality was 13.606 per cent. nearly, or not quite, one in seven. The greatest number of admissions was in the month of August, amounting to 69; the smallest number in December and January, 24 in each. The admissions during the six winter months averaged about 30 each month; during the six summer months, rather more than 42; but the increase in the number of patients was wholly in the months of August and September, when the admissions amounted to 128, the monthly average of the preceding ten months being 30.5, or nearly that of the winter season.

The following table shews the ages of the patients and the mortality at each decennial period:—

	Admitted.	Died.
Under 10 years . . .	37 . .	6
10 to 20	173 . .	17
20 to 30	108 . .	11
30 to 40	58 . .	11
40 to 50	33 . .	6
50 to 60	12 . .	1
60 to 70 and upwards	11 . .	6

The chief mortality of the Institution, as well as the chief prevalence of disease, was therefore between the ages of 10 and 30.

QUEEN'S COLLEGE HOSPITAL, BIRMINGHAM.

The efficacy of the inhalation of æther, and the safety of its exhibition in operations on the young subject, was tested on Saturday last, at the Queen's Hospital, in three cases. In the first case, a little boy, from Halesowen, between three and four years of age, labouring under stone in the bladder, was by means of Mr. Atlee's inhaler, put under its influence. The operation with the knife was performed by Professor Sands Cox, and a large stone extracted under the minute, without the poor little sufferer evincing sensibility to pain. In the second case, a little girl, aged nine, a native of the town, suffering under scrofulous disease of the knee-joint, amputation (under the same influence,) above the knee, was rapidly performed by Professor Knowles; not a sigh, murmur, nor the slightest expression of pain escaped her lips. In the third case, a boy, from Bilston, aged 14, with diseased ankle-joint, amputation was performed below the knee; narcotism, in this case, could not be induced, although inhalation was persevered in for more than a quarter of an hour, and the case formed a striking contrast to the preceding.

MEDICAL APPOINTMENT.

It is stated that M. Berard, sen., is to succeed M. Lisfranc, as Surgeon-in-Chief of the Hôpital la Pitiè, Paris.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, May 21st, 1847:—R. P. Bayley; W. H. Brace; H. Tireman; R. Bentley; J. F. O'Leary; H. W. Slack; A. Somers; G. A. Wilkinson; W. B. Deacon; J. Ward; R. N. Bower.

Gentlemen admitted Members on Friday, May 28th, 1847:—D. Badcock; J. R. Lane; C. R. Durell; J. T. Clover; T. S. Collier; T. Rhys; L. Clarke; W. Pritchard; J. A. Simons; R. Davies; J. C. Inglis; B. Daniel.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, May 13th:—William Thomas Gaye, Minehead; Joseph Delves, Tunbridge Wells; James Lewis Holloway, Charlbury; Richard Dechamp Ball, Plymouth; Joseph Williams, Williton, Somerset; William Watts, junior, Nottingham; Benjamin Daniel, Kingston-upon-Hull; Thomas Robinson, Wellingborough; and Thomas Bridgwater, Glasbury, Breconshire.

Gentlemen admitted Licentiates, Thursday, May 20th, 1847:—Charles King, Southampton; George Milburn, North Shields; William David Wilkes, Salisbury; John Smith, Bishops Lydiard, Taunton; Samuel James Augustus Salter, Poole; Richard Jones, Brackley; Ellis Southern Guest, Manchester; Charles Frederic Augustus Courtney, Ramsgate; William Honner Fitzpatrick, Liverpool.

OBITUARY.

Died, May 11th, aged 58, at Paris, from malignant remittent fever, M. Lisfranc, Surgeon-in-Chief of the Hôpital la Pitié. M. Lisfranc was a member of the Royal Academy of Medicine, and a Knight of the Legion of Honour.

May 11th, at Bath, aged 35, Joseph Channing Pearce, Esq., M.R.C.S., F.G.S., &c.

May 11th, at Fulham, aged 47, Joseph Holmes, Esq., Surgeon.

May 15th, at Bedford, William R. Mesham, M.D., Physician to the Bedford General Infirmary. Dr. Mesham was found dead in the Committee-Room of the Infirmary, having evidently swallowed prussic acid.

May 16th, at Mohill, of typhus fever, Henry Soden, M.D., Medical Attendant of the Union Workhouse.

May 17th, in Regent Street, John Phillips Potter, Esq., Assistant Surgeon to University College Hospital, and Assistant Demonstrator at University College. Mr. Potter died from the effects of a puncture received during a *post-mortem* examination.

May 25th, at Worcester, Thomas Taylor, Esq., Surgeon, of Kidderminster, a Member of the Provincial Medical and Surgical Association.

Lately, at Berlin, aged 55, Professor Wagner, of that University.

METEOROLOGICAL JOURNAL FOR MARCH, 1847.

BOOK RECEIVED.

An Account of the late Epidemic Scarlatina, in Newcastle and its Neighbourhood. By Edward Charlton, M.D., Edin., Physician to the Gateshead Dispensary, Lecturer on the Practice of Physic in the Newcastle-on-Tyne Medical School, &c., &c. Newcastle-upon-Tyne: Richardson. 1847. 8vo. pp. 62.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNIVERSARY MEETING.

The Anniversary Meeting of the Provincial Medical and Surgical Association is appointed to take place at Derby, on Wednesday, August 4th, and Thursday, August 5th.

ROBERT J. N. STREETEN,
Secretary.

YORKSHIRE BRANCH MEETING.

The Annual Meeting of the Yorkshire Branch of the Association will be held at the Cutlers' Hall, Sheffield, on Thursday, June 10th, at twelve o'clock. Members of the Association, or of the profession, who are not members of the Branch, may be admitted as visitors on the introduction of a member.

Any communication connected with the meeting should be made to the Secretary, Mr. Husband, York.

COUNCIL PRIZE.

The Committee appointed at Norwich for the management of the Council Fund for the present year beg to announce that THE COUNCIL PRIZE of £50 will be given for the best Report "On the Cerebral Affections of Infancy."

The prize is open to general competition; the papers to be sent in to the Secretary of the Committee, Dr. Streeten, Worcester, on or before the 31st of May, 1848, each paper to have a motto affixed, and to be accompanied by a sealed envelope, bearing the same motto, and inclosing the name of the author.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due, either to the Secretary of the District in which they reside, or to the Treasurer or Secretary of the Association.

ROBERT J. N. STREETEN, Secretary.

TO CORRESPONDENTS.

Communications have been received from Mr. J. F. Clark; Dr. Addison; Mr. Image; Mr. T. Salter; Mr Mayo; Mr. Trousdale; Dr. Turnbull.

Dr. Basham's Lectures will be resumed in the next number of the Journal.

It is requested that all letters and communications be sent to Dr. Streeten, Foregate Street, Worcester. Parcels and books for review, may be addressed to the Editor of the Provincial Medical and Surgical Journal, care of Mr. Churchill, Princes Street, Soho.

PROVINCIAL

MEDICAL & SURGICAL JOURNAL.

A COURSE OF LECTURES ON CLINICAL MEDICINE.

By W. R. Basham, M.D., Physician to the Westminster Hospital.

Lecture X.

Case of Hypertrophy of the Heart with Dilatation: the accompanying symptoms illustrative of this form of cardiac disease; cough; dyspnœa; peculiar and special form of expectoration; anasarca and general dropsy: stethoscopic signs.—Hepatic derangement; state of the excretions; condition of the urine albuminous; deficient in urea; analysis of the blood, detection of urea in.—General indications of treatment; advantages of venesection.—Singular character of matter vomited from the stomach; the Sarcina ventriculi, *of Goodsir, observed in the yeasty mass ejected from the stomach.*

Gentlemen,—The case to which I wish to engage your attention to-day, is one that I have had frequent opportunities of making passing observations upon during our visits to the wards; but as it has presented many symptoms of complication and difficulty to the student in clinical medicine, I propose to take a general review of the symptoms as recorded in the ward-book, and to give you such explanations as may be necessary to interpret either its pathology or treatment.

G. F——, aged 38, carpenter, has been addicted to drinking; his general health has been good till within the last five weeks. He was admitted into Burdett ward on December 24th, and was then suffering from frequent urgent dyspnœa, with suffocative cough, and copious expectoration, of a very dirty-coloured, glutinous, jelly-like fluid. He states that his health began to give way about five weeks since, first complaining of severe attacks of gastrodynia and tenderness at epigastrium, augmented after eating; cough and dyspnœa followed, and then the legs began to swell, and he noticed that the face became puffed and œdematous in the morning. There was, on admission, general anasarca, the scrotum being distended with fluid; face œdematous, especially in the morning; aspect of the patient not unhealthy, as there is a remarkable injection of the vessels of the cheeks, which gives a florid appearance of health; the conjunctiva has a slight icteritic hue; the surface of the chest is œdematous, the stethoscope leaving an impression by its pressure. The chest is equally resonant throughout; no dulness in the præcordial region; vesicular murmur not clearly heard; bronchial respiration in each region, with deep mucous gurgling of large bubbles; impulse of the heart much increased, the head being sensibly raised by the upheaved stethoscope; the systolic murmur is not prolonged, but the diastolic sound is confounded somewhat with it, it is not clear and distinct; the pulse is sharp and full, regular and equal on both sides; no pulsation noticed in the neck; the cough is frequent; sputa muco-glutinous, and stained by the hæmaphæin of the blood; some slight tenderness on pressure in the lumbar region of the kidneys; the liver appears to occupy a larger space than usual, but there is no tenderness in the right hypochondriac region. He was cupped over the region of the heart, and directed to take the blue pill, in three-grain doses, night and morning, with infusion of diosma and tincture of digitalis.

During the next twenty-four hours the anasarca sensibly diminished, but the heart's action continuing very violent and impetuous, it was thought desirable to take blood from the arm to sixteen ounces. The blood drawn did not separate into its constituent portions of coagulum and serum, but remained a firm uniform coherent red clot, easily broken up, but which did not yield up any serous fluid on being so disturbed. The urine was this day examined. He passed not more than a pint in the twenty-four hours; it was cloudy, of an orange-brown colour, with numerous flocculi appearing in it, faintly acid, cleared by heat, with copious evolution of gas-bubbles; on reaching the boiling point it again became cloudy, and on the addition of nitric acid, a flaky albuminous deposit in minute quantity, was thrown down. Microscopically examined, amorphous urate of ammonia, with considerable amount of epethelial matter, was observed. As he obtained no sleep, being much disturbed by the cough, he was ordered Extr. Conii, gr. x., hora somni.

The impulse from the heart continuing but little diminished, and the pulse being still full and sharp, it was thought desirable on the 31st to take a farther quantity of blood from the arm, and eight ounces were abstracted; and now the separation into serum and clot took place, but there was no separation of the red particles from the fibrin. The effect of this bleeding was most beneficial upon the secreting organs; the kidneys now formed two pints and half of urine in the twenty-four hours, of a lighter colour and clearer, with less deposit of urates. The fæces became of a brighter bilious hue, and the expectoration was more copious and easier of excretion, but still presented a dirty hue, the colouring matter of the blood being still

dissolved in it. The anasarcous condition of the system had much diminished; there was much less œdema of the chest; no swelling of the scrotum; and scarcely any of the lower extremities. On the 2nd of January, the quantity of urine excreted is stated as three pints; natural in colour and general appearance; no indication of albumen; normal amount of uric acid; tongue clean; pulse, however, still continued full, sharp, cordy, and jerking. Up to this period the patient had been confined to a fish diet, carefully avoiding all stimuli. The mercurials were repeated only at intervals; digitalis being solely trusted to bring down the impetuosity of the heart's action after the *plenitudo ad molem* had been to a certain extent relieved by venesection.

The report of the 4th of January states that the urine had again diminished to a pint and a half, of a brown orange colour, and much loaded with urates. The heart's impulse still continues augmented; sounds somewhat obscure; an aortic bruit accompanies the systolic murmur, increased and becoming more distinct as the stethoscope is raised to the position of the arch of the aorta. On the 6th of January the urine became again highly loaded with urates; albumen in small quantity still present; bowels continue to act freely, but the dejections are offensive and dark coloured; pulse 120, full and incompressible; cough frequent and distressing; sputa as before, but without any trace of blood; heart's impulse much increased; action impetuous. Blood was again taken from the arm to eight ounces, a portion of which was analysed by the following process, to ascertain if urea existed in the blood. As soon as drawn, three ounces were agitated well with pure alcohol, and allowed to stand at rest for four hours; the mass was then filtered, and the residue on the filter again treated with alcohol, and the solution filtered. An orange-coloured alcoholic solution was obtained, which was evaporated to dryness in the water bath, after three fourths of the alcohol had been recovered by distillation at a low temperature. The dry residue had a yellow orange colour, and a faint crystalline appearance; a few drops of distilled water were added, and then a small quantity of pure nitric acid; on setting this aside in a watch-glass in a cool place, after an hour's rest, crystals of the nitrate of urea were distinguished with the half-inch glass, under the microscope.

It was now thought advisable to allow the system to rest for a time without any interference by medicinal agents, for the last abstraction of blood had materially relieved the more urgent symptoms; the heart's impulse was diminished; the pulse was reduced to 90, softer in character; and the cough was less frequent, and the expectoration free from hæmaphæin and more purely mucous in its appearance. The urine, though still high in specific gravity, (1.021,) was clear, yet dark coloured. No urea could be detected, and the presence of albumen was still indicated by the ordinary re-agents.

On the 9th of January a great improvement became manifest. The anasarcous condition of the surface had disappeared, and the legs only became œdematous towards night, and after he had walked much about the ward; the pulse, however, had become unnaturally frequent, 120, but had lost its jerking character, and the general appearance of the patient was that of a healthy man, from the before-noticed state of the capillaries of the cheeks. The sputa had become much diminished in quantity, and frothy, and colourless, presenting only a few masses of yellow mucus. He was now placed upon an improved diet, three ounces of meat for dinner, with extra bread allowance. Two days after, however, the symptoms again retrograded. The œdematous condition of the legs, scrotum, and entire surface, even of the cheeks, again returned. The urine two pints daily, of a dark orange-colour, with copious deposit; bowels open, dejections natural; appetite craving; pulse 110, full and tumultuous.

The symptoms continued without any material alteration to the 21st of January. During this interval he had taken nitric acid, and subsequently for a few days, quinine, but without any change for the better. On the 21st, after breakfast, he was seized with nausea and vomiting of a peculiar yeasty-looking fluid. The urine during the last few days had become very dark coloured, of a specific gravity of 1.022, and the amount of albumen had very much increased. At the afternoon visit on this day, a rough murmur was heard continuous with the systolic sound, and much obscured by the moist mucous crepitation, heard more particularly in the mammary region of each side. A good deal of restlessness occurred, and morphia was administered at night.

On the 22nd, vomiting again occurred, of the same frothy yeasty fluid. This, when examined by the microscope, presented many fat globules, epithelial scales in abundance, frequent tufts of margaric acid, and several beautiful specimens of the *Sarcina ventriculi* of Goodsir. Ammoniated draughts, in a state of effervescence, with citric acid, were given; and arrow-root, and small quantities of wine, with morphia at night. The ammoniated draught seemed to check the vomiting, for it did not return after the first two doses. During the next three days the œdematous state increased; the heart's action increased in tumultuous impetuosity; the sounds in the præcordial region became muffled; the cough and dyspnœa returned in frequency and urgency; the urine diminished in quantity; the bowels were freely moved; the appetite craving; no thirst, no vomiting. The dyspnœa became more urgent on the afternoon of the 26th of January, and in the evening of that day he died.

Sectio Cadaveris twenty-four hours after death.—The whole surface of the body was anasarcous, the subcutaneous tissues being much infiltrated with clear serum; some also was present in the abdominal cavity. Firm adhesions between the pleural surfaces. The bronchial glands situated at the fork of the division of the bronchi were very much enlarged, as were also those which lay beneath, and followed the direction of the left bronchus. The mucous membrane of the trachea was finely injected, and of a bright red colour, but at the bifurcation this colour had become of a dusky brown, with marked evidence of passive venous hyperæmia; all the tubes were filled with a tenacious fawn-coloured mucus. The heart was very much enlarged, its cavities dilated, and its walls thickened;

it weighed after being cleaned seventeen and a half ounces; the tricuspid valve was opaque and thickened at its edges; the semilunar valves of the pulmonary artery were natural; the aortic valves, however, were rigid, and stood out pouch-like from the parietes of the vessel, and their edges thickened and covered with wart-like fibrinous growths. The aorta for five inches in its extent, was covered with a semi-cartilaginous deposit that presented the walls as wrinkled or corrugated, and with evident enlargement of its capacity by dilatation. The liver on the superior surface of the right lobe presented a copious exudation of plastic lymph, causing firm adhesion to the diaphragm; the substance of the organ was highly granular, and exhibited the features of incipient cirrhosis, the appearance being myristicate,—a purplish veining, surrounding isolated yellow granules. The organ weighed fifty-nine ounces. The kidneys were not enlarged; the right weighed four ounces and three quarters, the left five ounces. The tubuli uriniferi were clearly marked out by a deep purple injection, and the cortical part was granular, plainly demonstrated when the peritoneal tunic was removed; some granular deposit was also observed dipping between the tubular processes. The veins of the stomach both of the lesser and greater curvature, were so gorged with blood as to present a remarkable feature. The mucous surface of the viscus was of a purple madder colour throughout, and the greater part of the mucous membrane of the small intestines presented the same appearance. The mesenteric veins were much distended. The bladder exhibited, as to its mucous membrane, similar conditions to that of the stomach.

The history of this case presents us with all the most characteristic features of hypertrophy and dilatation of the heart; it exhibits also many circumstances illustrating the effects of mal-assimilation, and the consequent diseased condition of the blood. The position these several morbid conditions bear towards each other, it is impossible, with certainty, to define. Whether the heart-disease be the cause, and the other morbid conditions but the effect of the disturbed circulation; or whether reversely, the organic alterations in the heart's structure, be produced by an imperfectly formed circulating fluid, deficient in formative elements, or redundant with morbid material, and capable of exciting the heart to irregular action, it is not possible to determine. It is my wish on all occasions of our meeting for clinical study, to avoid mere speculative or hypothetical points, and to confine myself strictly to an explanation of the symptoms that are capable of illustrating the nature and progress of diseased action. Laying aside therefore the speculative matters just hinted at, let me turn your attention, first, to the more prominent and most characteristic symptoms of hypertrophy, with dilatation; and secondly, to the more complicated condition of deranged secretion and diseased blood.

The earliest symptoms recorded in the case book are those of cough and dyspnœa, accompanied by a peculiar form of expectoration. In searching for the cause or origin of these *pulmonary* symptoms, we fail to detect any specific commencement from an inflammatory attack, or anything analogous to an attack of bronchitis. The patient declared that the cough came on gradually, and became aggravated day by day, in an imperceptible manner, and that up to a certain period, though occasionally troublesome, it did not stop him from his usual avocations. The dyspnœa became subsequently very urgent, and compelled him to seek medical relief. Cough and dyspnœa thus gradually coming on, without any previous well-defined inflammatory attack, may generally be considered as indicative of some deranged condition of the pulmonary circulation, originating in irregular cardiac action. The mucous membrane in these cases is in a state of venous hyperæmia, sometimes called passive congestion; it is livid in colour, turgid, and œdematous, and a dirty-coloured brownish viscid secretion lines the bronchial tubes, and is the main cause of the cough and respiratory distress. When raised and expectorated, the sputa are specially characteristic of the above-described condition of the mucous membrane, differing remarkably from any form of excretion that usually follows inflammatory states of the bronchial tubes. The expectorated matter is glutinous—similar to glue, both in consistence and colour, of a dirty dusky ochre, or fawn colour, sometimes even still darker, as if the hæmaphæin of the blood were dissolved in it. This form of expectoration may be considered very characteristic of venous hyperæmia of the bronchial mucous membrane, arising from heart-disease. The cough commencing imperfectly, the dyspnœa and this peculiar glue-like expectoration may be taken as one series of the symptoms indicative of hypertrophy with dilatation.

The second series embraces the anasarcous condition of the surface of the body, the œdematous condition of the face in the morning, or after sleep, and the general dropsical state of the system generally, the swollen legs, and distended scrotum. The third series of symptoms comprises the altered state of the secretions; the high coloured, orange-tinted, and albuminous urine, deficient in urea, abundant in uric acid and its compounds, diminished in quantity, and of high specific gravity; the dry, acid skin, the icteritic aspect, and the offensive mud-coloured, imperfectly formed fæces. This category of symptoms suggests the heart to be, in a corresponding degree, deranged in function, and probably altered in structure; and though we cannot prove that all these symptoms are severally dependent on the diseased heart as their morbid cause, yet experience teaches us that they for the most part co exist, and that the presence of the above-enumerated series would be presumptive evidence of disease of the heart. The stethoscope amply confirmed this suspicion of cardiac disease, and enabled us to define, to a certain extent, the special form of disease affecting this organ; the impulse of the heart was increased to such an extent as sensibly to raise the head when applied to the chest; the rhythm of the heart's sound was not perfect; the systolic and diastolic murmurs were confounded, the latter merging into the systole, and not to be distinguished clearly from it. There was an aortic bruit heard over the aortic region, continuous with the systolic sound; hypertrophy, with dilatatio

and some organic defect in the aortic valves, were thus detected; but the stethoscope not only indicated these alterations in the structural condition of the heart, upon the admission of the patient, but it enabled us to determine the progressive mischief and changes that were proceeding, unchecked by any of the remedies employed. Notwithstanding that at one time a favourable change appeared to take place, the worst symptoms being suspended, the anasarcous condition having disappeared, the cough and dyspnœa abated, and this consentaneous with a general improvement in the several secerning functions, yet, nevertheless, the stethoscope revealed, even at this period, a peculiar aortic bruit, and on the 21st of January this had increased to a rough murmur, heard most plainly over the aortic valves, and which irregular sound clearly indicated some defective formation of, or adventitious growth upon, the membranous fold. The *post-mortem* examination explained this aortic murmur, and shewed it to have been caused by the fibrinous vegetations found appended to these valves.

The cardiac disease must be accepted as the cause of the dropsy, combined, perhaps, with a morbid condition of the liver, by which the freedom of the portal circulation was checked. The heart endowed by its increased volume of muscular fibre, with an augmented power, forces the arterial current through the aorta and the arterial trunks, with a force disproportionate to the power of the venous capillaries to carry it onward in its return to the right side. The dilated condition of the auricles, especially the right, diminishes the suction power by which the venous blood is in some measure moved towards the heart; the venous current is thus retarded, and general venous hyperæmia produced. Hence the anasarcous state of the whole surface of the body, face, chest, arms, trunk, and lower extremities; and hence also the venous congestion of internal organs, kidneys, liver, mucous surface of lungs, stomach, and intestines, and the consequent alteration in the integrity of their several functions. The distressing state of the respiratory organs, the urgent dyspnœa, is in like manner caused by the heart-disease. The increased power of the right ventricle drives a volume of blood upon the lungs, with a force incommensurate with the oxygenating power of the ordinary respiratory process; venous congestion results. An œdematous state of the bronchial mucous membrane is among the morbid consequences; a mucous secretion, peculiar in its character, forms in the bronchial tubes, and a frequent harassing cough, vainly exhausts the patient in efforts to clear the air-passages from this impediment to the respiratory functions.

Such are the pathological conditions observed in this patient, and now let me detail to you the principles upon which the treatment of such a case should be conducted. Venous congestion, or retardation and obstruction to the venous current of blood, has been pointed out as the proximate cause of the most prominent symptoms; and to diminish the volume of blood moving to the right side of the heart, by venesection, should be our first effort. Blood taken from a vein in the arm, judiciously proportioned as to quantity, quickly induces relief to the more urgent and distressing symptoms, the permanency of which is proportioned in a great measure to the extent of the disease. Internal remedies are feeble in their effects, and uncertain in their operation, till the congested state of the venous system has been relieved by blood-letting. Mercury produces no appreciable effect on the secretions,—digitalis is useless as an internal agent, till the plethoric condition of the system has been diminished. So soon as that has been effected, then these remedies, either separately or combined, oftentimes operate with marked success. You cannot have failed to notice in this case the immediate and sensible relief obtained from the more distressing symptoms, as soon as blood was taken from the arm. The cupping over the region of the heart obtained the effect desired, as far as the threatened or suspected indications of pericarditis were concerned; but it was not till after the bleeding from the arm, that the most evident benefit to the general symptoms was observed, and then also the effects of the mercury and digitalis quickly developed themselves in augmented and improved secretions, and a gradual abatement of the general dropsy. This favourable condition, however, did not continue, as is but too often the case; for it is but temporary relief that can be expected, when this form of heart-disease has made any progress. The urine again diminished in quantity, became more highly albuminous than before; anasarca of the lower extremities returned, but the cough and dyspnœa were not so distressing as on his admission. He was again bled, and the blood was reserved for analysis, to ascertain if urea could be detected in the blood, that element being deficient in the urine, and my object was to gain some additional evidence of the possible existence in the kidneys of that granular degeneration known as the morbus Brightii. At the time this analysis was made, I explained to you the method of conducting it. It is a process requiring much analytic skill. The presence of urea in the blood was determined, and you had an opportunity of seeing the minute crystals of the nitrate of urea under the field of the microscope. I had now no hesitation in believing that a granular state of the kidneys had to be added to the other serious morbid conditions, and with this complication to pronounce a most unfavourable prognosis; and as the prospect of any ultimate relief was very remote, and as injudicious efforts to obtain benefit from questionable remedies, after the general therapeutical indications have been fully carried out, oftentimes only aggravate the symptoms and hasten the catastrophe, it was thought advisable to depend on a simple diet, rest, and the occasional administration of such remedies as the more prominent or urgent symptoms might require.

He gradually got worse, but before his decease there occurred an irritable state of the stomach, with frequent vomiting,—a state of things scarcely requiring notice but for the remarkable character of the vomited matter, and the interesting opportunity afforded me of observing in it specimens of the *Sarcina ventriculi*, of Goodsir. The interest of this circumstance is increased by the fact that the vomited matter in this case appears to

have presented the same peculiar characters as were observed in the case recorded by that eminent microscopist, in his first account of this species, in the *Edinburgh Medical and Surgical Journal*. The vomited matter in that case is described as having the appearance of yeast, and the report in Burdett ward-book of the vomiting of this patient was that it looked like yeast. It was not till the following day that I had an opportunity of seeing this singular yeasty, pulpy mass, which I witnessed being ejected from the stomach. Its appearance was so peculiar that I at once placed it under the microscope, and then I immediately recognized those singular cubic and *bale*-like masses of vegetable development, minutely and regularly marked into sections of quadrupled subdivisions. There were also many tufts of margaric acid, with epithelial cells in abundance. There is much interest in the coincidence of the presence of the *Sarcina ventriculi* in vomited matter of the same physical characters, and it certainly gives force to the opinion of Goodsir, that in special cases the contents of the stomach suffer certain spontaneous or intestine changes, analogous to fermentation, and consequently opposed to the true digestve function, which must for the time be in abeyance, and that as the consequence of this fermentative process, certain vegetable structures are developed, of which the *Sarcina ventriculi* is an example.

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(*Fourth Series of Experimental Researches.*)

By William Addison, M.D., F.R.S., Malvern.

(*Continued from page* 263.)

XIV. Inflammation considered morphologically.

Vague generalizations with respect to the nature of the elements entering into the normal composition of the textures, and a neglect of the order of their appearance in the embryo, may be enumerated as obstacles to a knowledge of the real nature of inflammation and of the import of pathological facts. Among the *mucous* membranes or textures many microscopical distinctions exist; and the same may be said also of the *serous* membranes. The outer covering or *tunica conjunctiva* of the eye-ball, differs from the *intestinal villi*; the *pia-mater*, from the *plexus choroides*, and the synovial membrane of the joints.

In researches directed to the attainment of a knowledge of the morphology of the elements of normal textures, for the purposes of practical medicine, it is important to arrive at some conclusion with regard to the relative values of a microscopical and chemical analysis; and the following considerations have prompted me to trust to the former as the surer and safer guide.

First, the microscopical investigations of Schleiden, Schwann, Henle, Barry, Wharton Jones, Bennet, and others, have contributed to the development of a physiological law or order, by which abnormal changes may be rationally and scientifically tested; whereas chemical philosophers have done nothing in this respect. Secondly, microscopical analysis reveals elements and forms, as nearly as possible as they exist in the living structure,—nay, in the living body itself; whereas, a chemical analysis furnishes only the result of complex manipulations, in which unnatural agents are employed, unnatural changes produced, and unnatural products evolved. Thirdly, the materials for the growth and nutrition of living bodies are prepared or elaborated in the interior of closed vesicles or cells, so that when the cell-wall ruptures, and the interior matter is thereby exposed to new agents, new changes occur; and alterations of form and quality therefore anticipate a chemical investigation. Lastly, vegetable morphology, as a branch of scientific research, owes everything to the microscope, and nothing to the filtering paper, the test-tube, or the crucible; it is therefore reasonable to expect that the normal order of animal morphology may be equally as well illustrated by the same means. Not that microscopical and chemical investigations are to be considered as in any way opposed to each other; on the contrary, the question is, which, in the present state of our knowledge, affords the most useful and trustworthy information. Chemical facts in their relation to the structure and functions of living beings, appear to me, at present, as loose and isolated materials, which may hereafter find their useful applications; but to the microscope will, if I mistake not, belong the credit of enabling us to establish physiological and really practical principles.

In applying the law of morphology in explanation of the phenomena of inflammation, the distinctions between *organs*, *textures*, and *elements*, must be *insisted* on.

In vegetable structures,—leaves, sepals, petals, stamens, and carpels are organs.

It has been shown (I., p. 33) that leaves are composed of two distinct cellular textures, (the coherent respiratory, and the incoherent secretory,) of a supporting fibrous texture, spiral vessels, and stomata. The same kind of demonstration may be extended to all vegetables organs.

It has also been shown, (I. and II., pp. 33 and 61,) that the elements contained within the secretory cells are either a viscous protoplasma mixed with molecules, green granules of chlorophylle, with sundry properties and qualities; or (as in petals,) a coloured fluid with molecules. The differences in these elements being due to an elaborating process effected within the closed cells in obedience to a fixed morphological law.

The same kind of demonstration may be extended to animal structures. In the human body, for example, the liver, the lung, the brain, the kidney, and a bone, are organs; each organ being composed of various

textures, and each texture of special histological or morphological elements. Thus, the liver, which is a secreting organ, has the following textures and elements entering into its composition :—

1. *The hepatic parenchyma.*—A brittle, slightly-coherent, corpuscular texture, the elements of which are cells, containing in their interior a yellow fluid, with numerous molecules and globules of fatty matter, (together forming a kind of animal endochrome,) which, when set free by the dissolution of the cell-walls, constitutes the secretion termed the bile. The cells are congregated in small groups, termed lobules, each lobule having its own vessels and ducts.

2. *The areolar texture.*—A coherent elastic texture, interposed between the lobular sub-divisions of the hepatic parenchyma, and forming a cushion or bed around the divisions and sub-divisions of the blood-vessels and bile-ducts. This texture is diffused throughout the whole organ, enters into all its recesses, and with the blood-vessels and bile-ducts, interposes between the lobules. The elements of this texture are waved fibres and curled fibrils.

3. *The hepatic indusium,* or peritoneum.—A thin membranous texture, which limits the external configuration, and gives a smooth equable surface to each lobular sub-division, and to the whole organ. This texture is coherent cellular externally, and fibrous beneath, where it is continuous, and blends with the areolar texture just described.

4. *The coats of the larger divisions of the blood-vessels and bile-ducts.*—This is a strong fibrous texture, differing from areolar texture by the fibres being straighter and condensed into layers, which cross each other at right angles, and inclose among them cell-like bodies termed *nuclei,* numerous molecules, and granular or fatty particles. The elements of this texture therefore are fibres, nuclei, molecules, and granules; and its nutrient vessels are technically called *vasa vasorum.*—(IV., p. 92.)

5. *The mucous texture of the interior of the bile-ducts.*—The elements of this texture consist of cells and fibres; the cells at the free surface are denominated epithelial cells, and when detached from the texture in an early unmetamorphosed globular form, are called mucous cells, or mucous globules.

The lung is composed of the following textures and elements:—

1. *The pulmonary parenchyma.*—An elastic, coherent, cellular texture. The cells of this texture are comparatively very large, and inclose spaces filled with bubbles or vesicles of air. The elementary membrane forming the cell-walls is thin and transparent, but strong and elastic, and covered all over with a close network of non-secreting capillary blood-channels.—(IV. and V., p. 92.)

2. *The areolar texture,* with the same elements, and performing the same kind of office as the areolar texture of the liver.

3. *The pulmonary indusium,* or pleura, limiting the external configuration of the organ, and of the same nature with its analogue in the liver; and although we may give to the *indusium,* or to the *lobular indusia,* of one organ, one name, and to those of another organ, other names, still it behoves us not to neglect the identity of their structural elements, nor their physiological and pathological relations.

4. *The coats of the larger divisions of the blood-vessels and air-tubes.*

5. *The mucous texture of the interior of the air-tubes.*

6. *The fibro-cartilaginous and cartilaginous textures of the windpipe and larynx.*

In the leaves of plants, a coherent transparent non-secreting aëriferous texture, with air spaces and stomata, and an incoherent, secreting, corpuscular, chlorophylle texture, with a supporting frame-work and spiral vessels, are conjoined, and co-exist; whereas it would appear, from the details of the structure of the liver and lung, that in animal bodies, the coherent transparent, non-secreting, aëriferous parenchyma, with its necessary appendages of air-passages and air-tubes, and the secreting, endochrome, corpuscular texture, with its requisite ducts and outlets, are separated, and form two distinct organs.

In the lung, (V., p. 92,) the fibrous elements of the texture of the larger divisions of the blood-vessels and air-tubes are continuous with, and terminate in, the coherent, non-secreting, cellular parenchyma; so it appears in the liver, and probably in other secreting organs, that the fibrous textures of the blood-vessels and ducts are disseminated, (in the capillary channels,) among the secreting cells of the corpuscular parenchyma. (IV., p. 92.)

The analogous fact may be seen in the embryo chick, where the walls of the vessels of the *respiratory* allantois are quite different from those of the *nutritive* yolk-sac.

Of the several elements of the liver and lung here enumerated as typical of the composition of the organs of the human structure, it is to be observed, that some are general, some peculiar, and in all cases it is the peculiar parenchymatous elements that constitute the distinctive character and execute the special function. The slightly coherent endochrome, and transient cells of the hepatic parenchyma are peculiar to the liver; the strongly coherent, vascular, permanent, aëriferous cells of the pulmonary parenchyma, peculiar to the lungs; muscular fibrillæ, to muscles; and nerve-tubes to nerves. But the fibrous elements of the coats of the blood-vessels, and of the areolar texture, are general, so that no visible part of the body, however small, is without them. Hence, every perceptible alteration of structure involves not one only, but many textures,—the parenchymatous texture, the texture of the coats of the blood-vessels, the areolar textures, &c.

A retrograde metamorphosis in the parenchymatous texture of the brain, lung, joints, and bones, cannot take place without sundry degrees of morphological transformation in the contiguous textures. In the lung the fibrous texture of the coats of the blood-vessels, the fibro-corpuscular secreting texture of the air-tubes, the lobular indusia, the areolar fibrous texture between the lobules, and, finally, the pleura itself, all partake in the phenomenon. Thus, during the progress of consumption, there is an increased secretion from the air-tubes; a thickening of the interlobular areolar textures; destruction or thickening of the coats of the blood-vessels; and, finally, adventitious membranes and abnormal secretions on the pleura. If ulceration of the mucous texture of the air-tubes occur, the fibrous texture beneath is thickened and consolidated; and when the secreting texture of the alimentary canal softens and ulcerates, pseudo-fibrous membranes glue the convolutions of the bowel to each other, one texture retrograding into a fluid pus, whilst adjacent ones, of a higher type and different order, are becoming thicker and more consolidated,—scrofulous and inflammatory actions running on together, not in the same texture, but in the same organ.

Amidst the manifold phenomena, and the multitude of qualities and textures produced, during the growth of living bodies, and during the progress of scrofulous and inflammatory diseases, by the agency of cells, the following two events appear constant and influential:—

1. The enlargement of the capacity of some cells, the thickening and coalescence of their adjoining walls, and their durability in sundry forms as persistent elements of the fabric.

2. The transient existence of other cells, the thinning and dissolution of their walls, and the consequent discharge of their contents,—a gelatinous, fibrillating protoplasma, or a limpid secretion.

And as cells (I. and II.) are—

1. *Incoherent and fluid*, in blood, pus, &c.;

2. *Slightly coherent*, forming soft and brittle solids, in the brain, the hepatic parenchyma, and the corpuscular secreting textures; or,—

3. *Strongly coherent*, in the parenchyma of the lung, in the pith and leaves of plants, and in woody and osseous textures.

So the protoplasma may be—

1. *Incoherent, gelatinous, and fluid*, in lymph, liquor sanguinis, mucus, saliva, and other secretions;

2. *Slightly coherent and granular*, in the flakes and clots of pus, tubercle, tuberculous matter, &c.; or,—

3. *Strongly coherent and fibrous*, in coagulated fibrin, in the areolar and ligamentous textures, and in false or adventitious membranes.

Combinations of these cellular and protoplasma elements give rise to textures of sundry kinds, and of various degrees of cohesion,—to *gelatino-corpuscular*, or *gelatino-cellular*, *fibro-cellular*, *fibro-granular*, &c. In the egg of a bird we have an example of a gelatinous protoplasma, derived from cells in *the white*, and of a slightly coherent, cellular, or corpuscular texture (the cells abounding in granular matter,) in *the yolk*. And in all cases the normality or abnormality of the prevalent elements must be determined by the natural type or standard, by their conformability or unconformability to the law of the morphology, or the law of the growth and nutrition of the structure.

It has been shewn in the blood-vessels ministering to the growth of the transparent textures of the human embryo, that we are sometimes able to discriminate with the microscope the red blood in the centre of the vessel (*a*); a layer of protoplasma (*b*); the texture of the wall of the vessel (*c*); and the parenchyma (*b.*) (VII., *Fig. I.*, p. 117.) And it is evident, if unconformable elements accumulate in the protoplasma space (*b*), that they must, in the progress of nutrition, mingle with or supplant the normal elements of the coats of the vessel (*c*), and thence enter into the composition of the parenchyma (*d*), ultimately appearing in the secretion (or excretion,) if the texture be a secreting one, or being eliminated from a non-secreting (or non-excreting,) one, they constitute an abnormal discharge. Unconformable and incoherent cells predominating, alter the physical properties of the coherent textures; and if they supplant the normal elements, the texture is said to *ulcerate*.

In the blood-vessels which traverse the transparent, adult, fibrous, or areolar textures, we see no indication of a protoplasma space; nor do we find incoherent, cellular, or corpuscular forms interposing between the red current and the walls of the vessels, and it is on this account inferred that nutrition and growth are not going forward actively in such vessels. But when these textures become inflamed, not only are the vessels multiplied in number, but their walls become thicker; uncomformable, cellular, and protoplasma elements make their appearance between the blood-current and the texture, occupy the intervals between the normal fibrous elements, accumulate on the exterior of the vessels, and are cast off in the excretions. Hence, then, we see the propriety of the terms *protoplasma* and *protuphasma*; for lymph, in the ordinary acceptation of the term, is only one of the forms of the nascent, nutrient, metamorphosing matter; and the walls of capillary vessels differ in different textures, differ in the same place in the embryo and growing from the adult texture, and are subject to sundry alterations in inflammatory and scrofulous diseases.

(To be continued.)

ON THE PATHOLOGY AND TREATMENT OF PERTUSSIS.

By George Fife, M.D., Newcastle-onTyne.

On no disease of common occurrence, has a greater diversity of opinion apparently existed as to its true pathology or seat, than, even at this time, prevails in regard to that of hooping cough, If, in support of this statement, any evidence should be required, such is abundantly afforded by a consideration of the very numerous and diverse remedies which have been recommended for its mitigation or cure. Hence, no apology seems requisite for the obtrusion of the present remarks on this peculiar and interesting disease upon the attention of the Association. To enter into a full enumeration of the various causes to which it has been assigned, would occupy more of time and space, than the limits of this paper permit, consequently, for the present, I will restrict myself to the consideration of what may be termed the two principal doctrines which modern practitioners hold on the subject.

One of these parties may be said to maintain the inflammatory nature of hooping cough, and to consider it as essentially a form of bronchitis; the other regards it as a peculiar nervous and spasmodic disease, and specific in its character.

The former opinion I believe to be advocated by the majority of the profession, whilst to the latter, for reasons which will be apparent in the sequel, I, after extensive practical observation, and the most mature consideration, am disposed to give my support.

Fashionable as it now is to impugn and even to ridicule the nosological division of diseases by the illustrious Cullen, I am free to admit, that in his definition of pertussis, he has not only been most happy, but has also rested his views on what is perfectly compatible with the most recent pathology. His definition I will now therefore give, prior to entering upon the the more particular consideration of the pathology of the disease itself:—

"Morbus contagiosus; tussis convulsiva, strangulans, cum inspiratione sonora, iterata; sæpe vomitus."

The first proposition in the above, as it has but little reference to the actual nature of the morbid action going on, may be passed over with comparative brevity. Of the epidemic prevalence of hooping cough every practitioner of any experience must be perfectly satisfied, and but few will be found to deny, that if the term *contagious* be used as synonymous with *infectious*, even on this point the definition of Cullen is correct, and it is more than probable, that such is the sense in which it has been used, however objectionable it may be to confound infection, properly so called, with contagion, taken in its strict and literal sense. Of its infectious character I could adduce ample evidence, but it may suffice to state, that in many cases I have known it carried from places where the disease prevailed, to others in which no instance of it had previously occurred, and in the latter to become epidemic. From the repeated observation of this fact, I feel called upon to admit the accuracy of Cullen's definition, with the qualification of the term "contagious" being used synonymously with infectious. It is only necessary to add, that this affords farther proof of the "specific" nature of the disease, as a disease to be capable of propagation in such a manner, must have a specific character. In this respect, hooping cough follows the known laws of most diseases which prevail epidemically, and all of which, I believe, can and do occasionally assume the property of extension by infection.

The definition of the cough could not well be more accurate, as, brief as it is, when taken in connection with its generic position, it embraces all save one characteristic, viz., its occurrence in paroxysms, which will demand our especial notice hereafter. The term "convulsive" here may be taken as expressive of "spasmodic," and can therefore be subject to no objection; its "suffocative" character is equally unquestionable; whilst its being accompanied by sonorous and repeated loud inspirations, is the cause of the name "hooping" being given to the disease, and must therefore carry with it the assent of all. The last-mentioned phenomenon—"vomiting"—also demands particular attention, as it forms one of the main diagnostics of the disease, as will be presently shown. The only omission of consequence in the above otherwise very concise and truthful definition, is that of its occurrence in paroxysms, with an interval of health between them. When the above is compared with the symptoms of bronchial inflammation, we shall very readily perceive that the analogy is but remote, and that the disease under consideration, however frequently complicated with bronchitis, is essentially distinct from it. Another circumstance requiring notice is the occurrence of hooping cough but once in a life-time, whilst bronchitis may and does repeatedly attack the same individual, hooping cough also, for the most part, happening in the early years of infancy and childhood.

Let us now take a glance at the symptoms characteristic of inflammation of the mucous membrane lining the air passages, and then compare them with their concomitant physical signs,—with those met with in, and generally admitted as pathognomonic of, pertussis. Here again the definition given by Cullen, though under the term of catarrh, is sufficient to indicate the difference, which recent pathology confirms, as existing between the two diseases, as does also the position which he has given to it in his classification.

"Pyrexia sæpe contagiosa; muci ex glandulis membranæ narium, faucium, vel bronchiorum, excretio aucta; saltem hujus excretionis molimina."

Again, his division into species:—

Sp. 1. Catarrhus à frigore.

Sp. 2. Catarrhus à contagio.

Under the first of these may be included common or accidental attacks of bronchitis; whilst the latter, as obviously applies to what has now received the appellation of "Influenza." The above definition is somewhat imperfect as applied to bronchitis, as is also its position objectionable, as in it the primary stage of the disease, which is truly inflammatory, seems to have eluded observation, and the second only to have arrested attention. Without dwelling longer on the imperfections of such definition, I will, as briefly as possible, endeavour to make good the deficiency or error, and thereby indicate more clearly the difference between bronchitis and pertussis, merely observing that, like other inflammatory affections, bronchitis should have been placed under the head "Phelgmasia."

Bronchitis, like pneumonia, may, by careful observation, be very properly divided into stages, and it is in fact of the greatest importance to its successful treatment, more especially in infancy and childhood, to note such stages, as the therapeutic indications are seriously influenced by the pathological condition peculiar to them. In the commencement of an attack of bronchitis, the symptoms are the following, modified by the severity of the disease, and the extent of lung involved, as also by age and temperament, acceleration of breathing, with (in most cases,) pain on a full inspiration being made, which is also almost always productive of cough. The cough, which is generally present from the very commencement of the disease, in a greater or less degree, is at first dry, short, and hard, being unattended at this period by any expectoration; as the disease advances, expectoration of a frothy tenacious mucus takes place, which, as it becomes more free and easy, is accompanied by a very marked remission of all the symptoms. The cough throughout the whole course of bronchitis is *casual* in its occurrence, although repeated efforts are sometimes requisite to dislodge the mucus, when very viscid and tenacious. In an ordinary case of bronchial inflammation, the following are the physical signs:—

Percussion generally elicits a dull sound, which is regulated in extent by that of the portions of lung affected; thus it may be confined to a single lobe of one lung, or it may prevail over the whole of one or even both sides of the chest. When the stethoscope is applied in the early stage, we have the dry, sonorous, and subcrepitating rales in the affected parts, whilst in others, the respiratory sound will be so augmented as to claim the term "puerile." As the disease makes progress, the sonorous dry rale is lost, and we have in its stead the moist or mucous rale, this last being materially influenced in its character by the *tenacity* and quantity of the mucus, and also by the size of the tubes in which it is present.

The foregoing very brief and superficial notice of bronchitis has been given merely for the purpose of facilitating the comparison which must now be instituted between the two diseases, and for such end may prove sufficient. One other remark only is at present necessary, viz., these symptoms and physical signs, although they vary in duration and intensity according to the progress and duration of the disease, are continuous,—*i.e.*, unattended by any *real remission* or *interval of health*.

If we compare the symptoms of the two diseases, we shall readily, and by very unequivocal evidence, see that they are not only distinct in their nature, but also, on farther examination, find that they cannot co-exist. To such comparision I will now proceed:—

In bronchitis the fever corresponds with the extent and severity of the attack, and continues with little or no remission so long as the inflammatory action persists. The pulse is generally in a proportionate degree, accelerated and hard; the face is flushed; the eyes suffused; the cough is at first hard, dry, and though casual in its occurrence, distressing from its constancy; it is also seldom, if ever, terminated by vomiting; it finally becomes loose and less harsh, and is attended by expectoration; whilst the auscultatory sounds already described are always present, and gradually disappear as the inflammation subsides. Bronchitis occurs sporadically, and is peculiar to no period of life. Nor does the patient who has once suffered from it obtain any exemption from future attacks, but on the contrary rather acquires a greater tendency to it.

Hooping cough is generally met with during infancy and childhood. It seldom assails the same individual more than once in a lifetime. It most generally prevails in the epidemic form, and is capable of propagation by infection. The cough occurs in paroxysms, is spasmodic in its character, and is generally terminated by vomiting. Between the paroxysms there is an interval of apparent health, during which, even when the paroxysms are most distressing and violent, the patient makes no complaint. In a very large proportion of cases, percussion and the stethoscope afford no indications of disease, although in many cases there is more or less of the *mucous rale* audible, which of course is indicative of increased secretion into the bronchial tubes. This phenomenon deserves especial attention, as it may appear to indicate the presence of sub-acute bronchitis; it may, however, be explained independent of such condition, and therefore shown not in reality to militate against the view of the pathology of the disease which I am about to advocate.

What has now been said of the symptoms sufficiently indicates the difference between the symptoms and physical signs of the two diseases; hence, it is only necessary to take a brief glance at the pathological condition on which such difference depends, and which will be found to be important, not only in fact, but still more so as regards the successful treatment of either one or other. One prefatory remark may be made,

viz., that bronchitis very frequently supervenes on pertussis, or, in other words, becomes a complication of it, or, *vice versa;* this being made evident by bronchitis when the epidemic influence which generates pertussis prevails, terminating in the latter.

The pathology of bronchitis is now so universally understood, that it is superfluous to enter upon the *ratio symptomatum.* Not so, however, that of pertussis; wherefore, some little space must be devoted to the consideration of the phenomena met with in, and characteristic of, this very peculiar disease. The features which more especially call for notice are the following:—The character of the cough, its occurrence in paroxysms, and termination in vomiting; the interval of health between the paroxysms of coughing; the general absence of the physical signs invariably present in bronchitis. On each of these heads a few remarks may now be made, in order to demonstrate, by subsequent comparison, the real difference between *bronchitis* and *pertussis.*

First, the cough is spasmodic in character, occurs in paroxysms, and very generally terminates in vomiting. It has been well observed, that the violence and convulsive nature of the cough resembles that which arises from the presence of foreign bodies in the larynx; and that the larynx is very mainly implicated in its production, may be easily perceived by any one who will carefully observe the state of the child during the paroxysm, when, from the violent action of this organ and the contiguous muscles, it will be apparent that the chest itself is comparatively passive. The opposite is observable in cases of bronchitis, except where continued coughing is required to evacuate the viscid mucus, so commonly present in the earlier stage of the disease. The violence of the fits of coughing in pertussis forbids the idea of the existence of any continuous affection of the air-tubes as its cause; as, were such really the case, we should not only have serious febrile action, but also during the prevalence of such agency no interval of repose could by possibility have place. That the larynx is mainly concerned in pertussis, therefore, may be inferred; nor is this conjecture at all invalidated by the forcible and loud inspirations to which the "hoop," or "whoop," is properly attributed, such effort being physiologically requisite to compensate for the interruption which respiration sustains during a paroxysm. The termination of the cough by vomiting deserves especial attention, not only because it is a pretty constant occurrence in this disease, but also as tending to corroborate the view now taken of its pathology. In all probability this symptom has its origin in the participation of the stomach in the morbid condition already alluded to as affecting the larynx. Nor does the quantity of mucus discharged in this way in any degree militate against such supposition.

From these symptoms, together with the interval of comparative health, except where the case presents a complication with bronchial inflammation, I am led to consider the actual seat and nature of pertussis as essentially referrible to some morbid condition of the *pneumo-gastric nerve,* the influence of which over the organs of respiration and digestion is too well known to require comment.

The advocates of the inflammatory nature of hooping cough have laid considerable stress on the presence of the mucous rale during the intervals. If, however, the influence of the nerves generally, and of the *eighth* in particular, over secretion be considered, we shall in this sign even find corroboration of the nervous origin of the disease. This is farther supported by the immense quantity of mucus so frequently discharged from the stomach, to which fact is probably to be ascribed the notion of some of the older writers, that hooping cough was "*true catarrh of the stomach.*" From our still very imperfect knowledge of the nervous system, it would be little short of presumptuous in me, and most certainly idle, to enter into any speculations as to the real condition of the nerves in this disease; wherefore I will endeavour by a brief summary, to compare and point out the difference between this disease and inflammation of the air-tubes, premising that, with laryngeal or tracheal inflammation, it is impossible for any practical man for one moment to confound it.

Pertussis is essentially a disease peculiar to infancy and childhood. Bronchitis occurs indiscriminately at every period of life.

The cough in pertussis is spasmodic or convulsive, always occurs in paroxysms, and very frequently assumes a periodical type. In bronchitis it is casual in occurrence, however frequent and distressing, and rarely attended with vomiting, which is the common termination of the paroxysm in hooping cough.

In pertussis, the patient is comparatively well during the intervals; in bronchitis there is no *intermission,* although there may be some remission of symptoms.

Pertussis almost invariably occurs as an epidemic; bronchitis is of sporadic occurrence, but from any peculiarity in the atmosphere, or sudden vicissitudes in the weather, frequently prevails epidemically.

Hooping cough is unattended by fever; bronchitis in its mildest form, presents us with febrile disturbance. When fever is present in pertussis, it does not bear any proportion to the frequency or violence of the paroxysms; in bronchitis it corresponds with the extent and degree of the local affection.

The cough in bronchitis is unattended by the "whoop" to which pertussis owes its name, whilst in the latter, this pathognomonic symptom is lost, so soon as inflammation of the bronchial tubes actually sets in.

Finally, the treatment which alone is to be relied on in bronchitis, has little, if any, effect, either

in shortening the duration, or mitigating the severity of hooping cough.

The morbid appearances met with on examination of those who have died from this disease, may be supposed to favour the inflammatory doctrine, as in a large proportion of such cases bronchitis has been the cause of death; this, however, only confirms what has been already stated,—viz., that bronchitis frequently supervenes on pertussis. So far as my own experience extends, I would say that more fatal cases have been owing to the accession of cerebral than of pulmonary disease; the preponderance of the one or other appearing to be, in a very great measure ascribable to the progress made in the process of teething, during the operation of which a majority of fatal cases has been in consequence of the supervention of head symptoms, even when bronchial inflammation had been previously present. Thus, during one very general epidemic of hooping cough, in the treatment of which I was extensively engaged, about seventeen years ago, the most common fatal termination was either by convulsions or effusion into the cavities, and between the membranes of the brain.

From the length to which these remarks have extended, I must now be as brief as possible in regard to treatment. In hooping cough I have never seen any actual benefit result from depletion, except where active inflammation was in existence; on the contrary, positive injury appeared, in several instances, to follow its adoption. This observation applies both to the general and topical abstraction of blood, which seemed not only to exert no influence in diminishing the severity of the paroxysms, or curtailing the duration of the disease, but also to add to the already morbid sensibility of the system. Full emetics, repeatedly given, aided by alkalies, with cochineal, were, in the simple form of the disease, most efficacious; to which may be added, the internal and external employment of sedatives, as the hydrocyanic acid and the tincture of hyoscyamus internally, and friction of the spinal region of the chest, either with the soap liniment with opium, or camphorated oil, either of which I have found more useful than more stimulant embrocations. Of the emetics, ipecacuanha, alone, or in combination with small doses of the sulphate of zinc, has been preferred to antimonials. Where, in addition to the hooping cough, the patients suffered from bronchial irritation, the ipecacuanha wine, or the antimonial wine, was advantageously added to the alkaline mixture with cochineal. From papers which have been recently written on the utility of the carbonate of potass with cochineal, it may not be irrelevant to state, that such combination has been in use for a very long period, I having first met with it in a manuscript of formularies used by my late father, who copied it, when a young man, either in London or Edinburgh, and used it extensively in his practice. When the disease has persisted for some time, and circumstances permit, great benefit is derivable from change of air. During the earlier period, however, the observance of an uniform and rather warm temperature has the advantage of preventing the supervention of bronchitis, thereby materially lessening the danger of the disease, and also increasing the efficacy of other treatment.

CASE OF STRANGULATED FEMORAL HERNIA SUCCESSFULLY TREATED BY OPIUM.

By Charles Mayo, Esq., F.R.C.S., Surgeon to the County Hospital, Winchester.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

Not observing that any other correspondent has given you the result of his experience in the treatment of strangulated hernia, after the manner recommended by Dr. Butler Lane, in the *Provincial Journal* of the 21st ult., I beg to send you the following case, which seems to be strongly confirmatory of his views.

Mrs. D., aged 67, became subject to femoral hernia on the right side about four years ago, at which time it was strangulated, and after some trouble I succeeded in reducing it by the taxis. Since that time she had worn a truss, and was careful to keep it reduced. The truss had now become broken and nearly useless. After some unusual exertion on the morning of the 24th of April, she felt a large portion of bowel suddenly to protrude, she became sick, took opening pills, and laid up. On the 25th she sent to me; I found the swelling as large as an egg, painful, and tender, from her having used much exertion in endeavouring to reduce it, or push it back, as she said. She was constantly sick. I gave her a cathartic enema, and used the taxis without effect. I then left her six pills with a grain of opium in each, desiring her to take one every hour till I saw her again, beginning at four p.m. At nine o'clock I found that she had taken four of the pills, that the vomiting had ceased after the first, and that she was quite easy; cold cloths were kept applied to the swelling, which remained immovable. As she was so easy, I advised the two remaining pills to be taken at intervals of four hours, another glister to be thrown up in the course of the night, and a cathartic draught to be given at six in the morning.

April 26th. I received a message this morning that Mrs. D. was completely relieved, and on my calling about twelve o'clock, I found that the fifth pill was taken at midnight, and the sixth at four in the morning; after this she felt completely relaxed all over, her bowels rumbled about, and the swelling seemed to be enlarged and distended with wind, but soon after on feeling it with her hand, it had become softer, and presently went entirely up under very slight pressure. She took the draught at six, it had operated satisfactorily, and she was delighted to sleep all the day after.

I was not less pleased to have the necessity for an operation to be superseded, which I had the day before considered as nearly inevitable. Dr. Butler Lane has so well set forth the *modus operandi* of this remedy that I have nothing more to add, than that if you consider this communication to be of any use as an encouragement to others to make such trials, it is quite at your service.

I am, Sir,

Your obedient Servant,

CHARLES MAYO.

Winchester, May 26, 1847.

OPIUM IN STRANGULATED HERNIA.

[The following case, reported by Dr. Richard Long, of Arthurstown, appears in the *Dublin Medical Press* for May 12, 1847, and taken in connection with the preceding case, and those reported by Dr. Butler Lane, will probably interest our readers.]

On the 11th of January, 1847, I was called to Mrs. P., aged 47, whom I found suffering from intense pain in the lower part of the abdomen; thirst insatiable; incessant vomiting of a brown coffee-coloured fluid; pulse small, 110; extremities cold; countenance anxious and sunken; bowels constipated. This had been her state ever since the evening of the preceding day, now sixteen hours.

On examination I found a firm inelastic tumour, about the size of a large egg, in the right groin, not very painful to the touch; the abdomen was slightly swollen, and very tender. It appears that she has had an inguinal hernia for several years, for which a truss used to be worn, but this for some time past had been laid aside.

As it was evident the gut was strangulated, I had the woman placed in a warm bath and bled her, and then tried reduction of the protruded bowel by the taxis without effect; a tobacco enema was thrown up, and the taxis again tried ineffectually. As I was now obliged to leave my patient, an anodyne draught was given, a pill containing half a grain of opium, and one grain of calomel ordered every hour, effervescing draughts occasionally, pounded ice to be kept continually on the hernial tumour, and the bath to be again used during the night.

I was prevented from again seeing Mrs. P. until noon of the 12th, when I found her situation most alarming. The pulse was at 126, small and hard; countenance still more sunken, and of a leaden hue; vomiting incessant and stercoraceous; abdomen more swollen and tender; hernial tumour unaltered; occasional hiccough. A tobacco enema of full strength was thrown up, and the patient again placed in a warm bath. Whilst she was under the complete influence of the tobacco, every prudent effort at reduction was patiently, but ineffectually tried. The necessity of an operation seemed now inevitable, but the patient or her friends would not hear of it. I therefore, as a *dernier resort*, determined to try what opium in large doses would do.

A pill containing three grains of opium and two grains of calomel was directed to be given every hour, and an enema of strong chicken-broth thrown up every fifteen minutes, in order to support her failing strength. The three pills first given were speedily rejected; the fourth and fifth were retained; a cessation of pain and vomiting followed, and by the time that eight pills were given an urgent desire to evacuate the bowels followed the administration of one of the broth injections, which led to relief and perfect recovery.

[Cases of the successful employment of opium and its preparations in the treatment of strangulated hernia, have been reported also by Dr. A. W. Davis, of Presteign, (*Provincial Medical and Surgical Journal*, Aug. 28, 1841.) Dr. David Bell, of Carlisle, (*Monthly Journal of Medical Science*, Sept., 1841; *Braithwaite's Retrospect*, v. 4., p. 149.) Mr. George Cooper, of Greenwich, two cases, (*Medical Gazette*, Feb. 18, 1842.) Dr. James Ross, (*Monthly Journal of Medical Science*, Jan., 1843; *Braithwaite's Retrospect*, vol. 7., p. 239.) Mr. J. M. Walker, of Newcastle-on-Tyne, (*Medical Gazette*, Jan. 12, 1844.) Mr. J. W. Rowlands, of Ironbridge, (*Provincial Medical and Surgical Journal*, Feb. 5, 1845.—Ed.]

REPORT OF THE DISEASES AND MORTALITY OF ROMSEY, HANTS.

By Francis Buckell, Esq., M.R.C.S.

January to March, 1847.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

Sir,

I have forwarded the following tables for insertion in the Journal, as an accompaniment to the meteorological observations recorded at Romsey.

With regard to the tables themselves, I would just remark, that thay are not strictly comparable with each other, inasmuch as the Sick Register is drawn from the practices of but two out of five practitioners; whereas the deaths and births apply to the entire district.

The proportion of measles is higher than would ordinarily occur in general practice, as about thirty of the patients were inmates of the poor-house.

Amongst the deaths is one from hooping cough, whilst this disease is not found in the Sick Register, no cases having happened, either in my own or the parish practice; and I believe but very few in the district.

I shall refrain at present from any farther observations on the tables, as it can be only by a lengthened series of such records that striking or important results are to be expected.

I am, Sir,

Yours respectfully,

FRANCIS BUCKELL, M.R.C.S.

Romsey, May 15, 1847.

REMOVAL OF A SCIRRHOUS TUMOUR OF THE BREAST: INHALATION OF ÆTHER.

By W. M. Trousdale, Esq., West Butterwick.

Mrs. Barnard, of West Ferry, aged 62, of bilious temperament, mother of two children, first perceived a small tumour on the lower part of the right breast about two years ago. Lately it had increased much in size, and become painful. It presented all the characters of scirrhus, being hard, circumscribed, and moveable. The skin covering its surface was slightly adherent and puckered, but the nipple not retracted, nor the glands in the axilla affected. On May 8th, I operated for its removal, in the presence of Mr. Robert Eminson, of Scotter, and my assistants. The vapour of æther was previously administered from Bell's apparatus. The patient inhaled it seven minutes, when she became perfectly insensible. The excision of the tumour was then effected in about three minutes, by two elliptical incisions, of seven inches in length, including the nipple, and a greater portion of the breast, and two small arteries required to be tied.

During the operation the patient talked deliriously, and appeared quite unconscious of what was being done. On her return to consciousness, which took place in ten minutes, she was asked whether she had felt any pain, and replied, "Not the least: I know nothing about it." Whilst inhaling the æther, her pulse rose from 75 to 110, but soon after subsided to 90. She complained of headache and considerable stiffness of the muscles for a few days, but had no other unfavourable symptoms.

Hospital Reports.

LIVERPOOL NORTHERN HOSPITAL.

A report of the medical cases treated at the Northern Hospital, during the year terminating 31st December, 1846, was lately read to the Liverpool Medical Society, by Dr. Turnbull, one of the physicians to the hospital. The following is an abstract of the paper:—

At present the hospital contains 104 beds, but it can accommodate 180 patients, when the completion of the docks at the north end of the town will render increased accommodation necessary. The institution was originally intended chiefly for the reception of accidents, and acute or urgent medical cases; and though it has, since the new building was opened, assumed more the character of a general hospital, the medical, as well as the surgical cases, are still chiefly of the same severe description. The severity of the cases arises from the hospital being situated near to the most densely populated and unhealthy part of the town, and from being also close to the docks and shipping. From the latter it received many bad cases of scurvy, dysentery, pulmonary consumption, and various organic diseases, which, from their nature, or from not being attended to at sea, are peculiarly severe and fatal.

During the year 1846, the number of medical cases admitted was 731; of surgical, 889;—that is, 1620 patients treated in the hospital. To these must be added 94 remaining from the preceding year, and 789 out-patients, (chiefly slight accidents,) making in all 2503.

Of the 731 medical cases, there were 59 classed as febrile diseases; 29 of these were cases of intermittent fever in seamen, most of them from the United States, and from the coast of Africa. In this class there was but one fatal case.

Of rheumatic affections there were 149 cases, three of which were fatal.

Of diseases of the nervous system there were 66 cases, and five of them fatal; three died from apoplexy, one from hemiplegia, and one from intoxication with rum.

Of diseases of the respiratory organs, there were 152 cases, 29 of which proved fatal. Of the latter, 17 were cases of pulmonary consumption.

Of diseases of the organs of circulation and of the blood, there were 30 cases, and eight of them proved fatal. There was one death from purpura hæmorrhagica, two from scurvy, and five from disease of the heart.

Of diseases of the stomach and intestinal canal, there were 155 cases; and of these, 20 were fatal. There were 105 cases of diarrhœa and dysentery, 16 of which died.

Of diseases of the liver, there were 21 cases, two of which were fatal.

Of dropsy, there were 33 cases, six of which died.

Of diseases of the urinary organs, there were five cases; of uterine diseases, ten; of secondary syphilis and skin diseases, 39; of diseases of the eye, four; and eight cases of other diseases not classified, including one fatal case of inflammation of the air passages from the fumes of nitrous acid.

The rate of mortality in 1846 was higher than usual. The total number of cases treated in the hospital, excluding those remaining from the preceding year, and out-patients, was 1620, and the deaths, 135, or one in 12; 731 were medical cases, of which 74 died, or one in $9\frac{7}{8}$. From comparing this with a table for the year 1843, I find that the mortality was above the average, 42 deaths having occurred in that year in 507 medical cases, or one in $12\frac{1}{4}$. That the mortality should have been higher than usual, does not, however, seem surprising, when we find, from the reports of the Registrar General, that it was much above the average over the whole kingdom, (50,000 in England and Wales above the average in 1846,) chiefly owing to the prevalence of diarrhœa and dysentery. In the Northern Hospital these diseases proved fatal in sixteen cases, thus standing next to pulmonary consumption, which was the cause of death in seventeen.

It should, however, be observed, that a higher rate of mortality might at all times be looked for in this hospital than in most others, owing to the ordinary state of health of the population from which it receives many of its inmates, and the severe nature of the cases. The annual mortality of the whole population of Liverpool is about one in 28; so that it would seem that the deaths among the medical cases during their period of sickness in the hospital was three times greater than among the whole population annually. The recent extensive emigration from Ireland, which

has brought many thousands of poor famished creatures, either already in a state of disease, or highly predisposed to fever and dysentery, has clearly shown that this high rate does not arise solely from unhealthiness of the town itself—of its resident population. From this debilitated class of persons, however, and from other non-resident classes—sailors and foreigners, a considerable number of our patients are furnished. The severe and urgent nature of the cases is also such, that it not unfrequently happens that patients are brought to us in *articulo mortis*, while others, who have just landed from ships, and have been long ill, survive but a few days.

PROVINCIAL
Medical & Surgical Journal.
WEDNESDAY, JUNE 16, 1847.

We have received a copy of an Address from the Honorary Medical Board of the Liverpool Workhouse and Fever Hospital, to the ratepayers of the parish of Liverpool, which is fraught with matter of such immediate importance to the best interests of the public, that we deem it our duty to lose no time in bringing the subject to which it refers before the members of our widely extended Association. The town of Liverpool has been placed in an unfortunate position, by the immigration of so large a number of our suffering fellow-countrymen from Ireland, bringing with them as they did, not only the call for large pecuniary assistance, on account of their starving condition, but also the seeds of fatal disease, which has but too rapidly communicated itself to, and carried its ravages among, the native population. The great increase of fever cases appears to have led to increased demands for hospital accommodation by the district surgeons, for those who were the sufferers under it; and the parochial authorities, after a long period of indifference, were induced at last to take some steps to meet the evil, the growth of which has, no doubt, been greatly augmented by the want of earlier attention in this respect.

Under these circumstances it seems that "the Medical Board of the Workhouse was in the middle of February last," we quote the words of the address, "for the *first* time consulted, in the form of a call to sanction the appropriation of a part of the Workhouse, then occupied by the infirm and aged men, to the purposes of a fever-ward." The over-crowded state of the house very properly operated with the Medical Board in inducing them to refuse to sanction the introduction of fever-cases into the infirmary of the institution, or the appropriation of a ward as a fever-hospital, it appearing on an investigation, that there was "scarcely a ward in the house, for the reception of either healthy or sick, in which there were not twice as many persons as there ought to be, and that there were many in which there were four times the number."

The address goes on to show that, "at the time that this statement was made, the average cubic dimensions allowed for each of 601 persons, and his bed, was only 300 cubic feet, and that of this number, each of 289 had only 233 cubic feet, and that each of the remaining 312 had an average of 363 cubic feet. In other words, 601 persons slept in less than one-third, 289 of them in less than one-fourth, and 312 in little more than one-third of the space deemed necessary by the Commissioners of Prisons for the preservation of the health of the inmates of a gaol.

An arrangement was afterwards proposed, and cordially assented to by the Medical Board, by which "the whole of the Infirmary looking towards Brownlow Hill" was to be cleared out, for the reception of fever-patients; the medical, surgical, and lying-in patients, to be removed to wards selected by the Board in a new building.

In direct contravention of this arrangement, the Workhouse Committee removed a part of the inmates—the infirm and aged to cells "little better than under-ground cellars;" and the medical, surgical, and lying-in patients were "carried off in the dead of the night to the old nurseries, which had been disapproved of as wards by the Board, where they were found next morning, by the physician and surgeon in attendance, huddled together, in some cases two in a bed, and without any provision for their comfort, at a time when a very fatal epidemic of dysentery prevailed." The consequences may readily be anticipated. "On the 17th of April it was represented that thirty-seven men slept in eight beds, and ninety-six women and children in thirty-eight beds, and that eight cases of fever were removed to the fever-wards the next morning. On the 24th of April, twenty-one cases at least of fever were removed from different parts of the house to the ward in one day; fourteen deaths in the course of the week had taken place from fever and dysentery in the cleansing wards: a deputation from the Board on this day found twenty cases of fever in these wards, a general prevalence of severe dysentery, and, in one instance, three cases of fever in one bed."

It is unnecessary here to pursue the subject farther, excepting to state, that in the collision which necessarily took place between the Medical Board and the Workhouse Committee, and

subsequent investigation before an Assistant Poor-Law Commisioner, that functionary took part with the Committee; when, after a fruitless application to the Poor-Law Commission, the Medical Board feeling their efficiency to be at an end, with the utterly inadequate means placed at their disposal to enable them to discharge their duties properly, have withdrawn themselves from all responsibility, and from the charge of the hospital.

This cannot but be regarded under existing circumstances, as a public calamity to the town of Liverpool, and it is greatly to be feared the inhabitants will suffer *en masse* by this ill-judged parsimony, for we presume that the item of expense is at the root of the conduct of the Committee in thus opposing themselves to the wise precautionary recommendations of the Medical Board. With the contagious and fatal fever which exists in, or threatens, not only Liverpool, but most of the larger towns in the western districts, and from the same cause, it is earnestly to be hoped that every attention will be paid to those sanatory precautions, and especially the avoiding of over-crowding in Union Workhouses and other public establishments, which the knowledge and experience of the medical profession enable them to point out. The very trifling cost to the public, almost indeed inappreciable, at which the services of the medical profession are obtained in the charge of the sick poor, should at least facilitate the employment of all fitting arrangements for preventing the spread of contagious disease.

The greater part of the public and private medical charities throughout the kingdom, it is justly observed, are worked by Honorary Medical Officers. How the Union officers are remunerated may be learned from the subjoined extract:—"In the rich town of Liverpool, now proverbial for the amount of disease existing in it, the whole remuneration for skilled medical relief, under ordinary circumstances, exclusive of that afforded by the private charities, is less than £1600 per annum, being little more than one halfpenny in the pound of the annual value of the rateable property, and from £1120 of this, paid to sixteen district surgeons, is to be deducted the amount expended in supplying the pauper population with medicine."

We beg to direct attention to the announcement made in the last number, and repeated in another column of the present number, on the subject of the Council Prize. From the subscriptions and donations made to the Council Fund since its establishment at the last Anniversary at Norwich, the Committee there appointed to manage this fund have been enabled to offer the sum of fifty pounds as a prize for the best Essay or Report "On the Cerebral Affections of Infancy." Other subjects have been under consideration, and it is hoped that the fund for the succeeding year will be so far augmented, as to allow not only of some of these being proposed for competition, but at the same time of subjects of original research being named for investigation, and other measures being brought forward for the advancement of medical science.

Reviews.

A System of Surgery. By J. M. Chelius, Doctor in Medicine and Surgery, &c., &c. Translated from the German, and accompanied with additional Notes and Observations. By John F. South, late Professor of Surgery to the Royal College of Surgeons of England, and one of the Surgeons to St. Thomas's Hospital. London: 1847. 8vo. 2 vols. pp. clxvii., 814 and 1009.

We have great pleasure in announcing the completion of this truly important work, and it is no small credit, both to the translator and the publisher, that the promises of regularity of appearance made at its commencement have been fulfilled to the letter. Many works published in a similar manner, but far less elaborate, and with little excuse for failure in this respect, still linger in the hands of author or printer, the earlier numbers of which, already becoming obsolete, long preceded the appearance of the first instalment of the work before us, and it is with regret we learn that the publisher (if not the author,) is likely to be deprived, by the very merits of the work, in an extensive field at least, of the fair reward of his rare and commendable perseverance.

Any review of so comprehensive a work, in the limited space which we are able to devote to noticing the publications of the day, is out of the question; we are compelled, therefore, to a very brief exposition of its contents, with a general expression of approbation of the manner in which Mr. South has executed the translation, and an acknowledgment of the greatly increased value which the original work of Professor Chelius derives from the numerous comments in this edition. So numerous indeed are these, and so important to the elucidation of the subject treated upon, to its general literature and practical utility, that it cannot but be observed, that the "System," in its English dress, is as much the work of Mr. Smith as of its German author.

The "System of Surgery" of Chelius and South, as it may be justly termed, is arranged under eight sections or divisions. The first of these is devoted to the subject of inflammation; the second treats of diseases which result from the disturbance of physical continuity;

the third, of diseases dependent on unnatural coherence; the fourth, of those dependent on the presence of foreign bodies; the fifth, of diseases which consist in the degeneration of organic parts, or in the production of new structure; the sixth treats of loss of organic parts; the seventh, of superfluity of organic parts; and the eighth, and last, of the elementary proceedings of surgical operations. The first two divisions occupy nearly the whole of the first volume; the other six form the contents of the second volume.

We shall not stop to inquire into the merits of this arrangement, whether it is the best which might have been constructed, or whether in the following of it out, the several subjects succeed each other, in a natural or convenient sequence. The treatise is essentially a work of reference and consultation for the advanced practitioner, rather than a guide-book for the mere student; and any deviation from the various systems of arrangement which different individuals may prefer is more than compensated by the very copious analytical index, extending to nearly one hundred and eighty closely-printed pages. This index adds greatly, in our opinion, to the value of the work, as it enables those, with whom time is an object, at once to obtain an epitome of what is to be found in the body of the work, or any subject on which information may be looked for.

The Surgeon's Vade Mecum. By Robert Druitt, Fellow of the Royal College of Surgeons. Fourth Edition. London. 1847. Fcp. 8vo, pp. 620. With numerous wood-cuts.

The merits of this work are so well known and so justly appreciated, as to render it unnecessary to do more than briefly announce the appearance of another edition. It is, however, right to mention, that much new matter of interest to the surgeon has been added, chiefly in the practical parts of the work. Among these may be enumerated the sections on inflammation; on malignant diseases; the treatment of aneurism by compression; the section on diseases of the ear; and some very useful directions on bandaging, accompanied by illustrations. The number of the illustrations throughout is also very much increased, and, notwithstanding the acknowledged excellence of the preceding editions, the present will be found considerably to surpass them.

Proceedings of Societies.

SHROPSHIRE AND NORTH WALES BRANCH OF THE PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

ANNUAL MEETING.

The Annual Meeting of the Shropshire and North Wales Branch of the Provincial Medical and Surgical Association, and of the resident medical practitioners of Shropshire, was held on Friday, at Shrewsbury, May 28th, and was well attended by members of the profession from Oswestry, Wellington, and other towns.

P. Cartwright, Esq., of Oswestry, the President of the Branch Association, on taking the chair, observed, that in exerting himself to ensure a numerous meeting on that occasion, he had been influenced solely by the desire he felt, as President of the Association, to make himself useful to the profession. He thought advantage should be taken of the Parliamentary Committee now sitting on Mr. Wakley's Medical Registration Bill, to make the members of the legislature better acquainted with the wants and wishes of medical men, and something would, no doubt, result for their benefit. It was only necessary, in his opinion, that they should now come forward and make their grievances known, to gain all that was essential to the prosperity and usefulness of the profession, and raise its members in the estimation of society. By the Registration Bill a line of circumvallation would be drawn around the educated practitioner, broad and distinct, so as to separate the quack from those who possessed legal qualifications. He regretted to state that illegal practitioners too often received aid from those of the profession who ought not to encourage them. Mr. Wakley's bill was not, perhaps, all that could be desired, but that gentleman had done his best to simplify the measure, and adapt it to the present exigencies of the profession. He thought it was, at all events, sound in principle, and claimed the support of every member of the profession; and it also appeared to him that there were many points that would contribute to the protection and well-being of the profession.

In the present anomalous state of the profession, the general practitioner was excluded from the College of Physicians, and insulted by the Council of the College of Surgeons, and the profession, as a body, was left unprotected, and stripped of that collegiate and social standing which they had legally acquired at great trouble and expense. The Council had exercised the powers of their new charter invidiously, and the persons selected for the fellowship had no more claim to that distinction, on the score of merit, than the thousands on the college list who were passed over. If the selection had been confined to hospital and infirmary surgeons, and the right to elect the Council had not been granted to the fellows, he did not know that there would have been so much to complain of, but he thought they had a right to complain, when individuals were elevated to the rank of fellows to the great disparagement of others equally worthy of the title. The petition he should have the honour to lay before them would, he believed, embody their sentiments on the subject of the Registration Bill, and the more important subject of medical and surgical education, and he hoped their exertions might aid its being carried through Parliament.

The following resolutions were then adopted:—

1st.—Proposed by S. Wood, Esq., seconded by R. P. Weston, Esq.

"That the Medical Registration Bill, in forming a

legal distinction between those who are properly qualified to practice medicine and surgery, and those who are not so qualified, and in affording a legal recognition and sanction to practice to the qualified practitioner, is sound in principle, and deserving of the support of the Profession."

2nd.—Proposed by M. WEBB, Esq., seconded by R. BROUGHTON, Esq.

"That it is incumbent upon the legislature to provide, by every means in their power, for the suppression of *quackery*, by which the public are grossly imposed upon, and many valuable lives annually lost."

3rd.—Proposed by W. EDDOWES, Esq., seconded by T. PIDDUCK, Esq.

"That it is essential to the best interests of the Medical Profession, that one uniform standard of conjoint medical and surgical education, combined with practical examinations, be established, as a test of capability for practice for all those who shall hereafter enter the profession under any title whatsoever."

4th.—Proposed by J. DICKIN, Esq., seconded by Dr. DRURY.

"That the numerous corporate bodies having the power of granting degrees ought to be assimilated in the amount of qualification required for the attainment of each degreee of a like denomination, and that the Medical Registration Bill will be highly beneficial in effecting this object."

5th.—Proposed by E. BENNION, Esq., seconded by J. R. HUMPHREYS, Esq.

"That it is of the greatest importance to place before the Parliamentary Committee, appointed to enquire into the laws that govern the Profession, the evils that result from the irresponsible power possessed by the corporate bodies, more particularly the Colleges of Physicians and Surgeons, and to endeavour to obtain for the great body of the members of those colleges a just and fair system of representation therein."

6th.—Proposed by Dr. FULLER, seconded by SAMUEL WOOD, Esq.

"That the following petition be presented to Parliament in accordance with the views of this meeting:"—

To the Honourable the Commons of Great Britain and Ireland in Parliament assembled.

The Petition of the President and Council of the Shropshire and North Wales Branch of the Provincial Medical and Surgical Association, and of the resident Medical and Surgical Practitioners of Shropshire, in public meeting assembled,

Sheweth,—

"That your petitioners beg respectfully to impress their gratitude for the consideration you have evinced towards the medical profession by the appointment of a Committee to investigate the subject of medical registration and of the state of the law relating to the practice of medicine and surgery in these kingdoms.

"That your petitioners are of opinion that the grievances which affect the medical profession arise from the following causes:—

"1st. That ignorant and unqualified persons have the power of assuming, with impunity, professional titles and degrees, and thereby grossly and injuriously imposing on the public.

"2nd. That no uniform standard of conjoint medical and surgical education exists, and that divers colleges and bodies corporate have the privilege of granting degrees and titles at rates of education and qualification essentially differing from each other.

"3rd. That the Colleges of Physicians and Surgeons hold an irresponsible power, which, in the instance of the College of Surgeons, under their recent charter, has been arbitrarily and injuriously exercised towards its members.

"4th. That the Apothecaries' Company is the only body corporate capable of granting a licence to practise in England and Wales, and may thus interfere to prevent those from practising who possess higher qualifications than the members of that body.

"Your petitioners, therefore, considering it essential to the health and safety of the public, as well as to the improvement of the profession, that these grievances be redressed, entreat your Honourable House,—

"1st. That the Medical Registration Bill be passed into a Law.

"2nd. That one uniform and determinate standard of conjoint Medical and Surgical Education, combined with two or more practical examinations be established, and that no person after the passing of the Medical Registration Bill, be registered, or entitled to practise, who cannot produce testimonials of having completed such conjoint education and examination, excepting always those in actual practice at the time of the passing of such Bill, and qualified to be registered under it.

"3rd. That a just and fair system of *representation* be accorded to the great body of the members of the profession in their several Colleges, and, in particular, that the irresponsible power now possessed by the Colleges of Physicians and Surgeons, be so modified on the representative system, as to impart to those institutions a greater influence, security, and efficiency,

"And your petitioners will ever pray."

7th.—Proposed by W. HOWLETT, Esq., seconded by Dr. WILLIAMS.

"That the members of the county and the different boroughs therein be requested to support the Medical Registration Bill."

8th.—Proposed by Dr. DRURY, seconded by R. BROUGHTON, Esq.

"That the thanks of this meeting be given to PEPLOE CARTWRIGHT, Esq., for his impartial conduct in the chair, and for the unwearied energy with which he has, upon all occasions, exerted himself to promote the interests of the Medical Profession."

At the conclusion of the meeting the members and visitors adjourned to the dinner table, where, on the removal of the cloth, the healths of the various officers of the Association were proposed from the chair, which was ably filled by Mr. Cartwright; and the question of Medical Reform made the subject of extended comment and discussion by several gentlemen present. Altogether

the anniversary was both more numerously attended, and more gratifying in its results, than any similar meeting held in Shrewsbury for some years.

T. J. Drury, M.D., Physician to the Salop Infirmary, was elected President for the ensuing year.

BATH PATHOLOGICAL SOCIETY.

Fourth Meeting, Jan. 4th, 1847.

Mr. NORMAN in the Chair.

CASE XIV.—*Habitual palpitation of the heart; dyspnœa; distinct bruit, heard most clearly at the lower part of the sternum. Dissection:—Dilatation of the right side of the heart; diseased tricuspid valves.*

Mr. Waldron related the history of a case, with an account of the *post-mortem* appearances; the specimens could not be obtained. The patient, a woman about 63 years of age, first came under Mr. Waldron's care about eight or ten months previous to her death, at which time he learned that she had been much subject to palpitation of the heart from an early period of life. On examination there did not seem any enlargement of the left side of the chest; the action of the heart was irregular, and she complained of dyspnœa, which was increased by any exertion, palpitation at the same time being induced; the heart's action was accompanied by a bruit, heard most distinctly at the lower part of the sternum; there was also a thrilling sensation communicated to the hand when placed over the region of the heart; the pulse at the wrist was feeble and became intermittent on slight exertion. Her symptoms for a time appeared to yield to treatment, but after exposure to cold and over-exertion she was attacked with syncope and died without rallying. The body was examined forty-eight hours after death; the heart was found much enlarged, softened, and of a yellowish grey colour; the right cavities contained a considerable quantity of fluid blood; the right auricle was much enlarged; the tricuspid valves at their base were contracted and cartilaginous.

CASE XV.—*Acute tuberculization of the lungs; death in twenty-one days from first symptoms.*

Mr. Field exhibited portions of both lungs taken from the body of a girl, 15 years of age; her history is as follows:—Until within a week of the time Mr. Field first saw her, which was twelve days before her death, she had enjoyed tolerably good health, though never robust; she had never suffered under any pectoral symptoms, neither cough, short breathing, nor pain of chest. She had never menstruated. On examination she complained of slight pain under the sternum and in the region of the heart; percussion elicited an unsatisfactory sound beneath both clavicles, and beneath the right there was slight crepitation; the respiration was rather hurried, and the expansion of the chest imperfect; her pulse was quick and weak; no expectoration; her general appearance was that of a person labouring under serious disease, which, combined with the physical signs, led Mr. Field to consider the case as one of acute tuberculization. The last six days of her life she was very feeble. On dissection, both lungs were found minutely studded with miliary tubercles, all of small and uniform size. The specific gravity of both lungs was so much increased that they sank rapidly in water, and shewed but little tendency to float in a saturated solution of alum and nitre; there was slight thickening of the mitral valve, though not sufficient to render it incompetent for its office; the liver was enlarged and fatty; the brain and kidneys were not examined. The period within which the disease proved fatal was as nearly as could be ascertained twenty-one days. Mr. Field remarked on this case as illustrating a form of disease, rapidly and apparently certainly fatal, and alluded to similar cases that have been placed on record by Louis, especially one case, where the duration of the disease was as nearly as possible the same. Mr. Field then alluded to the question as one of much interest,—whether this acute form of tuberculization was to be considered as an effect of inflammatory action or not? and gave as one reason against such a view, that in acute tuberculization both lungs are almost invariably affected, whilst double pneumonia is comparatively rare.

CASE XVI.—*No history. Dissection:—Adherent pericardium.*

Mr. Bush exhibited a heart taken from the body of a man, about 70 years of age. Concerning his previous history there was not much known, except that he had suffered from a severe attack of what was called asthma, about six years before. On dissection, the pericardium was found very much thickened and adherent throughout; the heart was much enlarged, and the aorta more capacious than natural; the endocardium was healthy, and the valves sound; a portion of the pleural covering the right lung was adherent to the pericardium.

CASE XVII.—*No history. Sudden death. Dissection:—Rupture of the aorta.*

Mr. Hunt exhibited part of the arch of the aorta of a man, concerning whom he had no history, except that death had taken place rather suddenly. The portion of the aorta was much dilated, and presented a longitudinal (as regards the course of the vessel,) rupture of the internal coat; and at some distance from the seat of injury of the inner coat, was an irregular opening in the aorta through which the blood had escaped.

CASE XVIII.—*No peculiar nervous symptoms; sudden death. Dissection:—Calcareous deposit in the nervous matter of the cerebellum, and also in the arteries of the brain.*

Mr. Skinner exhibited a portion of the cerebellum of a middle-aged woman, in whom there had not appeared any peculiar symptoms referrible to the nervous system; death took place suddenly and unexpectedly. On dissection, the brain was found much congested; the arteries exhibited extensive calcareous deposit; the portion of the cerebellum shown was so loaded with calcareous deposit that there remained little appearance of nervous matter, except the form.

CASE XIX.—*Apoplexy, insensibility, complete paralysis of the left side. Dissection:—Effusion of blood into the right lateral ventricle; calcareous deposit in the arteries at the base of the brain.*

Mr. Norman exhibited the brain of a man, 75 years of age, who had suffered about six years before his death from what seemed an apoplectic fit; he recovered perfectly, but has since been subject to occasional threatenings of a similar nature, which, in more than one instance, seemed to have been warded off by depletion. On Friday, the 1st of January, he had an attack similar to the first, followed by almost complete insensibility and perfect paralysis of the left side; he remained in this condition about forty-eight hours, when he died. On dissection there was found a large clot of coagulated blood, occupying chiefly the right lateral ventricle, the pressure of which, against the roof of the ventricle, had given rise to the appearance of softening; but on making a section into the nervous matter, such did not seem to have been the case. Some blood had found its way into the left lateral ventricle, but not into any of the other cavities of the brain. The precise source of the hæmorrhage did not appear. The arteries at the base of the brain were much diseased, especially the basilar, which was merely a rigid tube from the deposition of calcareous matter.

CASE XX.—*Chronic rheumatism; some degree of lividity of countenance; physical signs of obstruction of the left side of the heart, with hypertrophy: sudden death. Dissection:—Aneurism of the left ventricle.*

Dr. Davies exhibited a heart taken from the body of a young man, 21 years of age, who was admitted into the hospital suffering under chronic rheumatism. It appeared that about three months before his admission he had had an attack of acute rheumatism, for which he had not received any medical advice. He had no recollection of having suffered from pain in the region of the heart, but thought that lately he had been less able to exert himself than formerly. On examination, the countenance appeared rather livid and anxious; respiration quick and shallow; the pulse was small, frequent, and gave a thrilling sensation to the finger. His position in bed was on the back, with the shoulders raised. Percussion over the region of the heart gave a dull sound over a larger space than natural, whilst the impulse of the heart was attended by a general heaving of the left side of the chest.; the second sound of the heart was obscured by a distinct but not very loud bruit. The respiratory murmur in both lungs was feeble. A few ounces of blood were taken from the arm, which did not separate well into clot and serum, but formed a dark-coloured diffluent mass, much resembling blood drawn in typhus fever. His symptoms underwent no change during the four days he was in the hospital, when, on rising from his bed he fell suddenly back, and died within an hour. On dissection, eighteen hours after death, the heart was found much enlarged; the pericardium universally adherent, and greatly thickened. On laying open the left ventricle, there was found, immediately within the left aortic valve, an aneurismal sac, about the size of half a walnut; the other two valves were thickened and contracted; the aneurismal sac was filled with partially decolourized lymph and coagulated blood, the lymph being external. The endocardium around the aneurism was covered with thin layers of lymph, and at one point distinct from the aneurism, there was a small ulcerated opening through that membrane. On opening the left auricle, there was found a patch of lymph, exactly opposite the aneurism, showing where rupture would have occurred, had not death prevented such an event; the wall between the two cavities was at this point very thin. The right cavities did not present anything uncommon; the lungs were much congested, otherwise healthy; the liver and spleen were enlarged, the former weighed six pounds ten ounces; the brain was congested, and the blood fluid, so that several ounces flowed out whilst dissecting that organ.

Dr. Davies remarked on this case as being one of by no means frequent occurrence, and as furnishing a clear example of aneurism of the left ventricle, arising from inflammation of the endocardium, terminating in ulceration and rupture of that membrane, and probably softening of the muscular tissue beneath, and thus, by means of the successive impulses of the blood, permitting a cavity to be hollowed out in the muscular structure of the wall of the heart.

TOTAL ABSTINENCE, AND MEDICAL TESTIMONY.

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOURNAL.

SIR,

Nothing could be farther from my intention, than to excite the angry feelings of your intelligent correspondent θ, by any apparently harsh observations on the important subject of his letter: I intended no such thing; and much regret that θ should imagine for one moment such to be the *animus* of my expressions. The cause of truth needs no such vulgar an attendant as anger, and I leave all irritation,—all suspicion of offence, to the steady defenders of an established error. I am content, if my observations should elicit thought on this momentous subject; and although a considerable number of observing and experienced physicians and surgeons differ *toto cælo* from my opinions, yet that is *no reason* for their incorrectness.

I need not remind your correspondent, that all new opinions which make breaches in the citadel of our established habits, must of *necessity* be adopted slowly; and I only wonder that the principles of the four disputed propositions have been so largely sanctioned and adopted—a pretty sure proof of their correctness, and that in time they will be generally believed.

I quite agree with θ, in his right of investigating and judging for himself in this matter, but he must also grant me the permission to put his opinion in one scale, and the recorded views of the eminent men before-mentioned in the other scale, and then we shall see whether the *argumentum ad verecundiam*, whose support, he says, my cause appears to need, does not apply to himself, and his position: perhaps, indeed, θ belongs to that class described by Cicero as "*Homo timidus virginali verecundia.*"

I must beg to correct a statement in reference to my having characterized your correspondent's *observations* as absurd and ludicrous; but the gist of my statement was, that the *position of a nameless individual* was absurd; or in other words, that there was something of the ludicrous in a nameless individual attacking the deliberate opinions of some half dozen distinguished men; and to this view I still adhere. θ is too acute an observer not to see that a man's position may be weak, while his opinions may be very well expressed, although ever so erroneous.

It would require a volume to receive the evidence in favour of the truth of what θ says is *unproved*, and every man's experience, I believe, would afford him abundant testimony in favour of the fact "that a very large portion of human misery, including poverty, disease, and crime, is induced by the use of alcoholic or fermented liquors as beverages." I rejoice, however, that θ "freely grants" there are persons to whom total abstinence is both on physical and moral grounds desirable, and I surmise that after all we are perhaps only differing in degree rather than in principle. I am no advocate for *universal* pledging, but I know, in many cases, the pledge is the only security for a man. It is only the other week I sent a patient (a medical man,) to an asylum, who, had he taken the pledge some time since, would in all probability have been now at his daily duties; but no, he would not pledge himself, because he thought the *use*, and not the *abuse*, of a little stimulus, could do him no harm. I must again request θ to read Liebig's tenth letter before referred to, as evidence that beer and spirits are not elements of nutrition, and therefore do not promote the formation of blood; neither are they even *necessary* elements of respiration, else how would all the tribes of animals exist? They drink not but at Nature's stream. The North-American Indian, before he saw the white man, lived long, and was happy, but the demon of ardent spirits came, and poisoned him by thousands. I trust the equanimity of your correspondent will not be disturbed by any of my observations; if it be I must really throw down my pen in despair, and believe that a delusion has hold of his mind, which nothing short of teetotalism will remove.

In conclusion let me say that in discussing this subject controversial strife should be avoided, and as I am anxious that the profession should lead the public mind, I beg my brethren to consider the statements made, and judge for themselves.

I remain,

Yours respectfully,

EDWARD HUMPAGE.

Bristol, June 4, 1847.

P.S. I do not reply to Dr. Robertson's remarks, written as they are in an excellent spirit, because in the first place they were not addressed to me; and, moreover, his objections are in part answered in this correspondence.

INJURIOUS EFFECTS OF THE INHALATION OF ÆTHER.

[The following observations on the injurious effects of the inhalation of æther, are extracted from a letter lately published by Dr. James H. Pickford, of Brighton.]

The blood, robbed by the æther of its oxygen, impoverished by the solution by the same agent of myriads of corpuscles, of those especially with which it comes into immediate contact, depreciated as a consequence, in the quantity and deteriorated in the quality of its fibrin, intensely blackened by the solution of its corpuscles and their contained hæmato-globulin, is chemically deprived to a considerable extent of its powers of coagulation and rendered unfit for the purposes of life. A black vitiated blood circulates through the system, analogous in many particulars to that in putrid and malignant fevers.

This impaired condition of the blood is not even partially corrected until respiration of atmospheric air has been permitted for some considerable time, and until lymph corpuscles have found their way into the circulation to replace those of the blood destroyed by the æther. Many persons, especially those who are out of health or enfeebled by long previous disease, are hours, days, nay weeks, recovering from the state induced by the inhalation; many die from its direct effects,—from the want of oxygenized and vitalized blood to stimulate healthfully the brain and nervous system.

With a view to counteract some of the ill consequences of ætherization, it has been proposed that the patient should inhale oxygen gas, "as *an antidote*." This, of necessity, presupposes the exhibition of a *poison*. So that a patient about to undergo operation is to inhale a poison, be subjected to its deleterious effects, and then to swallow an antidote, as though the operation were not of itself sufficient, without all this extra complication of poison and antidotes, suspended animation or actual death, proximate or remote.

But what are the facts? Ætherized blood cannot be reddened by oxygen gas, simply because its black red colour is not dependant alone on a chemical change in the hæmatin. The æther has also dissolved the blood-corpuscles, and thus permitted the escape of the contained hæmato-globulin; and these it cannot restore. Had the blood been merely rendered artificially venous by the absorption of its oxygen, or by cutting off its ordinary supply, its arterial colour would be restored by agitating it with oxygen. In the following experiment, these facts are pretty clearly established.

In each of two vessels I caught eight and a half ounces, by weight, of arterial blood; both vessels were instantly plunged in water at a temperature of 98° Fahrenheit. The blood in one vessel was exposed for three minutes to the influence of the vapour of æther. The blood became of an intensely black red colour, whilst coagulation was to a very considerable extent interrupted. Subsequently, oxygen gas was diffused through the ætherized blood; but no restoration of colour could be produced. Placed in the field of a powerful microscope, numerous flocculi, the remains of the capsules of the corpuscles, were observed floating in the fluid portion of the blood, which was rich with these remains. At the

expiration of 72 hours, the blood in both vessels was weighed—that which had been subjected to the vapour of æther yielded *five and a half* ounces of black red *fluid*, and three ounces of a stringy *clot*, conclusive evidence of the small amount of fibrin. The fluid portion of the blood (serum) in the other vessel, in which neither flocculi nor corpuscles could be detected under the microscope, weighed *half* an ounce, the *clot*, *eight ounces*.

This indisposition of the blood to coagulate after the inhalation of æther offers another very serious consideration. Fatal hæmorrhages must occur, and do occur; and as the whole circulating fluid is deteriorated by the æther, is it matter of surprise that the lips of wounds evert, that the discharge is unhealthy, that stumps become flabby or gangrenous, and that patients sink and die?

Ætherization, it is to be feared, exerts also a baneful influence directly upon the respiratory organs. A medical friend in Dublin informed me recently that of thirty fatal cases following operations in which æther had been employed in the various hospitals of that city, eight were found to be the subjects of recent tubercles of the lungs, the undoubted product, it was believed, of inhalation.

The endeavour to alleviate human suffering under one of the most trying of all situations, the knife of the surgeon, is highly praiseworthy, and the public must feel deeply indebted to those medical gentlemen who have devoted their time and talents in the attempt to achieve so desirable an end. It becomes us, however, to ascertain, as far as we are able, whether the means employed are compatible with the health and lives of those about to undergo operations.

Pain during operations is, in the majority of cases, even desirable; its prevention or annihilation is, for the most part, hazardous to the patient. In the lying-in chamber nothing is more true than this: pain is the mother's safety, its absence her destruction. Yet are there those bold enough to administer the vapour of æther even at this critical juncture, forgetting it has been ordered that "in sorrow shall she bring forth."—*Brighton Guardian*, June 2nd.

General Retrospect.

ANATOMY.

VULVO-VAGINAL GLAND.

M. Huguier has given a description of a gland situated at each side of the junction of the vulva to the vagina. It was discovered by Gaspard Bartholin, and was generally described by older anatomists; but of late its existence has been almost forgotten. According to M. Huguier, this gland is about the size and form of an apricot kernel, and is provided with an excretory duct, about seven or eight lines in length, the external aperture of which is situated in the angle between the vulva and the border of the hymen. This gland is small until puberty, when it is developed with the other organs of generation; it becomes turgid during sexual excitement, and secretes a quantity of clear mucus-looking fluid, which it is said to ejaculate with some force. M. Huguier agrees with former anatomists in regarding this gland as closely analogous to Cowper's gland in the male subject, for it is situated in about the same part of the perineum as this latter is, and presents the same anatomical relations and connexions. It is an appendage to the vulvo-vaginal cavity, a part which is analogous to the urethra in the male; it receives the materials for its nutrition and its sensation from the same vascular and nervous sources as does Cowper's gland; it presents also many varieties in form, size, and situation, and it may be absent on one or both sides, as is often the case with Cowper's gland.—*Archives d'Anatomie.*

PHYSIOLOGY.

INFLUENCE OF THE PNEUMOGASTRIC NERVES ON DIGESTION.

The results of some experiments performed by MM. Bouchardat and Sandras, to determine the influence possessed by the pneumogastric nerve over digestion, shew clearly that division of both these nerves in the neck, at once arrests the process of digestion so far as the stomach is concerned, but has no influence over that part of the process which takes place in the intestines. After feeding dogs with a mixed diet, and then dividing both pneumogastric nerves, they found, after twenty-four hours, that those substances, the digestion of which is effected principally in the stomach, such as albumen and fibrin, were quite unchanged, whereas those substances which are digested in the intestines, such as the amylaceous and fatty principles, had been dissolved and absorbed just as though the pneumogastric nerves had been undivided. In several of these experiments they found that, although no chyme is prepared in the stomach after division of the nerves, yet the starchy principles which pass into the intestine are there converted into glucose, and that the fatty matters are absorbed by the lacteals, just as in the ordinary state of health; so that the digestion and disposal of these principles appear to be quite uninfluenced by the operation. They found also that it is not by compression of the trachea, by the distended œsophagus, that rabbits die when fed after division of the pneumogastric nerves as high up as on a level with the larynx.—*Comptes Rendus*, Jan., 1847.—*Medical Gazette*, April, 1847.

ON THE FOOD OF CHILDREN.

By Dr. Thompson.

[After some remarks on the relative quantities of nutritive matter in various articles of diet, Dr. Thompson makes the following useful observations on the appropriate food of children.]

"Milk, in some form or other, is the true food of children, and the use of arrow-root, or any members of the starch class, where the relation of the nutritive to the calorifiant matter is 1 to 26, instead of being as 1 to 2, by an animal placed in the circumstances of a human infant, is opposed to the principles unfolded in the preceding table. In making this statement, I find that there are certain misapprehensions into which medical men are apt to be led at the first view of the subject. To render it clearer, let us recal to mind what the arrow-root class of diet consists of. Arrow-root and tapioca are prepared by washing the roots of

certain plants until all the matter soluble in water is removed. Now, as albumen is soluble in water, this form of nutritive matter must in a great measure be washed away; under this aspect we might view the original root before it was subject to the washing process, to approximate in its composition to that of flour. If the latter substance were washed by repeated additions of water, the nitrogenous or nutritive ingredients would be separated from the starchy or calorifiant elements, being partly soluble in water, and partly mechanically removed. Arrow-root may therefore be considered as flour deprived as much as possible of its nutritive matter. When we administer arrow-root to a child it is equivalent to washing all the nutritive matter out of bread, flour, or oatmeal, and supplying it with starch; or it is the same thing approximatively as if we gave it starch; and this is in fact what is done, when children are fed upon what is sold in the shops under the title of "Farinaceous Food,"—empirical preparations of which no one can understand the composition without analysis. Of the bad effects produced in children by the use of these most exceptionable mixtures, I have had abundant opportunities of forming an opinion, and I am inclined to infer that many of the irregularities of the bowels, the production of wind, &c., in children, are often attributable to the use of such unnatural species of food. It should be remembered that all starchy food deprived of nutritive matter is of artificial production, and scarcely if ever, exists in nature in an isolated form. The administration of the arrow-root class is therefore only admissible when a sufficient amount of nutritive matter has previously been introduced into the digestive organs, or when it is inadvisable to supply nutrition to the system, as in cases of inflammatory action. In such cases the animal heat must be kept up, and for this purpose, calorifiant food alone is necessary. This treatment is equivalent to removing blood from the system, since the wasting of the fibrinous tissues goes on, while an adequate reparation is not sustained by the introduction of nutritive food. A certain amount of muscular sustentation is still, however, effected by the arrow-root diet; since, according to the preceding tables, it contains about one third as much nutritive matter as some wheat flours. The extensive use of *oatmeal*, which is attended with such wholesome consequences among the children of all ranks in Scotland, is, however, an important fact, deserving serious consideration, and it appears to me, is strongly corroborative of the principles which I have endeavoured to lay down.—*Experimental Researches on the Food of Animals*, 1846, p. 169—171.

PATHOLOGICAL CHEMISTRY.

CHEMISTRY OF THE BLOOD.

In a work which is noticed in the *Monthly Journal* for May, 1847, Professor Haeser has analysed the hæmatological investigations of Andral, Becquerel, Rodier, and others, and considers the following aphorisms warranted by his results:—

1. The average composition of the healthy blood is probably the following—22, fibrin; 131 blood-corpuscles; 70, albumen; 6.8, salts; 210, solid matters generally; 790 water.

2. The most general effect produced by acute diseases upon the blood consists in the diminution of its solid matters in general, and especially of its blood-corpuscles. The only exception to this rule is to be found during the first stage of typhus, scarlatina, and measles. Whilst the blood-corpuscles appear thus diminished, the solid residue of the serum, especially the albumen, is to be met with in greater amount; the same is the case with respect to the fibrin.

3. During the progress of acute diseases, the blood-corpuscles become yet more diminished, and simultaneously the solid matter of the serum is also undergoing diminution; it is only the fibrin that is sometimes increasing, even during the progress of genuine inflammatory diseases, whilst it is also diminished in the "pyrexiæ." The same effect as occurs in advanced disease, can generally be produced by blood-letting.

4. Concerning the special character of the true inflammatory processes, we meet with the following characteristic alterations of the blood—Diminution of the alkaline salts, moderate increase of albumen, and a considerable one of fibrin. Besides this, there appears an incorporation between fibrin and albumen, and a direct one between the former and water.

5. Pneumonia is chiefly characterized by a great amount of fibrin; pleuritis, by that of albumen; bronchitis, by a comparatively slight alteration in the composition of the blood.

6. In acute articular rheumatism, the blood differs from that in genuine inflammations only by the greater diminution of blood-corpuscles, and the corresponding abnormal amount of the solid residue of the serum, and of the water. Another particularity of the rheumatic blood is the normal quantity of the salts, and the steadiness of the amount of fibrin.

7. In the fever accompanying the pyrexiæ, we do not recognize any constant alteration, either in the solids or in the blood, capable of explaining their essential character—(Andral.) In typhus fever we observe the following alterations—Till the eighth day of the affection the blood-corpuscles, together with the albumen, and in consequence of these, the solid matters generally, are in undue amount; after that time a progressive diminution of all the solid substances takes place, occurring in the blood-corpuscles most, and the fibrin least. On the twenty-first day the general increase of the solid materials returns again. One or two blood-lettings, made during the first eight days, produce but a slight influence upon the composition of the blood; whilst at a later period the blood-corpuscles are thereby very considerably diminished.

8. Acute articular rheumatism, simple erysipelas, and puerperal peritonitis, considered as to the composition of the blood, form a group which differs from inflammation as well as from typhus fever, by the considerable quantity of water, serous residue, and fibrin induced, and by the extraordinary diminution of the blood-corpuscles. The analogy between the three diseases just mentioned becomes still more obvious on considering the exudations in them, the water and albumen of which, compared with the composition of the blood, are much increased. At a later period, and

after blood-lettings, puerperal peritonitis approaches very nearly to typhus fever.

9. Variola, scarlatina, and rubeola, constitute also a natural group, so far as the composition of the blood is concerned. To the two last-named diseases the undue amount of solid matters in general at their commencement, and the constant increase of albumen and alkaline salts, seem to be characteristic. Hence these diseases approach on the one hand to the erysipelatous, and on the other to the typhus, composition of the blood.—*Ueber den Gegenwartigen Standpunkt der Pathologischen Chemie des Blutes.*

SOURCE OF FALLACY IN TESTING THE URINE FOR SUGAR.

Dr. Rees has pointed out the fact, that the dark colour produced by boiling the suspected urine with caustic potash (Moore's test,) is not satisfactory, unless the purity of the potash be first ascertained. He was led to this knowledge by having failed to detect sugar in a specimen of urine said to be diabetic, when it occurred to him that the dark colour met with by the party sending the urine might be due to the presence of lead in his potash, which was found to be the fact by testing it with hydro-sulphuret of ammonia.—*Medical Gazette*, April 2nd.

[This hint is valuable, and as far as our recollection goes, original, on the part of Dr. Rees.]

SURGERY.

RESULTS OF THE OPERATION FOR STRANGULATED HERNIA.

In the hospital practice of MM. Boyer and Manec, since the year 1833, fifty-eight operations for strangulated hernia have been performed, the results of which are interesting, as regards the propriety of employing the *taxis*. Thirty of these cases were operated upon by M. Boyer. From 1834 to 1839 M. Boyer did not proceed to the operation till prolonged attempts at reduction had been made; during this period *nine* cases were operated upon, of which *eight* died and *one* recovered. From 1839 to 1843 he employed the taxis to a much more limited extent; *seven* cases were submitted to operation, of which *four* died and *three* recovered. From 1843 to 1846, he had almost entirely abandoned the use of the taxis, and out of fourteen cases on which he operated, *four* died and *ten* recovered. M. Manec, on the contrary, during the same time, placed little reliance on the taxis, and uniformly proceeded almost at once to the performance of the operation. The results of this practice were, that of *twenty-eight* cases operated on, *two* died and *twenty-six* recovered.

The practical deduction to be drawn from these statistics is, that the employment of the taxis is productive of much harm. No statement, however, is made as to the results of the cases which were successfully treated by the taxis. To judge fairly of the good or evil resulting from the attempts at reduction, the entire number of cases of strangulated hernia admitted into the hospitals should be given, and we doubt not that in such an aggregate of cases, the number of recoveries would be greater where the taxis is moderately and judiciously applied, than where the operation is uniformly at once performed.

The conclusions drawn by MM. Boyer and Manec are, that the operation for hernia, performed at an early period, and before symptoms of peritonitis have declared themselves, is almost free from danger; and, 2nd, that peritonitis never occurs subsequently to the operation, if it has not been present previous to its performance.—*Revue Medico-Chirurg.*, Fevr., 1847; and *Monthly Journal of Medical Science*, May, 1847.

CURE OF NÆVUS.

In flat nævi up to the size of a crown-piece, lint steeped in pure liquor plumbi is fastened over the part with a bandage, and wetted by fresh applications of the lead, without frequent removal. After days or weeks, the swelling becomes whiter, flatter, and firmer; soon afterwards, little, firm, white spots form on the surface, and the cure is certain. By means of a solution of alum and compression, nævi so large that extirpation would have been impossible have also been curred. It may be necessary to keep the remedy constantly applied for six months.—*Dieffenbach's Operative Surgery*, and *Half-Yearly Abstract*, Vol. IV.

MIDWIFERY.

ON THE NATURAL PERIODS OF DELIVERY.

Dr. Leroy has observed the following circumstance in connection with the period of delivery:—1st, the natural term of delivery, as well as premature delivery, has a certain connection with the monthly periods; 2dly, the return of these periods during the whole duration of pregnancy agrees with the period of the month corresponding with the date of the day on which the catamenia commenced to appear for the last time, whatever may be the number of days reckoned to each month; 3dly, the premonitory symptoms of delivery at the natural period commence, in the majority of females, at the date mentioned, or during the succeeding seven days; 4thly, nevertheless, the commencement of the expulsive pains may still occur in the normal manner, at the fifteenth day of the tenth month; 5thly, every delivery which occurs before the date mentioned may be considered to be accelerated; 6thly, every delivery which occurs after that date may be considered to be retarded; 7thly, the accelerations are proportionably much less numerous than the protractions; most commonly they do not precede the time specified by more than five days; 8thly, the protractions, on the contrary, are not limited by any period; 9thly, in either case the causes of the accelerations and protractions are very appreciable in the greater number of instances.—*Journal de Loire*, in *Monthly Journal of Medical Science*, July, 1846.

ANECDOTES OF THE MEDICAL PROFESSION.

(*Continued from page* 196.)

IV. Our own times furnish me with a striking example of the deference paid to a physician by the highest potentates. When Dr. Jenner first promulgated the protective influence of vaccination against the danger of small-pox, the King of Spain fitted out an expedition

to carry the vaccine matter to every part of his transmarine dominions, and after having left the valuable material at the Canary Islands, the Caraccas, and all the provinces of South America, the director of the expedition resolved to carry the preservative to the remotest parts of Asia, and having stopped at Acapulco and the Philippine Islands, he introduced vaccination into China. The Emperor of Russia, too, after he had established the practice of vaccination throughout all his European dominions, sent Dr. Boutaltz to traverse his Asiatic possessions for the same benevolent purpose. The mission, therefore, when it had reached the capital of Siberia, proceeded to Ochotsk; from whence he sent it to Kamtschatka, and the islands situated between Asia and America. Fresh matter was transmitted also into China, so that the Spanish and Russian expeditions reached different points of the celestial empire nearly at the same time.

In the Island of Java, certain portions of land have been set apart for the support of vaccination, and as a mark of respect and veneration for the author of this valuable discovery, these lands have been designated, Jennerian lands.

This detail may be considered perhaps as affording evidence rather of the confidence of these Sovereigns in the merit of the new invaluable resource, than of their personal respect and deference to Dr. Jenner. But it is true that Bonaparte, in the plenitude of his power, accorded their freedom from bondage to no less than nine captives, severally, at the request of Dr. Jenner, a homage to the benevolent author of so important a discovery, and that the Emperor of Austria and the King of Spain, paid equal attention to Dr. Jenner's intercession in behalf of individuals who were detained in their dominions.—*Some Results of successful Practice of Physic, by Sir H. Halford. Essays*, p. 317.

V. There are few of our readers but must remember the melancholy impression, made on the public mind by the disastrous result of the expedition to the Niger, when this was made known in England through the newspapers. And none who remember this can forget that pathetic passage in the story, which represented the noble conduct of the surgeon, and the geologist of the expedition, when left alone in the far recesses of the Niger, amid their heroic companions, all stricken to death, or to death-like helplessness, by the fatal fever of the country. In this trying conjuncture, when the salvation of all on board depended on the speedy removal of the ship from her actual position, Dr. M'William took the navigation on himself, steering with his own hand, and piloting the vessel through all the intricacies of the river, while his companion worked the engine below. There is something very affecting, we had almost said sublime, in the picture thus presented to the imagination, of these two solitary men of science, assuming offices so foreign to their past habits and knowledge, stripped of all exterior cognizance of their class, standing as humble workmen at the helm and furnace, toiling by day, watching by night, while the force of the stream and the paddles was sweeping their ill-fated bark, freighted with their dying or dead companions, through the manifold dangers of their unknown course. The author of the volume before us was the clear-headed and stout-hearted pilot who did this, the undoubted preserver of the ship and her surviving crew, and the slight and simple way in which he speaks of his own exertions strikingly illustrates the old truth, that the brave man is ever modest. —*British and Foreign Medical Review*, vol. 16. p. 260.

VI. Sir Astley Cooper was kind enough to make us acquainted with his researches on the structure and functions of the thymus gland, with which he was then occupied; and I am the more pleased to recall this circumstance, because it enables me to record a reply of Sir Astley's, which proves delightfully the perfect truth and honesty with which he conducts his researches and experiments. While he was pointing out to us, on a most delicate preparation, the two membranes which he has found in what he calls the reservoirs of the thymus, I said to him, "You said, and it is." "No," he replied, "It is, and I said." The scientific character of the great English surgeon breathes in this response.—*Six Mois de Sejour en Angleterre par S. Pironde, D. M.—British and Foreign Medical Review*, vol. 8, p. 534.

VII.—When Dr. Dimsdale inoculated Catherine the Second for the small-pox, that Princess (who, whatever might be the vices of her moral character, possessed a very enlarged and magnanimous mind,) took precautions for securing his personal safety in case of her death. Finding herself much indisposed on a particular day, she sent for Dimsdale, whom she had already remunerated in a manner becoming so great a sovereign. "I experience," said she, "certain sensations which render me apprehensive for my life. My subjects would, I fear, hold you accountable for any accident that might befall me. I have therefore stationed a yacht in the Gulf of Finland, on board of which you will embark, as soon as I am no more, and whose commander, in consequence of my orders, will convey you out of all danger." This anecdote, so honourable to the Empress, I heard from one of Dimsdale's sons, above forty years ago.—*Sir N. W. Wraxall's Posthumous Memoirs of his own Times*, vol. 3, p. 199.

DR. SHEARMAN'S INTERPRETATION OF "THE MEDICAL REGISTRATION BILL."

TO THE EDITOR OF THE PROVINCIAL MEDICAL AND SURGICAL JOUNAL.

SIR,

Dr. Shearman, of Rotherham, has taken upon himself the office of interpreter of the Registration Bill, for the benefit of your readers, and he professes to foresee, not only how it will "come out from the Committee," but also how it will "work" in practice.

Dr. Shearman may be more competent than the Council of the Institute, as a body, but his letter in the Journal of May 19th, instead of proving his superiority, appears to me to reproach and abuse them by his misrepresentations; for he says in his first four reasons, that "the intended legalization of medical

men, (not qualified for general practice according to the present law,) by the Council, and by Mr. Wakley's bill, are the same in effect;" whereas, Dr. Shearman knows as well as they do (because they have so often told him,) that the Council would legalize such medical men *in the first instance only*, to prevent retrospective legislation. The doctor's fifth "reason" is equally incorrect.

Dr. Shearman, moreover, informs your readers "what the profession have a wish to demand," but does not tell us how he acquired a greater stock of information on that point than that which the Council have collected. Dr. Shearman knows which class of disputants "think rightly" on the subject, and leaves us to presume physicians, inasmuch as "he is a physician," and "he thinks rightly.

"There is nothing like leather."

Taking the whole tenor of Dr. Shearman's letter, *I suppose* he means to say, "that in the nineteenth century, general practitioners, instead of advancing, should have a retrograde movement in acquiring their general and medical education, and in the extent of their efficiency for performing the duties which they undertake." I may therefore be allowed to ask Dr. Shearman, whether he writes for the benefit of the physicians, or for that of the public?

Remaining, Sir,

Yours very truly,

W. ALLISON.

East Retford, May, 1847.

Medical Intelligence.

MEDICAL APPOINTMENTS.

M. le Baron Pasquier has been appointed Surgeon to the King of the French, in the room of his father, the late Baron Pasquier, and M. Alphonse Pasquier succeeds as Surgeon in Ordinary.

The following gentlemen have been elected officers of the Royal College of Surgeons of Ireland, for the ensuing year:—President, J. W. Cusack, Esq.; Vice-President, Robert Harrison, Esq.; Secretary, Alex. Read, Esq. *Council*—Sir P. Crampton; Messrs R. Carmichael, Wilmot, Read, Auchinleck, Kerin, Jacob, Tagert, Beatty, Hargrave, Ellis, Williams, Armstrong, Trant, Rynd, Adams, Barker. W. Colles, and Power.

ROYAL COLLEGE OF SURGEONS.

Gentlemen admitted Members on Friday, June 4th, 1847:—R. D. Larke; H. Fisher; T. Thompson; J. P. Bowling; E. Davies; J. H. Perry; F. H. Ransom; C. Oakeley; W. Ellery; C. Irving.

Gentlemen admitted Members on Friday, June 11th, 1847:—E. Alsop; J. P. Berryman; J. H. Cook, S. O. Habershon; J. L. Oldham; C. Pates; P. C. W. Cooke; P. Eade; V. de Meric; J. Wilson; P. Brady.

SOCIETY OF APOTHECARIES.

Gentlemen admitted Licentiates, Thursday, May 27, 1847:—Charles Sproull, Deasyhill; Edward Dawson Allinson; Wm. Henry Paine, Stroud; Henry Hides, Wisbeach; Alex. Mundell Champnes, Slough; Edwin Younge, Walesby; Francis Henry Blaxall, Claydon, Ipswich; Henry Heath Corbould, London; Henry Stevens; Thomas Hobson, Kinkella.

Thursday, June 3rd:—George Roper, Colby; Wm. Elleray, Bolton le Sands; Mark Hazelwood Clayton, Stratford-on-Avon; Robert Higginson, Yorkshire; John Bourne, Barnard Castle; Charles Wankford Currie, Bungay; Wm. Denton Dibb, Hull; Robert Muriel, Ely; Squire Sprigg, Bury St. Edmunds; George Housman Macnamara, Uxbridge; Henry Slade, R.N.; George Bruce, London.

OBITUARY.

Died, May 21st, at Ballinrobe, of typhus fever, John Roycroft, M.D.

May 22nd, aged 67, at Boulogne sur Mer, Dougal Campbell, M.D., Surgeon on half-pay of the Royal Artillery. Dr. Campbell was a claimant of the Earldoms of Annandale and Hartfell.

June 2nd, at Warrington, of fever, Wm. Morley, Esq., resident Surgeon to the Warrington Dispensary.

June 11th, at Liverpool, of typhus fever, John Whitley, Esq., Surgeon to one of the Union Districts.

BOOKS RECEIVED.

A Treatise on the Structure, Diseases, and Injuries of the Blood-Vessels, &c. Being the Essay to which the Jacksonian Prize for the year 1844 was awarded by the College of Surgeons of England. By Edwards Crisp, M.R.C.S., &c. &c. London: Churchill. 1847. 8vo. pp. 354. Plates.

PROVINCIAL MEDICAL AND SURGICAL ASSOCIATION.

COUNCIL PRIZE.

The Committee appointed at Norwich for the management of the Council Fund for the present year beg to announce that THE COUNCIL PRIZE of £50 will be given for the best Report "On the Cerebral Affections of Infancy."

The prize is open to general competition; the papers to be sent in to the Secretary of the Committee, Dr. Streeten, Worcester, on or before the 31st of May, 1848, each paper to have a motto affixed, and to be accompanied by a sealed envelope, bearing the same motto, and inclosing the name of the author.

NOTICE TO MEMBERS.

Gentlemen who have not yet paid their subscriptions for the current year, or who are in arrears, are requested to forward the amount due, either to the Secretary of the District in which they reside, or to the Treasurer or Secretary of the Association.

ROBERT J. N. STREETEN, Secretary.

BATH PATHOLOGICAL SOCIETY.

At the last meeting of this Society, held June 7th, it was resolved that the Society should adjourn until the first Monday in October.

ERRATUM.

At page 209, col. 1, line 13 from the top, for "the right pair being injured," read "the eighth pair, &c."

METEOROLOGICAL JOURNALS FOR APRIL, 1847.

Kept at Sidmouth, by W. H. CULLEN, M.D.; at Honiton, by Mr. ROGERS; at Romsey, Hants by FRANCIS BUCKELL, Esq., Surgeon.

MEDICAL & SURGICAL JOURNAL.

A COURSE OF LECTURES ON CLINICAL MEDICINE.

By W. R. Basham, M.D., Physician to the Westminster Hospital.

Lecture XI.

Acute Rheumatism, with metastasis to the Heart.—Pericardial and endocardial disease; general character of the physical signs; affections of the mitral valve distinguished from those of the aortic.—Progress of the case; the treatment; sudden death.—Post-mortem *examination.—Pathological conditions calculated to have brought about abrupt dissolution.—Treatment, when commenced after cardiac disease fully formed, less effective than when applied in the earliest stage.—Necessity for constant vigilance for heart-disease in acute rheumatism.*

Gentlemen,—The subject to which I am anxious to direct your attention to day is one of powerful interest in a pathological view,—pericarditis and endocarditis accompanying acute rheumatism,—the ravages of inflammation attacking the heart externally and internally. You have just left the *post-mortem* examination, and have witnessed the destructive effects of endocardial and exocardial inflammation. We will first examine the more prominent symptoms during life from the ward book, that you may the better understand the auscultatory signs of these destructive ravages; now that you can compare the cardiac disorganization with the altered murmurs you heard during life, you will also the better comprehend the fatal progress of such cases, and the principles that should guide you in their treatment.

E. S———, a girl of 14, form well developed, rich auburn hair, and of wax-like complexion, was admitted on February 17th, having been suffering from acute rheumatism in all the principal joints for the last seven days. On the second day after the joints were attacked she suffered acute pain in the præcordia, with fluttering sensation, and feelings of suffocation, short dry cough, and hurried respiration. These symptoms are stated to have daily become aggravated till admission. There was synovial effusion in both knee-joints, with great tenderness on pressure, and acute pain on motion; the knuckles of both hands were red, tumid, hot, and painful; the skin was of a feverish heat; the external surface extremely pallid, even exsangueous looking; the bowels had been freely purged; the countenance was anxious; the pulse 140, soft and full, no hardness; the heart's impulse was much augmented, tumultuous; great tenderness at the præcordia, shrinking from the slightest pressure; the heart's sounds were muffled, and there was general præcordial dulness; there was a prolonged systolic murmur heard most distinctly at the apex of the heart, diminishing towards its base, and scarcely heard at the upper part of the sternum. These auscultatory murmurs were sufficiently intelligible to declare that the progress of inflammatory action had already affected the mitral valve, the prolonged murmur heard most distinctly at the apex of the heart accompanying the systole being distinctly referrible to a mechanical imperfection of the valve.

I have had occasion more than once during the present session to point out to you the means of distinguishing affections of the mitral, from similar conditions of the aortic, valves. An error in the organic integrity of either produces a murmur coincident with the systolic sound; but when the mitral valve is affected, this murmur is heard most distinctly towards the apex of the heart, and towards the left. When the aortic valves are the seat of disease, the murmur is heard chiefly over them, and at the base of the heart, and continues to be heard distinctly, even up into the carotids; and, with imperfection in the aortic valves, regurgitation would take place during the diastole, and the second sound would also be accompanied by a regurgitating murmur. In this case, at this period, we only had evidence of disease of the mitral valve within the heart. The increased impulse and tumultuous action indicated that the pericardium was involved, and that in all probability, from the extensive præcordial dulness, the sac of the pericardium was filled with fluid, or was probably adherent to the heart. As the cardiac affection had existed for five days before admission, the rubbing murmur, which is usually present when the pericardium is first affected, had disappeared, either from the sac becoming filled with fluid, or the two surfaces becoming united by exuded lymph.

There could be no mistake as to the disease we were here called on to heal: there was no difficulty in the diagnosis; the signs manifested to the ear were explicit enough; and had the case come under treatment at an earlier stage, much might doubtless have been done towards saving life. At first I had no reason to doubt, that severe as the symptoms were, they might be made to succumb to remedies. The further history of the case will illustrate the amount

of influence they exercised. The character of the pulse, soft, without any sensation of hardness or wiryness in it, together with the wax-like exsangueous aspect of the surface of the body, under any circumstances, would have forbidden venesection; and in the young, in acute rheumatism, I am very averse to bleeding from the arm. She was directed to be cupped to ten ounces, as near the region of the heart as possible; and that we might, if practicable, bring her quickly under the influence of mercury. Hydrarg. Chloridi, gr. iii., cum Pulv. Ipecac. Co., gr. v., were ordered every four hours, the bowels to be relieved with a purging draught in the morning, and she was ordered to be placed in a warm bath.

On the next day we found the symptoms materially relieved; the pain in the præcordium had disappeared; the impulse of the heart had much diminished, and its tumultuous action had subsided; the rheumatic inflammation in the hands and knees had also abated. The sounds of the heart were more distinct, and now, in addition to the systolic murmur heard the day before, there was one accompanying the second sound, and prolonged after it, and heard most distinctly just over the aorta, and still heard as the stethoscope was placed higher and higher towards the top of the sternum. Here was the ordinary evidence of disorganization of the aorta in addition to the mischief already noticed in the mitral valve. As the bowels were much relaxed and the pulse kept up, but still soft, two grains of calomel, half a grain of opium, and a quarter of a grain of the potassio-tartrate of antimony were given, in the form of pill, every four hours.

During the next two days she improved very much, the pulse going down to 100, and the heart's action continued quiet, with the same physical signs, yet without any indication of ptyalism. On the 22nd the symptoms became again aggravated, rheumatic pains recurring in all the limbs. The heart's impulse again much increased; dulness over the entire præcordial region and to a considerable extent around it; physical signs as before; respiration hurried, 40; breathing much oppressed at times; tongue red, inclined to become dry, moist at sides; urine clear; remedies continued. On the 24th, after having taken two grains of calomel every four hours for six days, faint signs of ptyalism presented themselves; the tongue became moister; the paroxysms of pain in the chest intermitted; the urine became loaded with lithates; the heart's action subsided, and she felt considerably relieved. The mercury was continued in smaller doses, and a blister was directed to be applied all over the præcordial region. On the 25th, the pulse rose rapidly, and with it an increase in the heart's impulse; a sharp paroxysm of pain in the region of the heart, with a recurrence of the opppressed breathing, indicated the necessity for a further topical bleeding. She was cupped from the side to eight ounces.

On the 26th, the report states that a great improvement took place after the last cupping; the pain had entirely subsided; she breathed quietly, 26 per minute; slept a little; heart's sounds appeared clearer, less muffled; but the other physical signs remained unchanged, and there was still the regurgitating murmur after the diastole. On the 28th, a very visible improvement is recorded,—no pains, no dyspnœa, can move freely in bed, and has had some refreshing sleep; tongue moist; pulse 96, soft; heart's impulse not increased; signs as before. The amount of ptyalism produced was yet faint, and it being most desirable to obtain the full effect of mercury, a grain of calomel and half a grain of opium were continued night and morning. On the 1st of March a recurrence of a paroxysm of pain in the region of the heart and an attack of almost suffocative dyspnœa, spoke intelligibly enough of the continuance of unsubdued inflammatory action, and as the calomel, so constantly administered, had failed to produce full salivation, mercurial inunction was about to be employed, but was counter-ordered on the second, as the gums manifested increased mercurial action. All the symptoms on this day underwent a palpable improvement; the pulse was quiet and soft; the tongue moist; the gums exhibited the puffiness and tenderness of salivation. On the morning of the third, she is reported to have passed a very good night, sleeping some hours; the pulse is stated as 90; respiration quiet; all external indications of rheumatic inflammation subsided; the tongue moist; countenance placid; and some craving for food. She sat up in bed at twelve at noon, and was eating her diet of rice pudding; she laid her plate down suddenly, inspired deeply and gaspingly two or three times, and expired.

So sudden a death after the aspects of improvement and hope which the last twenty-four hours had presented was remarkable. Let us see if the *post-mortem* examination will throw any light on the pathological cause of this unexpected dissolution.

Sectio cadaveris twenty-five hours after death.—The external aspect of the body presented the appearance of a wax model; no sanguineous gravitation or purpling of the dependent parts, but the whole surface pale white, almost of alabaster purity. The cavity of the chest presented no diseased conditions. The lungs were of a pale flesh tint; the grey mottling but faint; no pleuritic adhesions. The mucous membrane of the larynx and trachea was pale and healthy; some fine capillary injection of the bronchial tubes in the secondary sub-divisions becoming darker in the smaller tubes, with the presence of some frothy white mucus. The heart and pericardium were firmly glued together by an uniform layer of gelatinous lymph; the two, with some degree of force, were separated and detached. At the base of the heart this jelly-like exudation was deposited in much quantity. The heart was generally enlarged; the walls of the left ventricle firm, and its cavity completely empty; not a vestige of either fluid blood, or clot, could be found in it. The mitral valve was much disorganized; the edge or rim of the valve much thickened, studded with wart-like excrescences, forming an unyielding irregular patent ring, when viewed from the auricle; the left auricle contained a very small clot of blood. Two of the aortic valves were transparent and perfect, but one was pouched, and had an excrescence of lymph deposited on it; one isolated patch of white cartilaginous deposit was noticed in the aortic arch. The right auricle and

ventricle were healthy, but much distended by large coagula. The viscera of the abdomen were healthy; the brain presented no conditions of disease.

The first question you will naturally ask after witnessing this examination is, what is the pathological condition that can explain the remarkable suddenness of the death? Could the defective valvular structures be the cause of this instantaneous death? Not of themselves alone. Could the adhesion of the pericardium to the heart, with the large amount of lymph deposited at the base of the heart, produce instantaneous death? Certainly not; for quite as large an amount of endocardial and exocardial disorganization has been recorded in other cases, where the termination of the disease has been slow, tedious, lingering,—dropsical accumulations or pulmonary congestions at length putting an end to the patient's sufferings. Could the endocardial and exocardial conditions conjointly bring about this abrupt decease? I think they could; and the emptiness of the left ventricle conveys a hint how this *death-stroke* may have been produced conjointly by these morbid causes. To comprehend the full force of these conditions, we must not overlook the effect of pericardial disease upon the heart's movements,—that in pericarditis the heart's action becomes irregular,—its impulse increased,—its motions tumultuous; in fine, that when lymph becomes deposited about the heart, its actions become embarrassed, irritable, and unsteady. With a heart adhering to the pericardium, and surrounded by recently exuded lymph, can we wonder that so sensitive an organ should become irritated and uncertain in its motions. Do not forget this consequence of exocardial disease, especially when recent.

Now, let us turn to the internal condition of the heart. The disorganization of the mitral valve proved, beyond all doubt, that regurgitation to a vast extent must have taken place during the systole. The dyspnœa and hurried respiration declare this as well as the physical signs. Bear in mind the action of the ventricle and valve in a sound heart. The left ventricle contracts on the continued blood which is propelled forward through the aorta, the perfect mitral valve preventing any blood returning backwards into the auricle. During the systole the auricle is filling with blood, coming from the lungs, and the succeeding diastole of the ventricle receives the blood from the auricle, which is again propelled forward as before. But with an imperfect mitral valve, the ventricular contraction sends some blood forward through the aortic canal, but a portion is driven backwards through the imperfect auriculo-ventricular valve into the auricle; the current of blood in the pulmonary veins coming from the lungs is thus retarded, and this obstruction causes pulmonary congestion, cough, and suffocative dyspnœa. Now, in a heart, the movements of which are embarrassed, as this heart has been shown to have been, by pericardial adhesions and deposits of lymph, and where action was known at times to have been unsteady, tumultuous, and irritable, this faulty condition of the mitral valve, co-operating with unsteady and irritable action, might, it is conceived, have produced a fatal condition in the following manner:—A few beats, of increased impulse and power, accompanied by suffocative or pulmonary oppression, are followed by a beat of unsteady force; then the ventricle contracts again with spasmodic energy, drives the blood partially forward, partially backward, regurgitatingly, into, even beyond, the auricle, the backward impulse being felt even in the mouths of the pulmonary veins; so that at the ventricular diastole, the auricle empty, or nearly so, the ventricle receives nothing to stimulate its contractile action, and the whole heart fluttering, and embarrassed, and perturbed by surrounding and external hindrances, as well as by this new internal deficiency of its vital stimulus, and the right side, overloaded by blood accumulating there, unable to move forward from the obstructed state of the pulmonary circulation, the ventricle collapses upon a void, the life-current is arrested, and the patient instantly expires. Such is the brief category of conditions that are believed immediately to have led to dissolution.

This poor girl's case illustrates most forcibly the irresistible progress of inflammation of the heart, when it has proceeded untreated or unchecked for a certain time. I believe that had this case come under treatment twenty-four or even forty-eight hours after the first symptoms of acute rheumatism had developed themselves, in all probability her life might have been spared. Had she been in the hospital thus early, we should have been on the constant watch for cardiac mischief, and ready to combat it the moment it declared itself in the faintest degree, for it is one of the characteristics and advantages of modern practice, that by the aid of the stethoscope, the earliest possible symptom of metastasis to the heart, may, by a watchful ear, be detected. In such cases you must not wait for pain in the chest, or palpitation, or uneasiness in the præcordia, or other complaint from the patient. In every case of acute rheumatism you should never omit to apply the stethoscope at every visit to the region of the heart; be always on the watch for cardiac mischief, the accustomed and educated ear will instantly detect the faintest rubbing murmur or other indication of metastatic inflammation, and will be as quickly ready to combat this fearful enemy to the ultimate safety of the patient. I have every reason to think that all the heart-mischief was perpetrated before the patient was admitted. The physical signs underwent no change, except a partial mitigation, during the time she lived and was under observation. Once or twice there was a decided amelioration of the heart-symptoms; the cupping relieved her, and the aggravated action of the heart was for a time brought down; the opium allayed the constitutional irritability, and assuaged the rheumatic fever; but our chief ally was comparatively inoperative. Faint indications of salivation could with difficulty be obtained, and this, notwithstanding the large quantity of calomel employed. It is nevertheless, instructive to remark, how palpably relieved all the cardiac symptoms instantly became, so soon as the faintest trace of the constitutional operation of mercury was developed; but the full effect of this mineral could not be produced, and the beneficial change could not be sustained. The pathological conpition was more powerful than the mercury could

overcome. Such cases will occur to baffle the best-suggested and most active treatment of our art; but such cases ought not to dishearten us, for they teach us valuable lessons both in pathology and therapeutics; they demonstrate the morbid changes of structure that disease establishes, and they illustrate and develope the principles upon which such cases are to be successfully treated.

The peculiar delicacy and wax-like character of the complexion of this poor girl have already been noticed. It may seem a trifling matter to remark upon, but her general aspect was so illustrative of the old doctrine of the temperament, that I cannot forbear alluding to it. She possessed all the external characteristics of the so-called sanguine temperament, and to which especial susceptibility to acute inflammatory disease was attached. Light flowing auburn hair, fair and alabaster-like complexion, florid cheeks, a symmetrical form, full and early developed, with a mind vivacious and intelligent, and her disease the very concentration of inflammatory intensity. Without meaning to revive or discuss the obsolete question of the temperament, you may, nevertheles, remark, and be prepared to find, that among the youthful who present such characteristics as have been here described, there is a remarkable tendency, and almost special proneness, to acute inflammatory disease; and that when such subjects are attacked by inflammation, it is intense in its degree, often unmanageable, and speedily tends to a fatal termination.

THE LAW OF THE MORPHOLOGY OR METAMORPHOSIS OF THE TEXTURES OF THE HUMAN BODY.

(*Fourth Series of Experimental Researches.*)

By William Addison, M.D., F.R.S., Malvern.

(*Continued from page* 315.)

XIV. Inflammation considered Morphologically.

Before proceeding to substantiate the truth of these conclusions by a microscopical demonstration of the visible changes produced by inflammation, I shall remark upon certain questions which are considered doubtful with respect to the process of nutrition. According to physiologists generally, the lymph, or as I have termed it, the protoplasma of blood, is of the nature of a cyto-blastema, exuding through the interstices of the walls of the nutrient or capillary vessels, somewhat like water through a sieve, and giving origin to cells after its exudation; and upon this hypothesis they explain the origin of pus-cells.

Vogel even attributes a developmental capacity,—i.e., a metamorphic power, not only to coagulable, but to coagulated lymph. The fibrinous fluid of a dropsy, he says, is capable of organization, and "it is indifferent whether the fibrin is in a fluid or coagulated state, as in either case it acts equally well as a cyto-blastema, and its capacity is unlimited." "There may be evolved from the fibrin," he goes on to say, and he is speaking of fibrinous dropsy, "the most different forms of tissue, either normal, as cellular tissue, simple muscular fibre, cartilage, bone, vessel, nervous fibre; or pathological, as pus, granular cells, cancer, tubercle, concretions, &c."*

Speaking of the formation of pus, he says,† "the formation of pus is dependent on two very distinct circumstances. In the first place a fluid *must* be secreted or separated, to act as as a cyto-blastema; and, secondly, the pus-corpuscles *must* be formed in and from this cyto-blastema, which is always the fibrinous fluid, which has already been described in our observations on fibrinous dropsy, *consequently* the formation of pus *must* invariably be preceded by the exudation of a modified blood-plasma." ‡

Again, in another place, "The fibrin may coagulate, and thus give rise to false hydatids, apparent serous dropsy, induration of the affected organ, &c. Then follow the great number of changes which arise from the further development of the fibrin,—suppuration in the widest sense of the word, with all its modifications and forms, the formation of granular cells, and ulceration, epigenesis 'neubildungen' of the most varying kind, tumours, hypertrophies, concretions, changes of colour, softening, induration, &c."§

Dr. J. H. Bennett adopts, if he may not be considered the author of, the views and sentiments expressed by Vogel. "The term exudation," he says, "has been introduced into pathology not only to express the act of the liquor sanguinis (or lymph) passing through the vascular walls, but the fibrinous portion of the liquor sanguinis itself when it has coagulated."
